Final Environmental Impact Statement on the Makah Tribe Request to Hunt Gray Whales

November 2023

U.S. Department of Commerce
National Oceanic and Atmospheric Administration
National Marine Fisheries Service

TITLE OF ENVIRONMENTAL REVIEW	Final Environmental Impact Statement on the Makah Tribe Request to Hunt Gray Whales
RESPONSIBLE AGENCY AND OFFICIAL	National Marine Fisheries Service (NMFS) 1315 East West Highway Silver Spring, MD 20910
COOPERATING AGENCY	U.S. Bureau of Indian Affairs
CONTACT	Grace Ferrara NMFS Protected Resources Division, West Coast Region 7600 Sand Point Way NE, Building 1 Seattle, WA 98115 (206) 526-6172 grace.ferrara@noaa.gov
LOCATION OF PROPOSED ACTIVITIES	The coastal portion of the Tribe's usual and accustomed fishing grounds (U&A), off the northwest coast of Washington State.
PROPOSED ACTION	NMFS proposes to act on the Makah Tribe's request for a waiver of the Marine Mammal Protection Act (MMPA) to resume treaty-based hunting of eastern North Pacific gray whales (*Eschrichtius robustus*) for ceremonial and subsistence purposes.
ABSTRACT	In February 2005, the Makah Indian Tribe submitted to NMFS a request to resume treaty-based hunting of ENP gray whales in the coastal portion of the Tribe's U&A. The Tribe's request stems from the 1855 Treaty of Neah Bay, which expressly secures the Makah Tribe's right to hunt whales. To exercise that right, the Makah Tribe is seeking authorization from NMFS under the Marine Mammal Protection Act and Whaling Convention Act. This final environmental impact statement considers various alternatives to the Tribe's proposed action and principal components associated with a hunt, including: hunt timing and location; the number of whales harvested, struck, and struck and lost; cessation of whale hunting if a predetermined number of identified whales were harvested; the method of hunting; and the duration of regulations and permits.

Executive Summary

The action considered in this final environmental impact statement (FEIS) concerns the Makah Indian Tribe's February 2005 request to resume limited hunting of eastern North Pacific (ENP) gray whales (*Eschrichtius robustus*) in the coastal portion of the Tribe's usual and accustomed fishing grounds (U&A), off the coast of Washington State, for ceremonial and subsistence purposes. The Tribe's proposed action stems from the 1855 Treaty of Neah Bay, which expressly secures the Makah Tribe's right to hunt whales. To exercise that right, the Makah Tribe is seeking authorization from the National Oceanic and Atmospheric Administration's National Marine Fisheries Service (NMFS) under the Marine Mammal Protection Act (MMPA) and the Whaling Convention Act (WCA).

This FEIS, prepared pursuant to the National Environmental Policy Act (42 USC 4321 et seq.), considers various alternatives to the Tribe's proposed action. To develop the full range of action alternatives, we, NMFS, considered the principal components associated with a hunt, including: the time when whale hunting would occur; the area where whale hunting would occur; the annual, six-year, and ten-year limits on the number of whales harvested, struck, and struck and lost; cessation of whale hunting if a predetermined number of Pacific Coast Feeding Group (PCFG) whales were harvested; measures to protect western North Pacific (WNP) gray whales; and the method of hunting. The resultant alternatives are:

- **Alternative 1**, the No-action Alternative, would not authorize a Makah gray whale hunt.
- **Alternative 2**, the Tribe's Proposed Action Alternative, would allow harvest of four ENP gray whales per year on average (with a maximum of five in any one year) and up to 24 whales in any 6-year period. Hunting would be allowed in the Tribe's U&A outside the Strait of Juan de Fuca from December 1 to May 31. Hunting would not be allowed within 200 yards of Tatoosh Island and White Rock. The number of whales that could be struck would be limited to no more than seven in any calendar year and no more than 42 over

the 6-year period, while the number of whales struck and lost would be limited to three annually and 18 over the 6-year period. The maximum number of whales struck in any year would be seven, and the maximum number struck and lost would be three. Under this action alternative, in any year the hunt would cease if a calculated number of PCFG whales (based on the potential biological removal (PPR) formula used in NMFS' MMPA stock assessment reports) were landed and identified. Current calculations result in a harvest limit estimate of 3.0 PCFG whales.

- **Alternative 3** (offshore hunt) would have the same conditions as Alternative 2 regarding numbers of ENP whales struck, struck and lost, and harvested; seasonal restrictions; and regulatory conditions. Alternative 3 would also have the same hunt area as Alternative 2, except that it would prohibit Makah hunters from making an initial strike on a gray whale within 5 miles (8 km) of shore, and assumes an all-motorized hunt with no use of a canoe. Alternative 3 would also differ from Alternative 2 in its approach to managing impacts to the PCFG. It would set an annual total mortality limit for PCFG whales equal to the PBR as applied to PCFG whales in NMFS' most recent MMPA stock assessment report. Current calculations result in a mortality limit estimate of 3.52 PCFG whales. This alternative would also have an additional annual mortality limit for female PCFG whales equal to one-half the PBR.

- **Alternative 4** would have the same conditions as Alternative 2 except the hunting season would be from June 1 through November 30, to avoid killing a WNP whale (because such whales would be feeding in the WNP at this time and not present in the Makah U&A). Because hunting would be allowed during the period that defines membership in the PCFG, Alternative 4 would also include restrictions specifically intended to manage impacts to the PCFG. Key restrictions include avoiding female whales, setting an annual total mortality limit using the PBR approach described for Alternative 3 (but using a lower recovery factor and accounting for other sources of human-caused mortality), and the presumption that all whales struck but not landed are PCFG whales. Current calculations result in a mortality limit estimate of 1 PCFG whale every other year.

- **Alternative 5** would have the same conditions as Alternative 2, except there would be two hunting seasons of 3 weeks each: one from December 1 through December 21 and one from May 10 through May 31. This split-season approach is intended to avoid killing a WNP whale and to minimize the chance of killing a PCFG whale. Alternative 5 would also differ from Alternative 2 by setting an annual PCFG mortality limit at 10 percent of

PBR. Current calculations result in a mortality limit estimate of 0.35 PCFG whales. This alternative would also count any whale struck but not landed as a PCFG whale in proportion to the observed presence of PCFG whales in the Makah U&A during that season.

- **Alternative 6** would have the same conditions as Alternative 2, except that strikes would be limited to seven over 2 years and an annual PCFG mortality limit would be set using the PBR formula as applied to the PCFG in NMFS' most recent stock assessment report (minus other sources of human-caused mortality). Current calculations result in a mortality limit estimate of 2.25 PCFG whales. Alternative 6 would also differ from Alternative 2 by counting all whales struck but not landed against the PCFG limit based on their proportional presence during the season they were struck and lost. In addition, the waiver of the MMPA take moratorium would expire 10 years after adoption, and regulations governing the hunt would limit the term of any hunt permit to not more than 3 years.

- **Alternative 7**, the Preferred Alternative, combines various elements from Alternatives 2 through 6. An alternating winter/spring, summer/fall hunt season would reduce risk to both the PCFG and the endangered WNP gray whale DPS. Like Alternative 6, the waiver would expire after 10 years, and regulations governing the hunt would limit the initial permit period to no more than three years with subsequent permits lasting no more than five years. No more than 25 whales may be struck during the course of the waiver period, with a maximum of three strikes in any given winter/spring hunt and a maximum of two strikes and one landed whale in summer/fall hunts. A limit of 16 PCFG whales may be struck under Alternative 7, up to 8 of which may be females. All struck and lost whales that could not be positively identified in winter/spring hunt years would count against the PCFG strike limit in proportion to their presence in the action are in that season based on recent abundance estimates. All struck whales in summer/fall hunt seasons are presumed to be PCFG whales.

We developed these alternatives and resources for review with input from NMFS staff, the applicant, the Makah Tribe, the cooperating agency (U.S. Bureau of Indian Affairs), and comments from the public. Opportunities for public inspection and comment were provided during the scoping for the draft environmental impact statement (DEIS) (77 FR 29967, May 21, 2012); for a total of 105 days upon the publication of the DEIS (80 FR 13373, March 13, 2015; 80 FR 30676, May 29, 2015); and for a total of 67 days upon the publication of a supplemental DEIS (87 FR 39804, July 5, 2022; 87 FR 50319, August 16, 2022; 87 FR 64454, October 25, 2022). The resources identified during scoping include: water quality, marine habitat and species, gray whales, other wildlife

species, economics, environmental justice, social environment, cultural resources, ceremonial and subsistence resources, noise, aesthetics, transportation, public services, public safety, human health, and the national and international regulatory environment. Table ES-1 summarizes the results of our analysis, using Alternative 1 (the No-action Alternative) as the baseline for assessing the impacts on the various resources.

This FEIS identifies Alternative 7 as the Preferred Alternative and addresses public comments received on the DEIS and SDEIS. Frequent and substantive comments are summarized and responses are provided in Appendix C. These comments, in conjunction with considerations described in this FEIS, will provide information to assist NMFS with its decision-making on the Tribe's request.

This FEIS is being prepared using the 1978 CEQ NEPA Regulations. NEPA reviews initiated prior to the effective date of the 2020 CEQ regulations may be conducted using the 1978 version of the regulations. The effective date of the 2020 CEQ NEPA Regulations was September 14, 2020. This review began on May 21, 2016 with the publication of the Notice of Intent, and the agency has decided to proceed under the 1978 regulations.

Table ES-1 – Summary of Impacts from the Action Alternatives Analyzed in this FEIS Relative to the No-Action Alternative. Refer to Section 4 and Table 4-17 for more detailed narrative associated with our analysis of the various alternatives and resources.

Resources	No Action Alternative	Impact and Magnitude Relative to No-action Alternative
Ground Water	Current risk levels would continue.	No impacts to ground water, including drinking water sources, are expected under any of the action alternatives.
Marine Waters	Current risk levels would continue (includes occasional disposal of drift whale carcasses).	None of the action alternatives are likely to have more than minor, temporary effects on marine water quality. The risk of such effects is highest under Alternative 2 and lowest under Alternative 4.
Pelagic Species and Communities	Current levels of disturbance would continue.	None of the action alternatives have the potential to appreciably affect pelagic habitats. The risk of any effects is highest under Alternative 2 and lowest under Alternative 4.
Benthic Species and Communities	Current levels of disturbance would continue.	None of the action alternatives have the potential to appreciably affect benthic habitats. The risk of any effects is highest under Alternative 2 and lowest under Alternative 4.
ENP Gray Whale Stock	Current IWC-set catch limits would continue. ENP gray whale stock is likely to remain at or near carrying capacity.	None of the action alternatives are likely to increase the risk of adverse impacts on the ENP gray whale stock.
WNP Gray Whale Stock	The IWC has not set a catch limit for WNP gray whales.	Although the risk of impacting the WNP gray whale stock is low under all of the action alternatives, they all (except Alternative 4, under which hunting is unlikely to encounter WNP whales) pose some degree of risk, with Alternative 2 posing the most risk and Alternative 4 presenting the least risk.
PCFG Gray Whales	No hunting would occur in the PCFG seasonal range.	All action alternatives are likely to increase the risk of adverse impacts on PCFG gray whales. Alternative 2 would increase this risk the most, while Alternative 5 would likely increase it the least. Even under Alternative 2, however, the best available information indicates that the PCFG would remain viable.

Resources	No Action Alternative	Impact and Magnitude Relative to No-action Alternative
Gray Whales Using the Makah U&A and OR-SVI Areas	No hunting would occur in local survey areas.	All action alternatives are likely to increase the risk of adverse impacts on gray whales using local survey areas. Alternative 2 would likely have the most risk, while Alternative 5 would likely have the least risk. None of the alternatives are expected to deter gray whales from continuing to use these survey areas.
Individual Whales	On average, 124 whales could be harvested in the Chukotkan hunt annually, experiencing manner and time to death particular to that hunt. Approximately 3 percent would be struck and lost.	All action alternatives are likely to increase the risk of adverse impacts on individual gray whales. Alternative 2 would likely have the most risk, while Alternative 4 would likely have the least risk.
Marine Mammals	Current levels of disturbance would continue.	All action alternatives could increase the risk of adverse impacts on marine mammals. Alternative 2 would likely have the most risk, while Alternative 5 would likely have the least risk. Any impacts are likely to be temporary and are unlikely to have lasting effects on individuals or populations.
Other Marine Wildlife	Current levels of disturbance would continue.	All action alternatives could increase the risk of adverse impacts on other marine wildlife, although none are expected to have lasting effects. Alternative 2 would likely have the most risk of adverse impacts, while Alternative 5 would likely have the least risk.
Tourism	No opportunity for Tribe to promote hunt-related tourism and no likelihood of hunt-related boycott. Potential for small disproportionate effect on Tribe.	All action alternatives are likely to have a mix of beneficial and adverse impacts on tourism. Alternative 2 would have the greatest likelihood of mixed impacts, while Alternative 4 would have the least.
Household Use of Whale Products	Current limited availability of drift whales and whales incidentally caught in fishing operations (potentially one whale every 10 years).	All action alternatives are likely to have beneficial impacts on household use of whale products. Alternative 2 would likely have the most impact, while Alternative 4 would likely have the least impact.
Whale-watching Industry	Current levels of revenues from, and employment in, whale-watching industry would continue.	None of the action alternatives are likely to increase the risk of adverse impacts on the whale-watching industry.
Shipping and Ocean Sport/ Commercial Fishing	Current passage conditions for ships and fishing vessels would continue.	While none of the action alternatives are expected to have more than a negligible impact on shipping or commercial fishing, they could increase the risk of adverse impacts, with Alternative 3 having the most risk of adverse impacts and Alternative 4 having the least.

Resources	No Action Alternative	Impact and Magnitude Relative to No-action Alternative
Management and Law Enforcement	No change from current conditions.	All action alternatives are likely to increase the management and law enforcement costs. Alternative 2 would likely have the greatest cost, while Alternative 4 would likely have the lowest cost.
Economics	Current levels of tourism would continue. Current occasional household use of products from drift whales and whales incidentally caught in fishing operations (potentially one whale every 10 years).	All action alternatives are likely to have a mix of beneficial and adverse impacts on economics, but an overall a negligible impact. Alternative 2 would have the greatest likelihood of mixed impacts, while Alternative 4 would have the least.
Ceremonial and Subsistence Resources	Current limited availability of drift whales and whales incidentally caught in fishing operations (potentially one whale every 10 years). Lack of access to resource has disproportionate impact on Tribe.	All action alternatives are likely to have beneficial impacts on ceremonial and subsistence resources. Alternative 2 would likely have the most beneficial impact, while Alternative 4 would likely have the least beneficial impact.
Social Environment	Potential for tension between Makah Tribe and others, including federal government.	All action alternatives are likely to have a mix of beneficial and adverse impacts on the social environment. Alternative 2 would have the greatest likelihood of mixed impacts, while Alternative 4 would have the least.
Makah Tribal Members, Other Tribes, and Other Individuals and Organizations	Likely no protests and related social tensions. No change from current level of tension between members opposed to the hunt and those supporting it. The latter may feel continued frustration with U.S. government.	All action alternatives are likely to have a mix of beneficial and adverse impacts on Makah tribal members, other tribes, and other individuals and organizations. Alternative 2 would have the greatest likelihood of mixed impacts while Alternative 4 would have the least.
Sites with Cultural Significance	No change from current conditions.	All action alternatives are likely to have a mix of beneficial and adverse impacts on sites with cultural significance. Alternative 2 would have the greatest likelihood of mixed impacts, while Alternative 4 would have the least.
Access to Whale Hunting Opportunities	No change from current conditions, i.e., no access to whale hunting opportunities.	All action alternatives are likely to have beneficial impacts on access to whale hunting opportunities. Alternative 2 would likely have the most beneficial impact, while Alternative 4 would likely have the least beneficial impact.

Resources	No Action Alternative	Impact and Magnitude Relative to No-action Alternative
Subsistence Use	The Tribe could pursue some subsistence uses of whales (such as using drift whales or whales incidentally caught in fishing operations), but they would have limited cultural value if not practiced in connection with actual whale hunts.	All action alternatives are likely to have beneficial impacts on subsistence use of whale products. Alternative 2 would likely have the most beneficial impact, while Alternative 4 would likely have the least beneficial impact.
Traditional Knowledge and Activities	The Tribe could continue to engage in many related activities, and could apply and transmit relevant knowledge, but this would have limited cultural value if not practiced in connection with actual whale hunts. Application and transfer of knowledge related to actual hunting would be limited to discussions of past whale hunting.	All action alternatives are likely to have beneficial impacts on traditional knowledge and activities. Alternative 2 would likely have the most beneficial impact, while Alternative 4 would likely have the least beneficial impact.
Spiritual Connection to Whaling	Spiritual connection to whaling would continue to be limited to connection to past whaling and spiritual connection may eventually wane.	All action alternatives are likely to have beneficial impacts on the Tribe's spiritual connection to whaling.
Cultural Identity	Tribal identity could erode in the absence of opportunities to participate in an activity central to Makah cultural identity.	All action alternatives are likely to have beneficial impacts on the Tribe's cultural identity.
Noise Levels at Receiving Properties	No change from current conditions.	All action alternatives are likely to increase the risk of adverse impacts on noise levels at receiving properties. Alternative 2 would likely have the most increased risk, while Alternative 4 would likely have the least increased risk.
On-scene Observers	Current lack of opportunity to view an authorized whale hunt would continue.	All action alternatives are likely to have a mix of beneficial and adverse impacts on on-scene observers. Alternative 2 would have the greatest likelihood of mixed impacts, while Alternative 4 would have the least.
Media Observers	Current lack of opportunity to view an authorized whale hunt would continue.	All action alternatives are likely to have a mix of beneficial and adverse impacts on media observers. Alternative 2 would have the greatest likelihood of mixed impacts, while Alternative 4 would have the least.
Highway, Marine, and Air Traffic	No change from current conditions.	All action alternatives are likely to increase the risk of adverse impacts on highway, marine, and air traffic. Alternative 2 would likely have the most risk, while Alternative 4 would likely have the least risk.

Resources	No Action Alternative	Impact and Magnitude Relative to No-action Alternative
Law Enforcement and Medical Facilities	No change from current conditions.	All action alternatives could increase the risk of adverse impacts on law enforcement and medical facilities. Alternative 2 would likely have the most risk, while Alternative 4 would likely have the least risk.
Injury from Weapons, Boating Accidents, and Land-based Protest Activities	No change from current conditions.	All action alternatives are likely to increase the risk of adverse impacts because of injury from weapons, boating accidents, and land-based protest activities. Alternative 2 would likely have the most increased risk, while Alternative 4 would likely have the least risk increase.
Nutritional Benefits, Environmental Contaminants, and Exposure to Food-borne Pathogens	No change from current conditions.	All action alternatives are likely to have a mix of beneficial and adverse impacts associated with nutritional benefits, environmental contaminants, and exposure to food-borne pathogens. Alternative 2 would have the greatest likelihood of mixed impacts, while Alternative 4 would have the least.
Marine Mammals Nationally	It is uncertain, but possible, that a decision not to authorize a Makah whale hunt could discourage future requests for a waiver of the MMPA.	It is uncertain what, if any, impacts the action alternatives are likely to have on the national regulatory environment for marine mammals.
Worldwide Whaling	A U.S. decision not to authorize a Makah whale hunt is unlikely to influence the position of the United States or other countries regarding IWC issues.	It is uncertain what, if any, impacts the action alternatives are likely to have on worldwide whaling.

WAC	Washington Administrative Code
WCA	Whaling Convention Act
WDFW	Washington Department of Fish and Wildlife
WNP	western North Pacific
ww	wet weight

Glossary

.50 and .577 caliber rifle = High-powered rifles designed to shoot a bullet of diameter 0.5 inches or 0.577 inches, respectively.

Aboriginal subsistence whaling = As defined in regulations implementing the Whaling Convention Act, aboriginal subsistence whaling refers to whaling authorized by paragraph 13 of the Schedule annexed to and constituting a part of the Convention (i.e., International Convention for the Regulation of Whaling). The Schedule does not otherwise define aboriginal subsistence whaling, but the International Whaling Commission adopted the following definition of subsistence use by consensus at its 2004 annual meeting: (1) The personal consumption of whale products for food, fuel, shelter, clothing, tools, or transportation by participants in the whale harvest; (2) The barter, trade, or sharing of whale products in their harvested form with relatives of the participants in the harvest, with others in the local community or with persons in locations other than the local community with whom local residents share familial, social, cultural, or economic ties. A generalized currency is involved in this barter and tra[d]e, but the predominant portion of the products from each whale are ordinarily directly consumed or utilized in their harvested form within the local community; (3) The making and selling of handicraft articles from whale products, when the whale is harvested for the purposes defined in (1) and (2) above. General principles governing aboriginal subsistence whaling are contained in the Schedule.

Aboriginal subsistence whaling quota = Number of whales that may be taken by a Native American whaling organization for subsistence uses.

Adaptive management plan = A management approach wherein a plan is changed and improved in response to lessons learned during plan implementation.

Alaska Eskimos/Alaska Natives = A group of native people living in the Arctic coastal regions of Alaska.

Algal bloom = A rapid and often visible increase in the population of (usually) phytoplankton algae in an aquatic system.

Allowable Bycatch Level (ABL) = As defined in the Makah Tribe's waiver request, the number of whales from the Pacific Coast Feeding Group (PCFG) that may be taken incidental to a hunt directed at the migratory portion of the Eastern North Pacific stock of gray whales. The ABL is calculated using the Marine Mammal Protection Act's potential biological removal approach but

the minimum population estimate is calculated from the number of previously seen whales in the Oregon-Southern Vancouver Island survey area.

Ancestral villages = A settlement that has been inhabited for many generations.

Ancient canoe runs = Sub- and inter-tidal areas where it is possible to see old pathways perpendicular to the shoreline that were cleared of boulders and cobbles to allow canoes to reach shore without being damaged.

Approach= causing a hunting or training vessel to be within 100 yards of a gray whale.

Baleen whale = A whale of the Suborder Mysteceti whose members have comb-like baleen plates (instead of teeth) which enable them to filter food from the water. As defined by the July 2012 Schedule to the International Convention for the Regulation of Whaling, baleen whale means any whale which has baleen or whale bone in the mouth (i.e. any whale other than a toothed whale).

Benthic = Living on the bottom of the ocean.

Benthos = The collection of organisms living on the bottom of the ocean.

Bequians = Inhabitants of Bequia, the second largest of the thirty-two islands and cays that make up the island state of St. Vincent & the Grenadines.

Bilateral agreement = An agreement between two countries detailing their mutual understanding, policies, and obligations on a particular matter.

Bunker fuel = A common and often low grade fuel used to power cargo ships.

Bureau of Indian Affairs = A United States agency within the Department of the Interior charged with the administration and management of land held in trust by the United States for American Indians, Indian tribes and Alaska Natives. In addition, the Bureau of Indian Affairs provides education services to approximately 48,000 Indians.

Calf (whale) = As defined by regulations implementing the Whaling Convention Act, a calf is any whale less than 1-year old or having milk in its stomach.

Cervical and cranial thoracic regions = Relating to the neck (cervical) or skull (cranial) in the chest (thoracic) region of a whale.

Cetacean = Refers to an animal belonging to the order Cetacea, which includes sea mammals such as whales and dolphins.

Chase boat = According to the Makah waiver request, a powered boat that assists in the whale hunt by staying in close proximity to the whaling crew in the canoe and towing a harvested whale to shore. In the Makah proposal each chase boat would be manned by a pilot, diver, rifleman, backup harpooner, and at least one other crew member, and would be equipped with a navigation system capable of fixing the vessel's position on the water.

Chukotka natives = Aboriginal people located in the far northeast of the Russian Federation.

Coastal Zone Management Act (CZMA) = A United States law that encourages coastal states to develop and implement coastal zone management plans to protect and enhance coastal zone resources.

Code of Federal Regulations (CFR) = The United States government's codification of the general and permanent rules and regulations (sometimes called administrative law) published in the Federal Register by the executive departments and agencies of the United States Federal Government. The CFR is published by the Office of the Federal Register, an agency of the National Archives and Records Administration.

Contracting Government = A country/government party to the International Convention for the Regulation of Whaling.

Cooperative agreement = As defined by regulations implementing the Whaling Convention Act, a cooperative agreement is a written agreement between the National Oceanic and Atmospheric Administration and a Native American whaling organization for the cooperative management of aboriginal subsistence whaling operations.

Council on Environmental Quality (CEQ) = A division of the White House established as part of the National Environmental Policy Act of 1969. The CEQ issues an annual report to the President of the United States on the state of the environment; coordinates United States environmental efforts and works closely with agencies and other White House offices in the development of environmental and energy policies and initiatives; oversees federal agency implementation of the environmental impact assessment process; and acts as a referee when agencies disagree over the adequacy of such assessments.

Cultural Anthropology Panel = A group of experts in cultural anthropology convened by the International Whaling Commission in 1979 to discuss the Alaska Eskimo bowhead hunts.

Darting gun = A hand thrown device consisting of a barrel (to hold an explosive projectile) that is attached to a wooden shaft equipped with a toggle-point harpoon. The barrel contains a trigger rod that ignites a propellant or 'pusher' charge which fires the explosive projectile into the whale's body.

Decibels = A unit of measurement for sounds, in particular the loudness of sounds.

Delegates = Members of delegations, headed by commissioners, representing member nations that are party to the International Whaling Commission.

Deoxyribonucleic acid (DNA) = A large, double-stranded, helical molecule found in the nucleus of cells that carries the genetic code for an organism.

Dispatch = To kill a whale with a rifle or penthrite grenade.

Diver = According to the Makah waiver request, a member of the whaling crew whose duties include diving into the water from the chase boat to attempt to sew a whale's mouth shut to prevent the whale from sinking after it has been struck by the harpooner and shot by the rifleman.

Drift whale = A whale that dies naturally or as a result of some human activity other than a directed hunt (for example, entanglement in fishing gear).

Eastern North Pacific (ENP) gray whales = Gray whales that feed during the summer and fall primarily in the Chukchi, Beaufort, and northwestern Bering Seas, but also as far south as California. ENP gray whales are considered a population stock under the MMPA. ENP gray whales were formerly listed as an endangered species under the ESA but subsequently recovered and were delisted in 1994 (59 FR 31094, June 16, 1994).

Ecotourism = Tourism that focuses on the natural ecological attributes of an area (e.g., whale-watching) and their preservation.

Ecotype = A subgroup of a species that is differentiated from other subgroups by distinct adaptations to a particular habitat.

Eight-gauge shoulder gun = A shoulder-mounted firearm with a long, smooth-bore barrel capable of shooting a 0.835-inch projectile.

Endangered species = As defined in the Endangered Species Act, an endangered species means any species which is in danger of extinction throughout all or a significant portion of its range.

Endangered Species Act (ESA) = A United States law that provides for the conservation of endangered and threatened species of fish, wildlife, and plants.

Endangered species list = The List of Endangered and Threatened Wildlife (50 CFR 17.11; 50 C.F.R. §§ 223.201, 224.101), and the List of Endangered and Threatened Plants (50 CFR 17.12; 50 C.F.R. §§ 223.201, 224.101) name all species of mammals, birds, reptiles, amphibians, fishes, insects, plants, and other creatures that have been determined by the National Marie Fisheries Service or the United States Fish and Wildlife Service to be in the greatest need of Federal protection. Once listed, a species receives the full range of protections available under the Endangered Species Act, including prohibitions on killing, harming or otherwise taking a species.

Environmental Assessment (EA) = In the context of National Environmental Policy Act, an EA is a concise public document that analyzes the environmental impacts of a proposed Federal action and provides sufficient evidence to determine the level of significance of the impacts. The EA includes a brief analysis of the environmental impacts of the proposed action and its alternatives, and results in one of two determinations: (1) an Environmental Impact Statement is required; or (2) a Finding of No Significant Impact.

Environmental Impact Statement (EIS) = A detailed written statement required by the National Environmental Policy Act and prepared by a federal agency. The EIS is used by decision-makers to take environmental consequences into account. It describes a proposed action, the need for the action, alternatives considered, the affected environment, the environmental impacts of the proposed action, and other reasonable alternatives to the proposed action. An EIS is prepared in two stages: a draft and a final.

Environmental Protection Agency (EPA) = A United States agency responsible for protecting human health and the environment.

Eskimos = See Alaska Eskimos.

Evolutionarily significant unit (ESU) = A concept the National Marine Fisheries Service uses to identify distinct population segments of Pacific salmon under the Endangered Species Act. An ESU is a population or group of populations of Pacific salmon that (1) is substantially reproductively isolated from other populations and (2) contributes substantially to the evolutionary legacy of the biological species.

Exclusive economic zone (EEZ) = A coastal zone under national jurisdiction (up to 200-nautical miles wide) declared under the provisions of the 1982 United Nations Convention of the Law of the Sea, within which the United States has the rights over the use and exploration of marine resources. The United States EEZ in the northern portion of the Makah Usual and Accustomed fishing grounds is much narrower than 200 nautical miles due to the international boundary with Canada.

Federal Register = The United States government's daily publication of federal agency regulations and documents, including presidential proclamations, executive orders, and documents that must be published per acts of Congress.

Finding of No Significant Impact (FONSI) = A short National Environmental Policy Act document that presents the reasons why an action will not have a significant impact on the quality of the human environment and, therefore, will not require preparation of an Environmental Impact Statement. A Finding of No Significant Impact must be supported by the Environmental Assessment.

First Nation = A term referring to the aboriginal people located in what is now Canada.

Flense = To strip the blubber or skin from a dead whale.

Floats = Air-filled buoys attached by ropes to a struck or dead whale using a harpoon with a toggle point head. The floats keep the whale on the water surface so that it can be towed to shore for butchering.

Harassment = As defined in regulations implementing the Marine Mammal Protection Act, harassment means any act of pursuit, torment, or annoyance which: (1) has the potential to injure a marine mammal or marine mammal stock in the wild; or (2) has the potential to disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering. In the case of a military readiness activity or a scientific research activity conducted by or on behalf of the Federal Government, the term harassment means (1) any act that injures or has the significant potential to injure a marine mammal or marine mammal stock in the wild; or (2) any act that disturbs or is likely to disturb a marine mammal or marine mammal stock in the wild by causing disruption of natural behavioral patterns, including, but not limited to, migration, surfacing, nursing, breeding, feeding, or sheltering, to a point where such behavioral patterns are abandoned or significantly altered.

Harpooner = According to the Makah waiver request, a member of the whaling crew whose duties include throwing a long spear-like harpoon at a whale in order to embed a steel barb and

its accompanying line and floats into the animal. A backup harpooner accompanies a separate crew on the tribal chase boat.

Harvest = To kill and land a whale.

Haulout = A site where seals, sea lions, and other marine mammals climb out of the water to rest on land.

Hertz = A measurement of vibration or frequency expressed in cycles per second. One hertz equals one cycle per second.

Humane = As defined in regulations implementing the Marine Mammal Protection Act, the term humane refers to that method of taking which involves the least possible degree of pain and suffering practicable to the mammal involved.

Identified whale = An individual gray whale that has been identified from photographs and cataloged using a code unique to that animal.

Indian Civil Rights Act = A United States law that prohibits Indian tribal governments from enacting or enforcing laws that violate certain individual rights. It was adopted by the United States Congress to ensure that tribal governments respect basic rights of Indians and non-Indians.

International Convention for the Regulation of Whaling (ICRW) = An international treaty (also referred to as the "Convention") signed in 1946 designed to "provide for the proper conservation of whale stocks and thus make possible the orderly development of the whaling industry." A focus of the treaty was the establishment of the International Whaling Commission. There are presently 79 member nations to the ICRW, including the United States.

International Whaling Commission (IWC) = A body of commissioners charged with carrying out the provisions of the ICRW.

IWC aboriginal subsistence whaling = See Aboriginal subsistence whaling

IWC Commercial Whaling Moratorium = A moratorium on all commercial whaling approved by the International Whaling Commission in 1982 which effectively expanded the 1937 ban on commercial harvest of gray whales and right whales to all large whale species.

IWC Scientific Committee = A part of the International Whaling Commission (IWC), this group consists of approximately 200 of the world's leading whale scientists who provide advice

on the status of whale stocks. The IWC Scientific Committee meets in person biennially for two weeks 3-4 months preceding the main International Whaling Commission meeting. The Scientific Committee also calls special in-person and virtual meetings as needed to address particular subjects.

Land/Landing = As defined by regulations implementing the Whaling Convention Act, landing means bringing a whale or any parts thereof onto the ice or land in the course of whaling operations.

Landfill = A place where solid waste (garbage) is disposed between layers of dirt.

Level A harassment = As defined in regulations implementing the Marine Mammal Protection Act, Level A harassment means any act of pursuit, torment, or annoyance which has the potential to injure a marine mammal or marine mammal stock in the wild. In the case of a military readiness activity or a scientific research activity conducted by or on behalf of the Federal Government, the term Level A harassment means any act that injures or has the significant potential to injure a marine mammal or marine mammal stock in the wild.

Level B harassment = As defined in regulations implementing the Marine Mammal Protection Act, Level B harassment means any act of pursuit, torment, or annoyance which has the potential to disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering. In the case of a military readiness activity or a scientific research activity conducted by or on behalf of the Federal Government, the term Level B harassment means any act that disturbs or is likely to disturb a marine mammal or marine mammal stock in the wild by causing disruption of natural behavioral patterns, including, but not limited to, migration, surfacing, nursing, breeding, feeding, or sheltering, to a point where such behavioral patterns are abandoned or significantly altered.

Local aboriginal consumption = A phrase defined by the 1981 *Ad Hoc* Technical Working Group (but not formally adopted by the International Whaling Commission) to mean traditional uses of whale products by local aboriginal, indigenous or native communities in meeting their nutritional, subsistence and cultural requirements. The term includes trade in items which are by-products of subsistence catches.

Lose = As defined by the July 2012 Schedule to the International Convention for the Regulation of Whaling, lose means to either strike or take but not to land. ('Take' has a distinct meaning in the Marine Mammal Protection Act and International Convention for the Regulation of Whaling.)

Maa-Nulth First Nations = The Maa-nulth First Nations comprise five First Nations from Vancouver Island. They include: Huu-ay-aht First Nations, Ka:'yu:'k't'h'/Che:k'tles7et'h First Nations, Toquaht Nation, Uchucklesaht Tribe, and the Ucluelet First Nation. Maa-nulth means "villages along the coast" in the Nuu-chah-nulth language. These villages/territories are located on the west coast of Vancouver Island surrounding Barkley Sound and Kyuquot Sound.

Makah Tribal Council = The governing body of the Makah Tribe. In three cooperative agreements with the Makah Tribe (in 1996, 1997, and 2001) the National Oceanic and Atmospheric Administration recognized the Makah Tribal Council as a Native American whaling organization and allowed the Council to issue permits to whaling captains in compliance with the cooperative agreements and Whaling Convention Act regulations.

Makah U&A whales= PCFG whales observed in either the northern Washington survey area (from Cape Alava to Cape Flattery) or Strait of Juan de Fuca survey area (from Cape Flattery to Admiralty Inlet) from June 1 to November 30.

Makah Whaling Commission = Members of the Makah Tribe that serve to review whaling crew qualifications, identify whaling crew and vessel participation, and provide other hunt restrictions and recommendations. The Makah Tribal Council would issue the permit to a whaling captain before any hunt, based on recommendations from the Makah Whaling Commission.

Maktak = Whale skin and layer of blubber used for food.

Magnuson Stevens Act (MSA) = Also known as the Magnuson-Stevens Fishery Conservation and Management Reauthorization Act of 2006. A United States law that is the governing authority for all fishery management activities that occur in federal waters within the United States 200 nautical mile limit, or Exclusive Economic Zone. The recent reauthorization mandates the use of annual catch limits and accountability measures to end overfishing, provides for widespread market-based fishery management through limited access programs, and calls for increased international cooperation.

Marine Mammal Commission (MMC) = An independent agency of the United States Government, established under Title II of the Marine Mammal Protection Act. The MMC was created to provide independent, science-based recommendations to the Secretary of Commerce on domestic and international programs and policies with respect to marine mammal protection and conservation and to carry out research programs.

Marine Mammal Protection Act (MMPA) = A United States law that prohibits, with certain exceptions, the take of marine mammals in United States waters and by United States citizens on

the high seas, and the importation of marine mammals and marine mammal products into the United States

Maximum Net Productivity Level (MNPL) = A population level related to maximum net productivity, a rate of change defined in the National Marine Fisheries Service's Marine Mammal Protection Act regulations as the greatest net annual increment in population numbers or biomass resulting from additions to the population due to reproduction and/or growth less losses due to natural mortality.

Mitochondrial deoxyribonucleic acid (mtDNA) = DNA that is found in the mitochondria of cells. Unlike nuclear DNA, mtDNA is only inherited through the mother.

Moratorium = See IWC Commercial Whaling Moratorium

Moving Exclusion Zone (MEZ) = As defined in United States Coast Guard regulations, the MEZ is a vessel-based buffer within the Regulated Navigation Area designed to promote the safety of the whaling crew and other persons/watercraft operating in the vicinity of the whaling crew. The MEZ includes the column of water from the surface to the seabed with a radius of 500 yards centered on the Makah whale hunt vessel. Unless otherwise authorized by the Coast Guard, no person or vessel may enter the active MEZ except for an authorized Makah whale hunt and certain authorized media pool vessels.

Muzzle break = A device fitted to the end of the barrel that reduces gun recoil by re-directing gases that propel the bullet.

National Environmental Policy Act (NEPA) = A United States law declaring that it is the continuing policy of the Federal government to use all practicable means to create and maintain conditions under which people and nature can exist in productive harmony and fulfill the social, economic, and other needs of present and future generations of Americans. NEPA provides a mandate and a framework for Federal agencies to consider all reasonably foreseeable environmental effects of their proposed actions and to involve and inform the public in the decision-making process.

National Marine Fisheries Service (NMFS) = A United States agency within the National Oceanic and Atmospheric Administration and under the Department of Commerce charged with the stewardship of living marine resources through science-based conservation and management, and the promotion of healthy ecosystems.

National Oceanic and Atmospheric Administration (NOAA) = A scientific agency of the United States Department of Commerce focused on the conditions of the oceans and the atmosphere. NOAA warns of dangerous weather, charts seas and skies, guides the use and protection of ocean and coastal resources, and conducts research to improve understanding and stewardship of the environment. NOAA manages 13 National Marine Sanctuaries, including the Olympic Coast National Marine Sanctuary.

NOAA Office of International Affairs = An office within the National Oceanic and Atmospheric Administration that develops, coordinates, and promotes United States international policies in NOAA-related matters such as ecosystem-based management, climate change, earth observation, and weather forecasting.

Native American whaling organization = As defined by Whaling Convention Act regulations, an entity recognized by NMFS (e.g., the Makah Tribe) as representing and governing the relevant Native American whalers for the purposes of cooperative management of aboriginal subsistence whaling.

Non-binding resolution = A written motion adopted by a deliberative body (e.g., the United States Congress) that does not progress into a law but instead serves to formally express an opinion.

Observer = According to the Makah waiver request, a member of the Makah Department of Fisheries Management whose duties include observing the hunt and photographing any whale landed.

Occipital condyle = Skull bones located at the back and lower part of the cranium near the attachment of the spinal column.

Olympic Coast National Marine Sanctuary (OCNMS) = One of 13 marine sanctuaries in the United States administered by NOAA. It was designated as the first National Marine Sanctuary in the Pacific Northwest in 1994 and encompasses 3,310 square miles off of Washington State's Olympic Peninsula, extending 135 miles along the Washington Coast from about Cape Flattery to the mouth of the Copalis River.

Olympic National Park = A large national park located on Washington's Olympic Peninsula and managed by the United States National Park Service. Originally designated as the Olympic National Monument in 1909, it was re-designated a National Park in 1938 and became a World Heritage Site in 1981.

Optimum sustainable population (OSP) = As defined by regulations implementing the Marine Mammal Protection Act, the term optimum sustainable population means, with respect to any population stock, the number of animals which will result in the maximum productivity of the population or the species, keeping in mind the carrying capacity of the habitat and the health of the ecosystem of which they form a constituent element.

Oregon to Southern Vancouver Island (OR-SVI) = An area surveyed for whales within the Pacific Coast Feeding Group range and encompassing coastal marine waters from Oregon to southern Vancouver Island, B.C.

Oregon to Southern Vancouver Island (OR-SVI) whales = PCFG whales observed in any survey area from southern Oregon to southern Vancouver Island (excluding areas in Puget Sound) from June 1 to November 30.

Pacific Coast Feeding Group (PCFG) range = A coastal marine area from northern California to northern Vancouver Island, B.C, used by PCFG gray whales.

Pacific Coast Feeding Group (PCFG) whales = Gray whales observed in at least 2 years between June 1 and November 30 in the PCFG area (along the U.S. and Canada coasts between 41°N and 52°N, excluding areas in Puget Sound) and entered into the Cascadia Research Collective's photo-identification catalog. For purposes of determining whether a harvested whale is a PCFG whale and therefore counts against a bycatch or mortality limit, the Tribe's proposal under Alternative 2 would include cataloged whales seen in at least 1 year, while the other action alternatives would include cataloged whales seen in 2 or more years. Under the MMPA, PCFG whales are considered part of the ENP gray whale population stock and have been described in the ENP gray whale SARs as a feeding aggregation.

Pacific Coast Feeding Group (PCFG) Mortality Limit = Term used in this FEIS to refer to calculated limits on all hunt-related mortality (i.e., whales that are struck and lost as well as whales that are landed) of Pacific Coast Feeding Group (PCFG) whales.

Pacific Fishery Management Council (PFMC) = One of eight regional fishery management councils established by the Magnuson Fishery Conservation and Management Act of 1976 for the purpose of managing fisheries from 3-200 miles offshore of the United States of America coastline. The PFMC is responsible for fisheries off the coasts of California, Oregon, and Washington.

Panmixia = The random mating of individuals within a population.

Pelagic = Of or in the upper layers of the open ocean.

Penthrite = Pentaerythritol tetranitrate or PETN. An odorless white crystalline solid used as a powerful explosive. Employed in whale hunting as a "penthrite grenade" discharged from a harpoon cannon.

Petroglyph = An ancient picture or inscription drawn or carved into a rock.

Pilot = According to the Makah waiver request, a member of the whaling crew whose duties include navigating the chase boat.

Plenary session = That portion of the annual International Whaling Commission meeting during which the full body of commissioners (or their deputy/alternate) debate and vote on proposals, resolutions, and motions before the International Whaling Commission.

Plenary power = Complete and unlimited power.

Pods = Small groups of marine mammals, especially whales.

Polychlorinated biphenyls (PCBs) = A class of toxic organic compounds known to accumulate in animal tissue. PCBs were primarily used as cooling and insulating fluids for industrial transformers and capacitors prior to being banned in the United States in the 1970s.

Potential Biological Removal Level (PBR) = As defined by regulations implementing the Marine Mammal Protection Act, the term PBR level means the maximum number of animals, not including natural mortalities, that may be removed from a marine mammal stock while allowing that stock to reach or maintain its optimum sustainable population level. The PBR level is the product of the following factors: (1) The minimum population estimate of the stock; (2) One-half the maximum theoretical or estimated net productivity rate of the stock at a small population size; (3) A recovery factor of between 0.1 and 1.0.

Potlatch = A ceremonial gathering and gift-giving feast practiced by the Makah and other tribes of the Pacific Northwest that helps establish important proprietary rights regarding ownership of dances, songs, and other ceremonial and economic privileges.

Precedential effects = The effects of an action that would set a precedent for similar actions in the future.

Pupping = To give birth to pup seals or sea lions.

Record of Decision (ROD) = A National Environmental Policy Act document signed by the agency decisionmaker following the completion of an EIS. The ROD contains the decisions, alternatives considered, environmentally preferable alternative(s), factors considered in the agency's decisions, mitigation measures to be implemented; it also indicates whether all practicable means to avoid or minimize environmental harm have been adopted.

Recruitment = The process of adding individual whales to a population, group or area (usually by reproduction but also by migration).

Regulated navigation area (RNA) = As defined in United States Coast Guard regulations, the RNA is a marine zone the United States Coast Guard established within which the Makah whaling crew can activate a MEZ. The RNA promotes the safety of the whaling crew and other persons/watercraft operating in the vicinity of the whaling crew.

Regional Administrator = A National Marine Fisheries Service official who, among other duties, has been delegated authority to make the initial waiver determination under the Marine Mammal Protection Act on the Makah waiver request.

Rifleman = According to the Makah waiver request, a member of the whaling crew whose duties include shooting a harpooned whale using a high-powered rifle.

Rookeries = Sites where seals and sea lions congregate on shore to mate and give birth.

Russian Federation = A federation of independent states in northeastern Europe and northern Asia; formerly the Soviet Union.

Safety officer = According to the Makah waiver request, a member of the whaling crew whose duties include determining when the rifleman or whaler can discharge their weapon.

Salvage = To collect and utilize a dead, unclaimed whale.

Schedule = A document maintained by the International Whaling Convention that governs the conduct of whaling throughout the world. The measures described in the Schedule, among other things, provide for the protection of certain species; designate specified areas as whale sanctuaries in which commercial whaling may not occur if it were to resume; set limits on the numbers and size of whales which may be taken; prescribe open and closed seasons and areas for whaling; and prohibit the capture of suckling calves and female whales accompanied by calves. The compilation of catch reports and other statistical and biological records is also required. The

most recent Schedule was amended by the Commission at the 68th Annual Meeting in Portorož, Slovenia, October 2022.

Scoping = An open process agencies must conduct under the National Environmental Policy Act to determine the range and significance of the issues to be analyzed in depth in an Environmental Impact Statement.

Seabird breeding colonies = Sites at which seabirds congregate to breed (e.g., the numerous islands, rocks, and cliffs along the Washington coast).

Shoaling = Shallowing

Shrapnel = Fragments from an exploded projectile such as a bullet or bomb.

Stinker = As defined by regulations implementing the Whaling Convention Act, stinker refers to a dead, unclaimed whale found upon a beach, stranded in shallow water, or floating at sea.

Stinky whale = Whales that have a strong chemical smell and claimed to be inedible.

Stock = Under the Marine Mammal Protection Act, the term stock (or population stock) means a group of marine mammals of the same species or smaller taxa in a common spatial arrangement, that interbreed when mature.

Strike/Struck = As defined by the July 2012 Schedule to the International Convention for the Regulation of Whaling, strike means to penetrate with a weapon used for whaling.

Subsistence catches = A phrase defined by the 1981 *Ad Hoc* Technical Working Group (but not formally adopted by the International Whaling Convention) to mean catches of whales by aboriginal subsistence whaling operations.

Take = As defined by the July 2012 Schedule to the International Convention for the Regulation of Whaling, take means to flag, buoy or make fast to a whale catcher. As defined by the Marine Mammal Protection Act, take means to harass, hunt, capture, or kill, or attempt to harass, hunt, capture, or kill any marine mammal.

Thermocline = The depth where water temperature changes relatively rapidly and separates less dense, warmer waters from denser, colder waters.

Threatened species = As defined in the Endangered Species Act, a threatened species means any species which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range.

Toggle point = A specialized metal point that helps keep a harpoon from slipping out of a struck whale by means of a metal barb that actuates upon penetrating the whale's skin.

Training harpoon throws = A training harpoon throw is a harpoon throw made with a mock harpoon with blunted end incapable of penetrating a whale's skin.

Transfer station = A site used to temporarily store refuse prior to transporting it to the end point of disposal or treatment (e.g., a landfill).

Treaty of Neah Bay = The United States government and the Makah Tribe entered into the Treaty of Neah Bay on January 31, 1855. In addition to reserving the right of taking fish at all usual and accustomed grounds and stations, Article IV of the treaty secured the rights of whaling or sealing. The Treaty of Neah Bay is the only treaty between the United States and an Indian tribe that expressly provides for the right to hunt whales.

United States Coast Guard (USCG) = A branch of the United States Department of Homeland Security involved in maritime law, mariner assistance, and search and rescue in America's coasts, ports, and inland waterways as well as international waters with security and economic interests to the United States.

United States Fish and Wildlife Service (FWS) = A bureau within the United States Department of the Interior responsible for enforcing federal wildlife laws, protecting threatened and endangered species, managing migratory birds, restoring nationally significant fisheries, conserving and restoring wildlife habitat such as wetlands, and helping foreign governments with their international conservation efforts. The FWS manages 520 National Wildlife Refuges, including the Washington Islands National Wildlife Refuges.

Unsuccessful harpoon attempt = An unsuccessful harpoon attempt means the whale would not be struck (that is, would not have a harpoon embedded and would not show evidence of potentially lethal injury). This includes those associated with hunt training.

Usual and accustomed fishing grounds (U&A) = Areas in Washington where tribes have secured treaty rights to fish. The 1855 Treaty of Neah Bay secured these rights (including whaling and sealing rights) for the Makah tribe, and the tribe's U&A fishing grounds were adjudicated in *United States v. Washington*, 626 F.Supp. 1405, 1467 (W.D. Wash. 1985). The

boundaries of this U&A include United States waters in the western Strait of Juan de Fuca as well as open ocean areas of the Washington coast north of 48° 02'15" latitude and east of 125° 44'00" longitude.

Washington Islands National Wildlife Refuges = A complex of three National Wildlife Refuges (Flattery Rocks, Quillayute Needles, and Copalis) spanning over 100 miles of Washington's Pacific Coast. Refuge habitat consists of approximately 870 coastal rocks and reefs managed by the United States Fish and Wildlife Service primarily to protect seabird nesting.

Wasteful manner = As defined by NMFS regulations at 50 CFR 216.3: "[A]ny taking or method of taking which is likely to result in the killing of marine mammals beyond those needed for subsistence, subsistence uses, or for the making of authentic native articles of handicrafts and clothing, or which results in the waste of a substantial portion of the marine mammal and includes, without limitation, the employment of a method of taking which is not likely to assure the capture or killing of a marine mammal, or which is not immediately followed by a reasonable effort to retrieve the marine mammal."

Western North Pacific (WNP) gray whales = Gray whales that feed during the summer and fall in the Okhotsk Sea (primarily off northeast Sakhalin Island, Russia), some of which also feed off southeastern Kamchatka in the Bering Sea. WNP gray whales are considered a population stock under the MMPA, and the stock is designated as depleted. WNP gray whales are recognized as a distinct population segment (DPS) under the ESA and are designated as endangered.

Whale catcher = As defined by the Whaling Convention Act, a whale catcher is a vessel used for the purpose of hunting, killing, taking, towing, holding onto, or scouting for whales. The Makah tribe proposes to employ two types of whale catchers – a paddle-powered canoe(s) and a motorized chase boat.

Whaling captain = As defined by regulations implementing the Whaling Convention Act, a whaling captain or captain means any Native American who is authorized by a Native American whaling organization to be in charge of a vessel and whaling crew.

Whaling Convention Act (WCA) = A United States law that provides the framework for meeting United States obligations arising from the 1946 International Convention for the Regulation of Whaling. It provides for a United States Commissioner to the International Whaling Commission and authorizes the Secretary of State to present objections to that Commission's regulations. It establishes as unlawful whaling, transporting whales or selling whales, in violation of the Convention regulations. It sets up a whaling licensing framework,

with fines and imprisonment for violations. Enforcement is primarily the responsibility of the Secretary of Commerce.

Whaling crew = As defined by regulations implementing the Whaling Convention Act, a whaling crew means those Native Americans under the control of a captain. A Makah whaling crew consists of eight Makah tribal members; one serving as captain and the rest as a harpooner and paddlers.

1.0 PURPOSE AND NEED

1.1 Introduction

The National Marine Fisheries Service (NMFS) has prepared this Final Environmental Impact Statement (FEIS) for the Makah Indian Tribe's (Makah Tribe's or Tribe's) request for a waiver under the Marine Mammal Protection Act (MMPA) to resume ceremonial and subsistence harvest of eastern North Pacific (ENP) gray whales in their usual and accustomed fishing area (U&A). NMFS published a Draft Environmental Impact Statement (DEIS) on March 13, 2015 and received public comments through July 31, 2015 via email, mail, fax, and submissions to www.regulations.gov (Docket ID: NOAA-NMFS-2012-0104). We also held two public meetings in April 2015 to receive comments in person. We received more than 57,000 comments over the course of the 140-day comment period. Over 99% of comments were submitted as form letters.

In 2019, NMFS West Coast Region (WCR) issued a proposed waiver and proposed rule that would grant, in part, the Tribe's request and announced that NMFS would convene a hearing before an Administrative Law Judge (ALJ) on NMFS's proposals. During the hearing, held in November 2019, relevant information that became available after publication of the 2015 DEIS was presented, leading NMFS to determine that supplementing the DEIS was appropriate. We published a Supplemental DEIS on July 1, 2022 and received public comments until October 14, 2022. The public comment period was then briefly reopened from October 28 through November 3, 2022. We received 47 comments via email, mail, and submissions to www.regulations.gov (Docket ID: NOAA-NMFS-2012-0104). Commenters on the DEIS and SDEIS included state and federal entities, nonprofit organizations, and interested individuals from the United States and around the world. Responses to substantive comments received on the DEIS and SDEIS can be found in Appendix C.

This FEIS integrates the analyses presented in the DEIS and SDEIS, incorporating feedback from public comments and the best available science.

1.1.1 Summary of the Proposed Action

NMFS proposes[1] to issue a waiver and implementing regulations that would authorize the Makah Indian Tribe to resume a limited ceremonial and subsistence hunt of ENP gray whales

[1] This FEIS has been prepared pursuant to the Council on Environmental Quality's (CEQ) NEPA regulations (40 CFR 1500-1508) to evaluate the impacts of this proposed action and six reasonable alternatives, including a No-action Alternative. The use of the term "proposed" indicates that NMFS has yet to make a final decision, which allows this FEIS to inform that decision when it is made.

(*Eschrichtius robustus*) in the coastal portion of the Tribe's U&A, off the coast of Washington State.

The Tribe proposes to harvest of up to 20 whales over a 5-year period, with no more than five gray whales harvested in any single year. The Tribe's proposal (Alternative 2) also includes measures intended to limit the number of harpoon strikes in any year, avoid the intentional harvest of gray whales identified as part of the Pacific Coast Feeding Group (PCFG[2]), limit the annual harvest of PCFG whales based on the abundance of a subset of PCFG whales, ensure that the hunt is as humane as practicable, and protect public safety. This FEIS uses the term 'hunt' to include all activities associated with approaching, striking, killing, and landing whales, and the term 'harvest' to mean killing and landing a whale.

The 1855 Treaty of Neah Bay expressly secures the Makah Tribe's right to hunt whales. To exercise that right under the Ninth Circuit Court of Appeals decision in *Anderson v. Evans* (2004), however, the Makah must obtain authorization from NMFS. Two statutes govern any authorization: the MMPA (16 USC 1361 *et seq.*) and the Whaling Convention Act (WCA) (16 USC 916 *et seq.*). Specifically, to authorize Makah gray whale hunting, we, NMFS, must perform the following actions:

- Waive the moratorium prohibiting take of marine mammals under Section 101(a)(3)(A) of the MMPA.
- Promulgate regulations implementing the waiver and governing the hunts in accordance with Section 103 of the MMPA.
- Issue hunt permits to the Makah under Section 104 of the MMPA and the hunt regulations.
- Enter into a cooperative agreement with the Tribe for co-management of any gray whale hunt and publish any relevant aboriginal subsistence whaling quotas under the provisions of the WCA.

In February 2005, the Makah Tribe formally requested a waiver of the take moratorium under the MMPA to hunt gray whales (Appendix A). We published a notice of intent (NOI) to prepare an EIS in response to the Tribe's request (70 FR 49911, August 25, 2005). In January 2006, the Tribe asked us to take all necessary actions under whatever authorities we may deem applicable, and we announced that we would expand the scope of the EIS to include the WCA (71 FR 9781,

[2] In previous documents we referred to this feeding group as the Pacific Coast Feeding Aggregation or PCFA (NMFS 2008a). In this document we use PCFG, the term adopted by the International Whaling Commission (IWC) and more recent scientific assessments (IWC 2011a).

February 27, 2006). To assist in our MMPA and WCA determinations, we are preparing this FEIS under the National Environmental Policy Act (NEPA) as the lead agency reviewing this action (42 USC 4321 *et seq.*). See Subsection 1.2, Legal Framework, for more detail. The Tribe's proposal is described in Table 1-1. It is described in detail in Section 2, Alternatives.

Table 1-1. Summary of the Makah's Proposed Action

Species restrictions	Hunt ENP gray whales only.
Age/sex restrictions	Prohibit hunting of calves or whales accompanied by calves.
Number restrictions	Harvest up to 20 whales in a 5-year period, with a maximum of 5 whales harvested, 7 struck, and 3 struck and lost per calendar year. Reduce numbers of harvested, struck, and struck and lost whales as necessary in accordance with United States' obligations under the International Convention for the Regulation of Whaling (ICRW), or to prevent the ENP gray whale stock from falling below optimum sustainable population (OSP) levels under the MMPA. Cease hunting in any year if the number of harvested whales exceeds an allowable bycatch level based on matches in the National Marine Mammal Laboratory's photographic identification catalog for PCFG gray whales.[3]
Area restrictions	Hunt within the coastal portion of the Makah U&A, excluding the Strait of Juan de Fuca. Prohibit hunting within 200 yards (183 meters) of Tatoosh Island and White Rock during May to protect nesting seabirds.
Timing restrictions	Prohibit hunting from June 1 through November 30 during any calendar year to avoid intentional harvest of whales feeding off the coast of Washington during the summer feeding period.
Method of hunt restrictions	Hunt using traditional methods, except for the mandatory use of a .50 caliber rifle to kill the whale.
Use restrictions	Limit use of whale products to ceremonial and subsistence purposes. Prohibit the commercial sale or offer for sale of any whale products, except for sale or offer for sale of traditional handicrafts made from non-edible whale parts within the United States.

1.1.2 Makah Tribe's Proposed Hunt Location

The Makah Tribe proposes to resume gray whale hunting in the coastal portion of the Tribe's U&A, as adjudicated by the Western District Court of Washington in *United States v. Washington* (1974 and 1985). The Makah U&A includes marine waters off the northwest coast of Washington State and the western portion of the Strait of Juan de Fuca (Figure 1-1). The area proposed by the Tribe for hunting (Figure 1-1) is smaller than its adjudicated U&A because the Tribe proposes to exclude the Strait of Juan de Fuca to address concerns about public safety and the effects of hunts on gray whales in that area of its U&A.

Figure 1-1 also shows a larger action area, encompassing the entire Makah U&A and adjacent marine waters, as well as land areas with the potential to be affected by one or more of the action

[3] The National Marine Mammal Laboratory does not maintain a comprehensive PCFG catalog. Rather, a non-governmental organization, Cascadia Research Collective, maintains a database of photographically identified ENP gray whales (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements).

alternatives. (The entire range of the PCFG is shown in Figure 3-9, Spatial Scales Associated with the Action Area) The action area includes the following sites:

- Beaches where a gray whale may be landed and butchered.
- Rocks and islands of the Washington Islands National Wildlife Refuges within the waters of the Olympic Coast National Marine Sanctuary (OCNMS or Sanctuary), where sanctuary resources such as seabirds and hauled-out marine mammals might be affected.
- The Makah and Ozette Reservations and the community of Neah Bay (where many tribal members reside and public services are located).
- Other shoreline areas that provide physical or visual access to the Makah's U&A (e.g., vantage points provided by the coastal strip of the Olympic National Park).

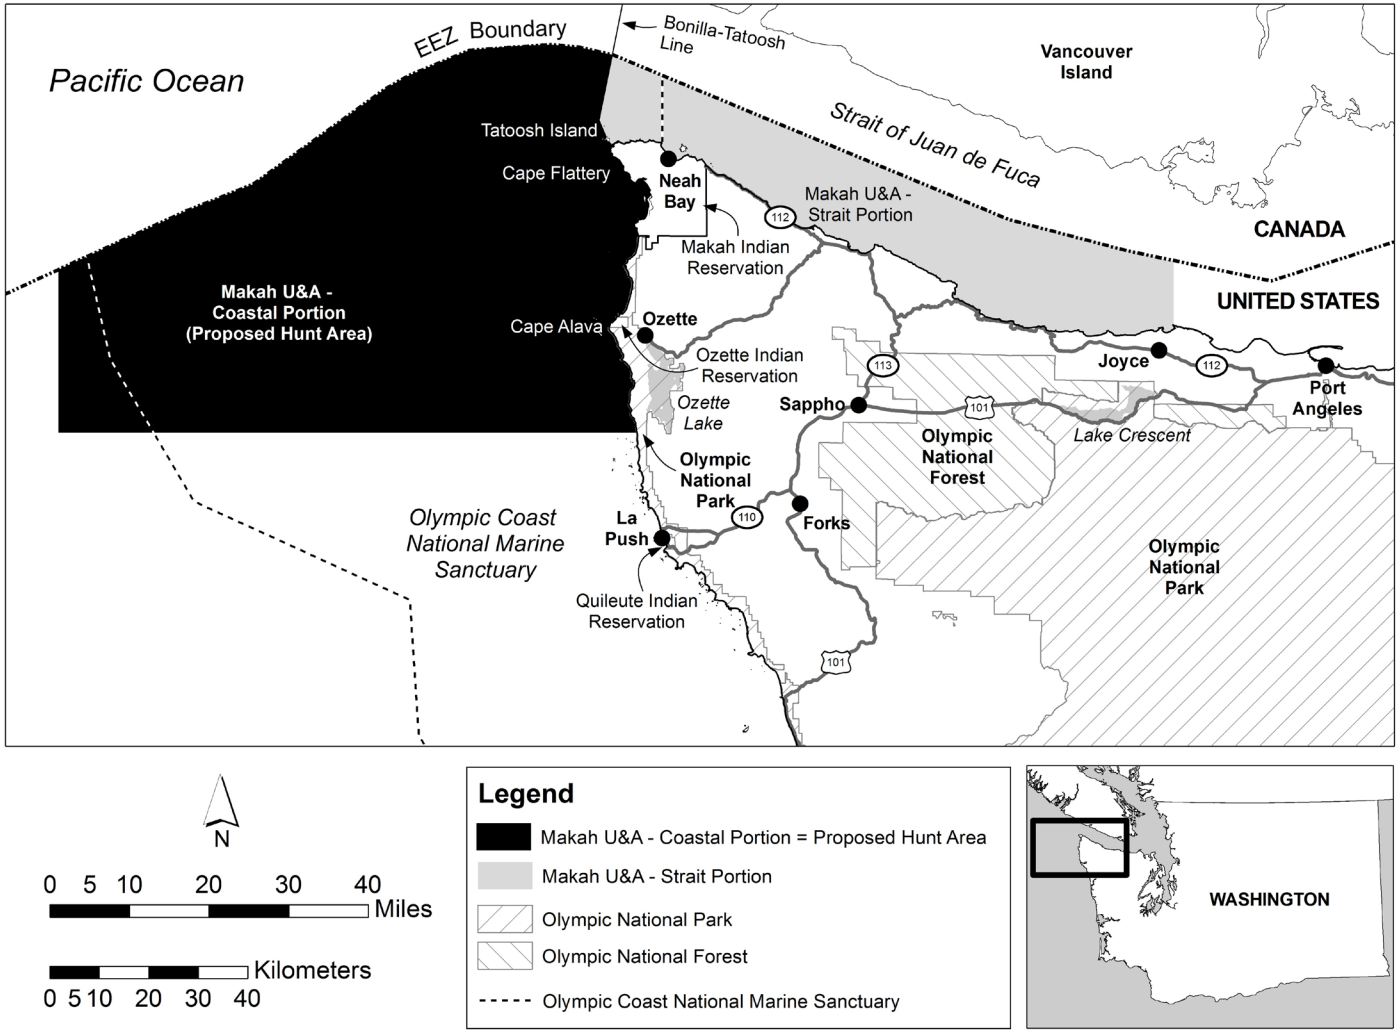

Figure 1-1. Action area.

1.1.3 Summary of Gray Whale Status

NMFS recognizes two stocks of gray whales in the north Pacific—the ENP stock and a western north Pacific (WNP) stock (Carretta et al. 2023; Weller et al. 2023). The ENP gray whale population migrates along the west coast of North America between Mexico and Alaska, and some whales are present year-round in the action area. The population sustained historical aboriginal hunting by natives in present-day Russia, Alaska, British Columbia, and Washington State for many centuries, but commercial whaling in the late 1800s and early 1900s decimated the population. Because of a suite of international and national protections (Subsection 3.4.3.1.3, Population Exploitation, Protection, and Status), the population recovered (Rugh et al. 2005). In 1994, ENP gray whales were delisted under the U.S. Endangered Species Act (ESA) (59 FR 31094, June 16, 1994). The current estimated population size is 14,526 animals (Eguchi et al. 2023). See Subsection 3.4, Gray Whales, for more information.

The distribution and migration patterns of gray whales in the WNP are less clear. The main feeding ground is in the Okhotsk Sea off the northeastern coast of Sakhalin Island, Russia, but some animals occur off southeastern Kamchatka and in other waters of the Okhotsk Sea (Subsection 3.4.3.2, Western North Pacific (WNP) Gray Whale). WNP whales were thought to all migrate south in autumn to wintering areas somewhere in the South China Sea, but recent information suggests that some animals feeding in the Okhotsk Sea migrate east, to coastal waters off the west coast of the United States and Baja Mexico during winter and may transit through the Makah U&A. WNP whales are listed as endangered under the ESA. In 2016, there were an estimated 290 animals (excluding calves) in the population with a 90% confidence interval of 271-311 animals (Cooke et al. 2018a). Subsection 3.4.3.2, Western North Pacific (WNP) Gray Whale, discusses the issues raised by the discovery of WNP migration to the west coast of the United States.

NMFS currently does not recognize the PCFG as a "population stock" as we interpret that term under the MMPA, but we have stated that the PCFG seems to be a distinct feeding aggregation and may warrant consideration as a stock in the future (Carretta et al. 2023). The International Whaling Commission (IWC) found it "plausible" that the PCFG may be a demographically distinct feeding group[4] (IWC 2011a) and has evaluated the United States' request for a quota for

[4] Although the IWC has not formally identified the PCFG as a stock, the IWC's Scientific Committee (IWC 2012a) noted that its implementation review of eastern North Pacific gray whales (with an emphasis on the PCFG) was "based on treating PCFG as a separate management stock" (which is not necessarily equivalent to a stock as defined under the MMPA).

the Makah Tribe against its impacts to PCFG whales (IWC 2013a; IWC 2018a) (Subsection 3.4.3.4.4, PCFG Status, Carrying Capacity, and Related Estimates). The current estimated population size of the PCFG is 212 animals (Harris et al. 2022). Subsection 3.4.3.4, Pacific Coast Feeding Group (PCFG) of Gray Whales, discusses the PCFG in greater detail.

1.1.4 Summary of Makah Tribe's Historic Whaling Tradition

The Makah's tradition of whale hunting dates back at least 1,500 years. Subsistence use of whale products from drift and stranded whales extends back another 750 years before that time, prior to development of hunting equipment and techniques (Wessen, G. as cited in Renker 2018). The gray whale was one of the major whale species the Makah hunted, likely because of its nearshore migration, slow swimming speed, and presence during the summer (Huelsbeck 1988). The fact that the Treaty of Neah Bay is the only treaty between the United States government and a Native American tribe that expressly protects the right to hunt whales suggests the historic importance of whaling to the Makah Tribe (*Anderson v. Evans* 2004). A combination of factors led to the suspension of Makah whaling in the 1920s (Subsection 3.10.3.4.2, Factors Responsible for Discontinuation of the Hunt).

On May 5, 1995, the Makah Tribe formally notified NMFS of its interest in re-establishing limited ceremonial and subsistence whale hunting (Makah Tribal Council 1995), approximately one year after NMFS removed the ENP gray whale from the list of endangered species under the ESA. Four years later, the Makah hunted and landed one gray whale. Judicial decisions have since prevented the Tribe from hunting gray whales until certain processes are completed. For more information on historic and contemporary Makah whaling, refer to Subsection 1.4.2, Summary of Recent Makah Whaling – 1998 through 2013, and Subsection 3.10, Ceremonial and Subsistence Resources.

1.2 Legal Framework

The following section describes the legal framework that will guide our decisions related to this project, including environmental review under NEPA, the Treaty of Neah Bay and the federal trust responsibility, species protection and conservation under the MMPA, and governance of aboriginal subsistence whaling quotas under the WCA.

1.2.1 National Environmental Policy Act

Congress enacted NEPA to create and carry out a national policy designed to encourage harmony between humankind and the environment. While NEPA neither compels particular results nor imposes substantive environmental duties upon federal agencies (*Robertson v. Methow Valley*

Citizens Council 1989), it does require that they follow certain procedures when making decisions about any proposed major federal actions that may affect the environment. These procedures ensure that an agency has the best possible information before it to make an informed decision regarding the environmental effects[5] of any proposed action. They also ensure full disclosure of any associated environmental risks to the public. Regulations promulgated by the Council on Environmental Quality (CEQ) (40 CFR 1500-1508) contain specific guidance for complying with NEPA.

This FEIS is being prepared under the 1978 CEQ NEPA regulations rather than the modified regulations promulgated by CEQ in 2020, with an effective date of September 14, 2020. NEPA reviews initiated prior to the effective date of the 2020 CEQ regulations may be conducted using the 1978 version of the regulations. This review began on May 21, 2012 (77 FR 29967), and the agency has decided to proceed under the 1978 regulations.

Under the 1978 CEQ regulations, federal agencies may prepare an environmental assessment (EA) to determine whether a proposed action may have a significant impact or effect on the quality of the human environment. Agencies must examine the context of the action and intensity of the effects to determine the significance of impacts. If information in an EA indicates that the environmental effects are not significant, the agency issues a finding of no significant impact (FONSI) to conclude the NEPA review. We issued FONSIs in two prior NEPA assessments of Makah whale hunting proposals. The history of those actions and ensuing court decisions is recounted in Subsection 1.4.3, Other Environmental Assessments and Court Decisions Informing this Action.

An EIS provides a detailed statement of the environmental impacts of the action, reasonable alternatives, and measures to mitigate adverse effects of the proposed actions. Although the MMPA and NEPA requirements overlap in some respects, the scope of NEPA goes beyond that of the MMPA by considering the impacts of the proposed major federal action on non-marine mammal resources, such as human health and cultural resources.

An EIS culminates in a Record of Decision (ROD). The ROD documents the alternative selected for implementation, may recommend further review, attaches any conditions that the agency may require, and summarizes the impacts expected to result from the alternative selected.

[5] The terms "effect" and "impact" are used interchangeably in this FEIS (consistent with Council on Environmental Quality regulations at 40 CFR 1508.8).

NMFS is the lead agency responsible for preparation of this FEIS. The Bureau of Indian Affairs is a cooperating agency as defined by CEQ.

1.2.2 Treaty of Neah Bay and the Federal Trust Responsibility

This Subsection provides a brief history of federal-tribal relations, a general legal description of the treaty rights of the Northwest tribes that evolved from that history, a more specific description of the Makah treaty right to hunt whales, the recent history of the Makah's efforts to use their treaty rights, and the current legal framework for implementation of those rights as defined in the Ninth Circuit Court's decision in *Anderson v. Evans* (2004).

Prior to 1871, to allow for the westward expansion of non-Indians, the United States government often entered into treaties with Indian tribes that typically provided for the surrender of large areas of land the Indians occupied. In exchange, the United States recognized permanent homelands (reservations) and sometimes explicitly or implicitly provided for off-reservation hunting, gathering, and fishing rights. Treaties with Indian tribes are the supreme law of the land and generally preempt state laws. Treaty language securing fishing and hunting rights is not a "grant of rights [from the federal government] to the Indians, but a grant of rights from them — a reservation of those not granted" (*United States v. Winans* 1905). In other words, the tribes retain rights not specifically surrendered to the United States (commonly referred to as reserved rights).

The scope of reserved Indian hunting, fishing, and gathering rights that have been recognized by the courts is sometimes very broad and depends on the language of the treaty or the known culture of the tribe at treaty time. Courts have developed rules for interpreting Indian treaties that recognize the communication difficulties between the tribes and treaty negotiators, the imbalance of power between the tribes and the United States, and the fact that the tribes are unlikely to have understood the legal ramifications of the exact wording of their treaties (Cohen 2005). Accordingly, courts liberally construe treaties, resolve ambiguities in the tribe's favor, and "interpret Indian treaties to give effect to the terms as the Indians themselves would have understood them" (*Minnesota v. Mille Lacs Band of Chippewa* 1999).

Twenty Indian tribes located in western Washington State have treaty-protected and adjudicated fishing rights in the Pacific Ocean, Strait of Juan de Fuca, and Puget Sound. The United States government and the Makah Tribe entered into the Treaty of Neah Bay on January 31, 1855, and the Senate consented to its ratification on March 8, 1859 (United States Statutes at Large, Volume 12, Page 939). In addition to reserving the right of taking fish at all usual and accustomed grounds and stations, Article IV of the treaty secured the rights of whaling or sealing. The Treaty

of Neah Bay is the only treaty between the United States and an Indian tribe that expressly provides for the right to hunt whales.[6]

1.2.2.1 The Stevens Treaties

"To extinguish the last group of conflicting claims to lands lying west of the Cascade mountains and north of the Columbia River, in what is now the State of Washington, the United States entered into a series of treaties with Indian Tribes in 1854 and 1855" (*Washington v. Washington State Commercial Passenger Fishing Vessel Association* 1979). These treaties are called the Stevens Treaties after Isaac Stevens, the Governor of Washington Territory, who was the United States negotiator. The Stevens Treaties settled the land claims and secured the hunting and fishing rights for numerous tribes, including the Makah Tribe. The promise that the Indian tribes would be guaranteed continued access to a variety of natural resources essential to their livelihood and way of life for future generations was essential for securing Indian consent to the treaties with the United States (*United States v. Washington* 1974). The scope of reserved Indian hunting, fishing, trapping, and gathering rights that courts have recognized depends on the language of the treaty and the circumstances surrounding the treaty negotiations.

1.2.2.2 Scope of the Fishing Right under the Stevens Treaties

The fishing clauses of the Stevens Treaties have been at the center of litigation for more than 100 years, including state attempts to limit the exercise of treaty fishing rights. *United States v. Washington* (1974), commonly referred to as the "Boldt" decision, defined the scope of these treaty rights to fish. The court held that state regulation of treaty fishing was authorized only if reasonable and necessary for conservation. In affirming this decision the Supreme Court also interpreted the Stevens Treaties to secure 50 percent of the harvestable surplus of fish passing through their "usual and accustomed grounds and stations" (*United States v. Washington* 1974) to the tribes, unless their moderate living needs could be met by a lesser amount (*Washington v. Washington State Commercial Passenger Fishing Vessel Association* 1979). The Treaty of Neah Bay was one of the Stevens Treaties reviewed in the *United States v. Washington* (1974) litigation. Although the court's focus in that proceeding was to address the appropriate exercise of the Tribe's fishing rights, in reviewing the treaty, the court noted the following:

[6] Article 4 of the 1855 Treaty with the Makah (see Appendix A) states: "The right of taking fish and whaling and sealing at usual and accustomed grounds and stations is further secured to said Indians in common with all citizens of the United States, and of erecting temporary houses for the purpose of curing, together with the privilege of hunting and gathering roots and berries on open and unclaimed lands: Provided, however, That they shall not take shell-fish from any beds staked or cultivated by citizens."

> [t]he treaty commissioners were aware of the commercial nature and value of the Makah maritime economy and promised the Makah that the government would assist them in developing their maritime industry. Governor Stevens found the Makah not much concerned about their land . . . but greatly concerned about their marine hunting and fishing rights. Much of the official record of the treaty negotiations deals with this. Stevens found it necessary to reassure the Makah that the government did not intend to stop them from marine hunting and fishing but in fact would help them develop these pursuits (*United States v. Washington* 1974).

Additionally, the court noted the following:

> [i]n aboriginal times the Makah enjoyed a high standard of living as a result of their marine resources and extensive marine trade. . . . The Makah not only sustained a Northwest Coast culture, but also were wealthy and powerful as contrasted with most of their neighbors (*United States v. Washington* 1974).

The Court of Appeals for the Ninth Circuit similarly noted that the specific reservation of the right to whale in the Treaty of Neah Bay "suggests the historic importance of whaling to the Makah Tribe" (*Anderson v. Evans* 2004). The Makah U&A for fishing was defined in a later sub-proceeding under *United States v. Washington* (1985). The Tribe's usual and accustomed whaling and sealing grounds have not been adjudicated.

1.2.2.3 Limitations on the Exercise of Treaty Rights

Treaty rights are not unbounded. The United States Supreme Court has held that the United States Congress has full power over Indian lands and Indian tribes and can abrogate federal Indian treaties (*Lone Wolf v. Hitchcock* 1903) unilaterally, though doing so may implicate Fifth Amendment taking by the federal government and the need for federal compensation (*Menominee Indian Tribe v. United States* 1968; *Hynes v. Grimes Packing Company* 1949; *United States v. Shoshone Tribe of Indians* 1938). The courts will not lightly find that treaty rights have been abrogated (*Menominee Indian Tribe v. United States 1968*). Generally, states cannot regulate treaty hunting and fishing activities (*Menominee Tribe v. United States* 1968). However, the states of Washington and Oregon have some ability to limit the exercise of Indian treaty rights for conservation purposes where such regulation is necessary to sustain the species.

1.2.2.3.1 State Regulation

In the Pacific Northwest, a significant body of law has developed over the last 40 years in response to state attempts to impose regulations that effectively prevented tribal fishermen from taking fish at their usual and accustomed places. In the 1970s, the United States brought litigation on behalf of the Stevens Treaty tribes against the states of Washington and Oregon to establish the treaty right guarantees of access to the usual and accustomed tribal fishing places and to an equitable share of the harvestable fish. The courts held that states could not qualify the treaty

right. In a series of decisions responsive to growing concerns regarding the continued viability of the natural resources in question, however, the Supreme Court affirmed the states' police power to regulate tribal fisheries for conservation purposes where such regulation is necessary to sustain the species. The court stated the following:

> [t]he right to take fish at all usual and accustomed places may, of course not be qualified by the State . . . [b]ut the manner of fishing, the size of the take, the restriction of commercial fishing, and the like may be regulated by the State in the interest of conservation, provided the regulation meets appropriate standards and does not discriminate against Indians (*Puyallup Tribe v. Washington Department of Game* 1968).

In reviewing state conservation regulations, the courts use the conservation necessity principle to ensure that the regulation does not discriminate against the treaty tribe's reserved right to fish, is reasonable and necessary to preserve and maintain the resource, and the conservation required cannot be achieved by restriction of fishing by non-treaty fishermen or by other less restrictive means or methods (*United States v. Washington* 1974). As defined in these court decisions, conservation is a term of art and has been defined alternatively as "those measures which are reasonable and necessary to the perpetuation of a particular run or species of fish" (*United States v. Washington* 1974) and as "preserving a 'reasonable margin of safety' between an existing level of [salmon] stocks and the imminence of extinction…" (*United States v. Oregon* 1983). Although the courts have imposed limits on the nature of state regulation of treaty fishing, they have also held that "neither the treaty Indians nor the state on behalf of its citizens may permit the subject matter of these treaties to be destroyed" (*United States v. Washington* 1974).

1.2.2.3.2 Federal Regulation

Congress exercises plenary power in the field of Indian affairs. As part of this authority, the United States Supreme Court has consistently held that Congress, through the enactment of laws, has the authority to abrogate or modify the exercise of Indian treaty rights. This includes congressional power to abrogate or modify treaty rights through statutes that address conservation of natural resources. To find abrogation, however, the Supreme Court has required "clear evidence that Congress actually considered the conflict between the intended action on the one hand and Indian treaty rights on the other, and chose to resolve the conflict by abrogating the treaty" (*United States v. Dion* 1986).

In *Anderson v. Evans* (2004), the court found that the MMPA applies to the Makah Tribe and constrains its treaty right to harvest whales to ensure that "the conservation goals of the MMPA are effectuated." In holding that the MMPA applied to the Tribe, the court stated that "[w]e need not and do not decide whether the Tribe's whaling rights have been abrogated by the MMPA."

The court also noted that "[u]nlike other persons applying for a permit or waiver under the MMPA, the Tribe may urge a treaty right to be considered" during review of the Tribe's request (*Anderson v. Evans* 2004).

1.2.2.4 The Federal Trust Responsibility

The United States and Indian tribes have a unique relationship. From the formation of the United States to the present, federal law has recognized Indian tribes as independent political entities with authority over their members and territory (*Worcester v. Georgia* 1832). The United States Constitution provides Congress with the authority to regulate commerce "among the several states, and with the Indian Tribes" (United States Constitution, Article I, Section 8, clause 3). This power to regulate commerce with Indian tribes includes the exclusive authority to enter into treaties and agreements with Indian tribes regarding their rights to aboriginal lands. Central to such treaties and agreements in the Pacific Northwest is the reservation of Indian hunting, gathering, and fishing rights both on and off the reservation. These express and implied reservations preserve the inherent rights of the tribe that have not been limited or abrogated by treaty or federal legislation.

The federal government has a trust responsibility to protect the treaty hunting, fishing, and gathering rights of Indian tribes. As described by the Supreme Court, "under a humane and self-imposed policy which found expression in many acts of Congress and numerous decisions of this Court, [the United States] has charged itself with moral obligations of the highest responsibility and trust" (*Seminole Nation v. United States* 1942). This unique relationship provides the basis for legislation, treaties, and executive orders that grant unique rights or privileges to Native Americans (*Morton v. Mancari* 1974). The trust responsibility requires federal agencies to carry out their activities in a manner that is protective of these express rights *(Gros Ventre Tribe v. United States* 2006). The Ninth Circuit Court of Appeals has held, however, that "unless there is a specific duty that has been placed on the government with respect to Indians, [the government's general trust obligation] is discharged by [the government's] compliance with general regulations and statutes not specifically aimed at protecting Indian tribes" (*Gros Ventre Tribe v. United States* 2006, citing *Morongo Band of Mission Indians v. FAA* 1998; *United States v. Jicarilla Apache Nation* 2011)).

Executive Order 13175 (implemented by Department of Commerce Administrative Order 218-8) affirms the trust responsibility of the United States and directs agencies to "establish regular and meaningful consultation and collaboration with tribal officials," and respect tribal sovereignty when developing "Federal policies that have tribal implications." (see the Presidential

Memorandum from November 5, 2009 and January 26, 2021 reaffirming EO 13175). This policy is also reflected in the Department of Commerce "Tribal Consultation and Coordination Policy" (78 FR 33331, June 4, 2013). NMFS, as an agent of the federal government, has a trust responsibility to Indian tribes. For example, see Secretarial Order 3206 and NOAA's Policy on Government-to-Government Consultation with Federally Recognized Indian Tribes and Alaska Native Corporations (NOAA Administrative Order 218-8, June 15, 2014 and reviewed on December 19, 2018).

1.2.3 Marine Mammal Protection Act

1.2.3.1 Section 2 – Findings and Declaration of Policy

Congress enacted the MMPA to protect and conserve marine mammals and their habitats. Section 2 of the MMPA contains the general purposes and policies of the Act, including congressional findings (16 USC 1361). Congress was concerned that certain marine mammal species and population stocks were in danger of extinction or depletion, and it intended to establish protections to encourage development of those stocks to the greatest extent feasible, commensurate with sound policies of resource management. Therefore, Congress specified that the primary objective of marine resource management under the MMPA is to maintain the health and stability of the marine ecosystem. Section 2 indicates that stocks should not be permitted to diminish beyond the point at which they cease to be a significant functioning element of the ecosystem, and they should not be permitted to diminish below their optimum sustainable population (OSP) level (Subsection 3.4.2.1, Marine Mammal Protection Act Management).

1.2.3.2 Section 101(a) – Take Moratorium

To achieve the general purposes and policies of Section 2 of the MMPA, Congress established a moratorium on the taking and importing of marine mammals in Section 101(a) (16 USC 1371(a)). Under the MMPA, 'take' means to "harass, hunt, capture, or kill, or attempt to harass, hunt, capture, or kill any marine mammal" (16 USC 1362(13)). 'Harassment' is defined as follows:

> . . . any act of pursuit, torment, or annoyance which (1) has the potential to injure a marine mammal or marine mammal stock in the wild [Level A Harassment]; or (2) has the potential to disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering [Level B Harassment] (16 USC 1362(18)(A)).

This moratorium is not absolute. Statutory exceptions allow marine mammals to be taken for scientific or educational purposes and to be taken incidentally in the course of commercial fishing. A statutory exemption allows take of marine mammals by Alaska Natives for subsistence

purposes or to create and sell authentic native articles of handicraft and clothing. The agency may also waive the take moratorium under Section 101(a)(3).

1.2.3.3 Section 101(a)(3)(A) – Waiver of the Take Moratorium

Section 101(a)(3)(A) authorizes and directs the Secretary of Commerce "from time to time" to "determine when, to what extent, if at all, and by what means, it is compatible" with the MMPA "to waive the Section 101(a) take moratorium" (16 USC 1371(a)(3)(A)). NMFS considers whether to waive the take moratorium on a case-by-case basis, either when a waiver appears appropriate or when a specific proposal is presented. NMFS waives the moratorium only with respect to a particular species or stock and then only to the extent provided in the waiver (Bean 1983). As described in Subsection 3.17.3.1, Waivers of the MMPA Take Moratorium, the waiver process involves a number of steps, is seldom requested, and has not been undertaken many times.

The following discussion responds to past public comments requesting that we summarize the MMPA procedures for waiving the take moratorium and issuing permits. The primary steps of the MMPA waiver process include:

1. Initial waiver determination and development of proposed implementing regulations.
2. Formal rulemaking on the record (including a hearing before a presiding official, such as an administrative law judge).
3. Final waiver determination (including final regulations).
4. Permit application and processing.

Preparation of this FEIS is one step in a full evaluation of the Makah's request to hunt gray whales and will aid future decisions related to the MMPA as well as under the WCA (discussed in Subsection 1.2.4, Whaling Convention Act).

1.2.3.3.1 Step 1 ─ Initial Waiver Determination

NMFS' West Coast Regional Administrator was the delegated authority in this case to make the initial waiver determination (NMFS 2005a). Section 101(a)(3)(A) of the MMPA contains provisions related to the waiver determination. Any waiver determination must fulfill the following criteria:

1. Be based on the best scientific evidence available.
2. Be made in consultation with the Marine Mammal Commission.

3. Have due regard to the distribution, abundance, breeding habits, and times and lines of migratory movements of the marine mammal stock in question for take.
4. Find that the taking is in accord with sound principles of resource protection and conservation as provided in the purposes and policies of the MMPA (which include maintaining marine mammals as a significant functioning element in the ecosystem of which they are a part, maintaining the health and stability of the marine ecosystem, and obtaining an optimum sustainable population keeping in mind the carrying capacity of the habitat).

Based on these Section 101(a)(3)(A) criteria, the Regional Administrator made an initial determination to waive the take moratorium and proposed regulations to govern any take under Section 103 (84 FR 13604, April 5, 2019). Section 103(a) specifies that regulations must be "necessary and appropriate to insure that such taking will not be to the disadvantage of those species and population stock and will be consistent with the purposes and policies [of section 2 of the MMPA]" (16 USC 1373(a)).

Section 103(b) requires the agency must give full consideration to all factors that may affect the extent to which the stock may be taken, including but not limited to:

- Existing and future levels of marine mammal species and population stocks
- Existing international treaty and agreement obligations of the United States
- The marine ecosystem and related environmental considerations
- The conservation, development, and utilization of fishery resources
- The economic and technological feasibility of implementation

Section 103(c) of the MMPA lists allowable restrictions that regulations may include for takes of marine mammals such as the number, age, size, and sex of animals taken, as well as the season, manner, location, and fishing techniques that may be used (for marine mammals caught in fishing gear incidental to fishing activities). Any regulations would be subject to periodic review and modification to carry out the purposes of the MMPA (16 USC 1373(e)).

1.2.3.3.2 Step 2 – Formal Rulemaking on the Record

A decision to waive the take moratorium must be made after opportunity for an agency hearing pursuant to the formal rulemaking process detailed in agency regulations at 50 CFR Part 228. Under these provisions, in early 2019 NMFS appointed an ALJ to preside over the hearing (presiding official) and published a Notice of Hearing in the Federal Register regarding the proposed waiver and proposed regulations (84 FR 13639, April 5, 2019).

The Notice stated the place and date for both a pre-hearing conference and the hearing itself, including details for how and when to submit direct (written) testimony on the proposed waiver and proposed regulations, and how and when to submit a notice of intent to participate in the pre-hearing conference and hearing. It also identified issues of fact that might be involved in the hearing and explained that NMFS's initial direct testimony in support of the proposed waiver and regulations was available on the ALJ's hearing website at: https://www.uscg.mil/Resources/Administrative-Law-Judges/Decisions/ALJ-Decisions-2016/NOAA-Formal-Rulemaking-Makah-Tribe/.

Along with the Notice of Hearing, we also published a proposed rule to govern hunts (84 FR 13639, April 5, 2019), which addressed, among other topics:

- A summary of the statements required by Section 103(d) of the MMPA, including the following:
  - Estimated existing levels of gray whales;
  - Expected impact of the proposed regulations on the OSP of any gray whale stock;
  - Description of the evidence before the Regional Administrator upon which the proposed regulations would be based;
  - Any studies made by or for the Regional Administrator or any recommendations made by or for the agency or the Marine Mammal Commission that relate to the establishment of the proposed regulations;
- Written advice received from the Marine Mammal Commission.

The hearing in front of ALJ George J. Jordan occurred from November 14-21, 2019. The hearing was a trial-type proceeding where the ALJ reviewed the proposed waiver and regulations in addition to written and oral testimony. Six parties—the Makah Tribe, NMFS, the Marine Mammal Commission, Sea Shepherd Legal, the Peninsula Citizens for the Protection of Whales, and the Animal Welfare Institute—presented evidence and expert testimony for the ALJ's consideration. The full hearing record and transcript were made available for public inspection at https://www.uscg.mil/Resources/Administrative-Law-Judges/Decisions/ALJ-Decisions-2016/NOAA-Formal-Rulemaking-Makah-Tribe/. Following the hearing, NMFS published a notice and request for public comments on the hearing record regarding the proposed waiver and proposed regulations (85 FR 5196, January 29, 2020). On September 23, 2021, the ALJ issued a recommended decision, which found that the best scientific evidence available supports a waiver of the MMPA's take moratorium to allow the Makah Tribe to engage in a limited hunt for ENP

gray whales and that the proposed regulations, with recommended modifications, are adequate to implement the waiver.

1.2.3.3.3 Step 3 ─ Final Waiver Determination

Once the NMFS Assistant Administrator received the presiding official's recommended decision, the agency published notice of availability in the Federal Register on September 29, 2021 (86 FR 53949), sent copies of the recommended decision to all parties, and provided a 20-day written comment period, which was extended by 25 days (86 FR 57639, October 18, 2021). At the close of the comment period and upon completion of environmental compliance with other statutes (see Subsection 1.2, Legal Framework) and of any necessary evaluations under the ESA, the NMFS Assistant Administrator will make a final decision on the proposed waiver and proposed regulations. The final decision may affirm, modify, or set aside (in whole or part) the recommended findings, conclusions, and decision of the presiding official. We will publish the final decision in the Federal Register. If the NMFS Assistant Administrator issues the waiver, we would promulgate final implementing regulations with the decision.

1.2.3.3.4 Step 4 ─ Permit Authorizing Take

Section 104 of the MMPA governs our issuance of permits authorizing the take of marine mammals. We must publish notice of each application for a permit in the Federal Register and invite the submission of written data or views from interested parties with respect to the taking proposed in the application within 30 days after the date of the notice (16 USC 1374(d)(2)). The applicant for the permit must demonstrate that the taking of any marine mammal under such permit will be consistent with the purposes and policies of the MMPA and the applicable regulations established under MMPA Section 103.

If an interested party requests a hearing in connection with the permit within 30 days of publication of the notice, we may afford an opportunity for a hearing within 60 days of the date of the published notice (16 USC 1374(d)(3)). Any applicant for a permit or any party opposed to a permit may obtain judicial review of the agency's terms and conditions included the permit, or of the agency's refusal to issue a permit (16 USC 1374(d)(4)). A permit issued under MMPA Section 104 (16 USC 1374(b)) must be consistent with applicable regulations and must specify the following:

- The number and kinds of animals authorized to be taken;
- The location and manner (which we must determine to be humane) in which they may be taken;

- The period during which the permit is valid;
- Other terms or conditions that we deem appropriate.

The MMPA defines 'humane' as "that method of taking which involves the least possible degree of pain and suffering practicable to the mammal involved" (16 USC 1362(4)).

1.2.3.4 Application of the MMPA to Makah Whaling

The Court of Appeals for the Ninth Circuit has twice reviewed NMFS proposals to authorize the Tribe to exercise the treaty right to hunt gray whales. In the most recent decision, the court held that the permit and waiver provisions of the MMPA must be satisfied before we can authorize a hunt (*Anderson v. Evans* 2004). Relying on the "principles embedded in the Treaty of Neah Bay, itself," the court framed the issue for decision as "whether restraint on the Tribe's whaling pursuant to treaty rights is necessary to effectuate the conservation purpose of the MMPA" (*Anderson v. Evans* 2004). The court defined the conservation purpose of the MMPA as "to ensure that marine mammals continue to be significant functioning element[s] in the ecosystem" and not "diminish below their optimum sustainable population" (*Anderson v. Evans* 2004).

Specifically, the court stated:

> . . . [t]o carry out these conservation objectives, the MMPA implements a sweeping moratorium in combination with a permitting process to ensure that the taking of marine mammals is specifically authorized and systematically reviewed. For example, the MMPA requires that the administering agency consider "distribution, abundance, breeding habits, and times and lines of migratory movements of such marine mammals" when deciding the appropriateness of waiving requirements under the MMPA, 16 USC Section 1371 (a)(3)(A). And, when certain permits are issued, the permit may be suspended if the taking results in "more than a negligible impact on the species or stock concerned" (16 USC Section 1371 (a)(5)(B)(ii)). One need only review Congress's carefully selected language to realize that Congress's concern was not merely with survival of marine mammals, though that is of inestimable importance, but more broadly with ensuring that these mammals maintain an "optimum sustainable population" and remain "significant functioning elements in the ecosystem." The MMPA's requirements for taking are specifically designed to promote such objectives. Without subjecting the tribe's whaling to review under the MMPA, there is no assurance that the takes by the tribe of gray whales, including both those killed and those harassed without success, will not threaten the role of gray whales as functioning elements of the marine ecosystem, and thus no assurance that the purpose of the MMPA will be effectuated (*Anderson v. Evans* 2004).

Additionally, the court stated:

> . . . [h]ere the purpose of the MMPA is not limited to species preservation. Whether the Tribe's whaling will damage the delicate balance of the gray whales in the marine ecosystem is a question that must be asked long before we reach the desperate point

> where we face a reactive scramble for species preservation (*Anderson v. Evans* 2004).

The court found these principles "embedded in the Treaty of Neah Bay" and Supreme Court precedents and stated:

> . . . [j]ust as treaty fisherman are not permitted to totally frustrate . . . the rights of non-Indian citizens of Washington to fish . . . the Makah cannot consistent with the plain terms of the treaty, hunt whales without regard to processes in place and designed to advance conservation values by preserving marine mammals or to engage in whale watching, scientific study, and other non-consumptive uses. (*Anderson v. Evans* 2004).

The court noted that in requiring compliance with the MMPA, "we do not purport to address what limitations on the scope of a permit, if any is issued, would be appropriate." Further, in recognition of the Tribe's unique status the court stated, "[u]nlike other persons applying for a permit or waiver under the MMPA, the Tribe may urge a treaty right to be considered in the NMFS's review of an application by the Tribe under the MMPA" (*Anderson v. Evans* 2004). The Makah Tribe has informed us that it believes that the Treaty of Neah Bay bars us from denying the Tribe's request for a waiver where tribal whaling can be accomplished in a manner consistent with the conservation purposes of the MMPA. According to the Tribe, this means that the whaling would not cause the ENP stock of gray whales to fall below its optimum sustainable population or to cease to be a significant functioning element of the marine ecosystem (Makah Tribe 2005a; Makah Tribe 2006a). Furthermore, the Tribe contends that we may not impose restrictions on the exercise of the Tribe's whaling right, beyond those the Tribe itself proposed in its MMPA waiver and permit request, unless we show such restriction to be necessary to achieve the MMPA's conservation purpose (Makah Tribe 2005a; Makah Tribe 2006a).

1.2.4 Whaling Convention Act

Congress enacted the WCA to implement the domestic obligations of the United States government under the International Convention for the Regulation of Whaling (ICRW). This FEIS analyzes NMFS' domestic authority and responsibilities under the WCA, but it does not analyze the position of the United States as a political body in the international arena. The FEIS does, however, describe international whaling governance under the ICRW to provide context for the WCA statutory and regulatory framework and particularly to address issues raised in past public comments.

1.2.4.1 International Whaling Governance under the ICRW

The ICRW is an international treaty signed on December 2, 1946, to "provide for the proper conservation of whale stocks and thus make possible the orderly development of the whaling

industry" (ICRW, Dec. 2, 1946, 161 United Nations Treaty Series 72). The United States was an original signatory to the ICRW in 1946. The ICRW established the IWC. Below we describe the functions and operating procedures of the IWC, the IWC's moratorium on commercial whaling, aboriginal subsistence whaling under the IWC, and the United States' preparation for the IWC.

1.2.4.1.1 Functions and Operating Procedures of the IWC

The IWC is an international organization whose membership consists of one commissioner from each contracting government. Under Article V.1 of the ICRW, the IWC's charge is to adopt regulations for the conservation and utilization of whale resources by periodically amending the Schedule, a document that is an integral part of the ICRW. IWC regulations adopted in the Schedule may do the following:

- Designate protected and unprotected species;
- Open and close seasons and waters;
- Implement limits on the size of whales taken, and on the time, method, and intensity of whaling;
- Specify gear, methods of measurement, catch returns and other statistical and biological records, and methods of inspection for the stocks of large cetaceans under IWC jurisdiction (i.e., baleen and sperm whales).

The IWC seeks to reach consensus on Schedule amendments. When consensus is not possible, a three-fourths majority of all who voted may amend the Schedule (each contracting government has one vote).

Article V.2(b) of the ICRW specifies that amendments to the Schedule must be based on scientific findings. The IWC established the Scientific Committee, consisting of approximately 200 of the world's leading whale biologists, to provide advice on the status of whale stocks. The Scientific Committee meets annually and may also call special meetings as needed to address particular subjects during the year.

Article V.3 of the ICRW governs the procedure for amending the Schedule, including application of IWC whaling regulations. In general, amendments to the Schedule are effective 90 days after the IWC notifies each contracting government of the amendment, unless a contracting government objects. If an objection occurs, the objector and other contracting governments have a certain period to present objections to the IWC. After that period expires, the amendment is effective with respect to all contracting governments that have not presented objections, but it is not effective for the objector(s) until the objection is withdrawn. A contracting government may use this procedure when it considers its national interests or sovereignty unduly affected.

1.2.4.1.2 IWC Commercial Whaling Moratorium

The IWC initially focused on regulation of the commercial whaling industry. In 1982, the IWC approved a moratorium on all commercial whaling in paragraph 10(e) of the Schedule, effectively expanding the 1937 ban on commercial harvest of gray whales and right whales to all large whale species. The commercial whaling moratorium is still in place for all non-objecting parties. Iceland lodged a reservation and Norway and the Russian Federation lodged objections to paragraph 10(e) that are currently effective, so the moratorium does not apply to those countries, though the Russian Federation does not exercise their objection. The United States was a party to the 1937 agreement that banned commercial whaling of gray whales. The United States was also instrumental in urging the IWC to adopt the 1982 moratorium on commercial whaling of all species (commercial whaling of all species in the United States has been prohibited nationally since 1971). The United States remains opposed to commercial whaling.

Paragraph 10(e) also states that the commercial whaling moratorium "will be kept under review, based upon the best scientific advice," and that "the [IWC] will undertake a comprehensive assessment of the effects of [the commercial whaling moratorium] on whale stocks and consider modification of this provision and the establishment of other catch limits" (IWC 2022a). The IWC has been developing a revised management scheme (a management plan for commercial whaling), but has made little progress on its adoption. There is active debate at the IWC about the sustainability of whale stocks, the appropriateness of maintaining the ban on all commercial whaling, and the type and level of supervision of commercial whaling should it resume.

1.2.4.1.3 IWC Aboriginal Subsistence Whaling

The IWC recognizes a distinction between whaling for commercial purposes and whaling by aborigines for ceremonial and subsistence purposes — aboriginal exceptions were incorporated into predecessor treaties to the ICRW and have been a part of the whaling regime under the ICRW since the time of the first Schedule (as used in this FEIS, the term 'aborigines' refers to indigenous people). The IWC governs aboriginal subsistence whaling (ASW) by setting catch limits for certain whale stocks in the Schedule after considering requests from contracting governments and/or after consulting with the Scientific Committee. Contracting governments request catch limits on behalf of aborigines in their respective nations, and previously were required to submit a proposal to the IWC based on cultural and nutritional needs documented in a needs statement. An expert workshop convened by the IWC in 2015 concluded that the cultural and nutritional needs of these communities had been well-documented and that it was no longer appropriate for the Commission to continue to require these "need statements" as a condition for

receiving a quota (IWC 2015). The IWC has now posted to its website descriptions of the aboriginal subsistence whaling hunts carried out by contracting governments that outline information on recent catches, hunting methods, relevant international and national regulations, and the cultural and nutritional significance of the hunt, as well as the most recent advice of the Scientific Committee on the status of the relevant stocks and the catch or strike limit requested (IWC 2015). General principles governing ASW are contained in paragraph 13(a) of the Schedule. Section 13(a)(4) prohibits "strik[ing], tak[ing] or kill[ing] calves or any whale accompanied by a calf," and 13(a)(5) requires that "all aboriginal whaling shall be conducted under national legislation that accords with [paragraph 13 of the Schedule]" (IWC 2022a).

The current catch limits were set in a 2018 Amendment to the Schedule (IWC 2018b) and cover 2019 through 2025 in a one-time 7-year quota (IWC 2022a). Starting in 2026, catch limits will be allocated in six-year blocks whereby catch limits will be reviewed in the year prior to their expiration at the biennial Commission meeting with scientific advice from the Scientific Committee. Paragraph 13(b)(2) of the current Schedule (IWC 2018a; 2022a) sets a landing limit of 980 ENP gray whales and a strike limit of 140 in any year of the quota period to "aborigines or a Contracting Government on behalf of aborigines . . . only when the meat and products of such whales are to be used exclusively for local consumption by the aborigines." The 2018 Amendment also allows for unused strikes to be carried forward and added to the strike limit of subsequent years, provided that no more than 50% of the annual strike limit is added to any one year. Beginning in 2026, the catch limits set in 2018 will automatically carry forward for six more years provided that the Scientific Committee advises that these catch limits will not harm the stocks, the ASW country relying on the stocks does not request a change in its respective catch limits, and the IWC determines that the ASW countries have complied with the approved timeline of reporting requirements set for them and that the information provided represents a status quo continuation of the hunt.

The IWC set the ENP gray whale catch limit in response to a joint request from the United States, the Russian Federation, Denmark on behalf of Greenland, and St. Vincent and the Grenadines. The one-time 7-year (2019-2025) ENP gray whale catch limit is allocated through a bilateral agreement between the United States and the Russian Federation as five strikes per year for the Makah Tribe and 135 strikes per year for the Chukotka Natives (i.e. Fominykh and Wulff 2023).

Due to some controversy and negotiations about appropriate catch limits for Alaska Natives' bowhead hunts in 1977 and 1978, a meeting of experts on wildlife science, nutrition, and cultural anthropology convened in Seattle from February 5 to 9, 1979 (the experts in cultural

anthropology convened for this meeting were known as the Cultural Anthropology Panel). Their charge was to examine the Alaska Natives' bowhead harvest, provide data, and develop a report for an IWC Technical Committee examining the aboriginal subsistence whaling processes. The Cultural Anthropology Panel at that meeting developed a working definition of subsistence use (IWC 1979a), a term not defined in the ICRW or the Schedule (but adopted 25 years later by a consensus of the delegates to the 2004 annual meeting of the IWC; Subsection 1.2.4.1.3, IWC Aboriginal Subsistence Whaling):

- The personal consumption of whale products for food, fuel, shelter, clothing, tools, or transportation by participants in the whale harvest.
- The barter, trade, or sharing of whale products in their harvested form with relatives of the participants in the harvest, with others in the local community, or with persons in locations other than the local community with whom local residents share familial, social, cultural, or economic ties. A generalized currency is involved in this barter and trade, but the predominant portion of the products from each whale are ordinarily directly consumed or utilized in their harvested form within the local community.
- The making and selling of handicraft articles from whale products when the whale is harvested for the purposes defined in (1) and (2) above.

A working group convened in 1981 (the *Ad Hoc* Technical Working Group on Development of Management Principles and Guidelines for Subsistence Catches of Whales by Indigenous [Aboriginal] Peoples) agreed to the following working definition of aboriginal subsistence whaling and related concepts (IWC 1982):

- *Aboriginal subsistence whaling* means whaling for purposes of local aboriginal consumption carried out by or on behalf of aboriginal, indigenous, or native peoples who share strong community, familial, social, and cultural ties related to a continuing traditional dependence on whaling and the use of whales.
- *Local aboriginal consumption* means traditional uses of whale products by local aboriginal, indigenous, or native communities in meeting their nutritional, subsistence, and cultural requirements. The term includes trade in items which are by-products of subsistence catches.
- *Subsistence catches* are catches of whales by aboriginal subsistence whaling operations.

The IWC has not formally adopted the 1981 *Ad Hoc* Technical Working Group's definition of aboriginal subsistence whaling. The same 1981 *Ad Hoc* Technical Working Group also developed three broad objectives for the IWC to use when evaluating aboriginal subsistence whaling

proposals from contracting governments. The IWC did formally adopt these three principles in Resolution 1999-4:

- To ensure that the risks of extinction to individual stocks are not seriously increased by subsistence whaling.
- To enable aboriginal people to harvest whales in perpetuity at levels appropriate to their cultural and nutritional requirements, subject to the other objectives.
- To maintain the status of whale stocks at or above the level giving the highest net recruitment and to ensure that stocks below that level are moved towards it, so far as the environment permits.

In 2018, the IWC Scientific Committee finalized an Aboriginal Whaling Management Procedure (AWMP), which applies stock-specific strike limit algorithms (SLAs) to provide advice on ASW strike and catch limits (IWC 2018a). The AWMP relies on four main components, several of which have scientific subcomponents: (1) SLAs used to provide advice on the strike and catch limits; (2) operational rules, including carryover provisions, block quotas, and interim relief allocations; (3) guidelines for implementation reviews; and (4) guidelines for data and analysis (IWC 2018a). At its 2018 meeting, the Scientific Committee reviewed the hunt management plan proposed by the United States for the Makah Tribe and found that it met the Commission's conservation objectives for WNP and ENP (including PCFG) gray whales. The Committee also reviewed the proposed strike and landing limits as well as the strike carryover provision using the SLA developed for ENP gray whales and found that the proposed Amendment to the Schedule for gray whales met the Commission's conservation objectives (IWC 2018a). In 2023, the Scientific Committee reviewed new information on ENP gray whale abundance and stock structure and concluded that the SLA and Makah Management Plan are robust to the current UME as well as future mortality events (Punt et al. 2023, IWC 2023a).

The IWC does not have a formal definition of aboriginal use of whale products for 'local consumption and distribution.' We interpret the IWC's 2004 subsistence use definition and the current Schedule regarding local distribution as proposed by the Makah to mean that the Makah could share whale products from any hunt within the borders of the United States with the following:

- Relatives of participants in the harvest;
- Others in the local community (both non-relatives and relatives);
- Persons in locations other than the local community with whom local residents share familial, social, cultural, or economic ties.

1.2.4.1.4 United States' IWC Interagency Consultation

The United States, as a contracting government to the ICRW, recognizes the IWC as the global organization with the authority to manage whaling. The United States' negotiating positions at the IWC are advanced by the United States Commissioner to the IWC; the United States Commissioner is appointed by the President and serves at his or her pleasure. The United States Commissioner is not a federal agency. Negotiating positions advocated by the United States Commissioner on behalf of the United States are not final agency actions; these positions may change during the negotiations. The United States' negotiating positions advocated before the IWC, moreover, may or may not be adopted by the IWC, and any attempt to analyze effects on the human environment would be speculative. The United States Commissioner is not required to conduct an analysis under NEPA of United States negotiating positions, and this EIS does not undertake such an analysis.

The United States nevertheless conducts both a NMFS internal review and a public review of whaling issues before making any requests to revise catch limits in the Schedule. When the United States receives a request from a Native American tribe to whale for subsistence purposes, NMFS' Office of International Affairs, Trade, and Commerce, the United States Commissioner to the IWC, and the Department of State first review the request. The United States Commissioner may also consult with other federal agencies as appropriate. Before each IWC meeting, the United States Commissioner presents the draft United States position on whaling issues, including proposals to revise aboriginal subsistence whaling catch limits, to the public at the IWC Interagency Committee meeting. These interagency meetings take place before each full meeting of the IWC, in the Washington D.C. area, and they are open to the public with an interest in whaling, except for individuals representing foreign interests. Representatives of environmental and animal rights groups, Native American groups, sustainable use groups, and other concerned stakeholders typically attend. When relevant, Makah whaling issues have been discussed at public IWC Interagency meetings since May of 1995. The 2022 meeting occurred in Silver Spring, Maryland on September 27, 2022 (87 FR 57181, September 19, 2022). In each case, attendees have reviewed and commented on the draft United States position at the IWC related to requesting revisions of catch limits in the Schedule.

1.2.4.2 National Whaling Governance under the WCA

1.2.4.2.1 United States' Acceptance or Rejection of IWC Regulations

Congress enacted the WCA to implement the domestic obligations of the United States under the ICRW. Under Section 916b of the WCA, the Secretary of State (with concurrence by the

Secretary of Commerce) has the vested power to present or withdraw objections to regulations of the IWC on behalf of the United States as a contracting government.

1.2.4.2.2 National Prohibition of Commercial Whaling

Section 916c(a) of the WCA makes it "unlawful for any person subject to the jurisdiction of the United States . . . to engage in whaling in violation of the [ICRW] or of any regulation of the [IWC]." NMFS' regulations prohibit whaling, except for aboriginal subsistence whaling (50 CFR 230.2).

1.2.4.2.3 United States Aboriginal Subsistence Whaling

The Secretary of Commerce holds general powers, currently delegated to NMFS, to administer and enforce whaling laws and regulations in the United States, including adoption of necessary regulations to carry out that authority. As noted above, the regulations prohibit whaling, except for aboriginal subsistence whaling, which is defined as "whaling authorized by paragraph 13 of the [IWC] Schedule" (50 CFR 230.2). We publish in the Federal Register the aboriginal subsistence whaling quotas set in accordance with paragraph 13 of the Schedule, together with any relevant restrictions, and incorporate them into cooperative management agreements with tribes (50 CFR 230.6(a)).

We may not necessarily publish a quota, even where an IWC catch limit is set for a particular stock. For instance, we have not published a quota for ENP gray whales for the Makah since 2001, even though the IWC has set a catch limit. To authorize the proposed Makah whale hunting, we would have to publish an aboriginal subsistence whaling quota in the Federal Register annually for the Makah's use. We would also have to enter into a cooperative management agreement with the Makah Tribe.

Publication of a quota, as well as consideration of any cooperative management agreement with the Tribe, is contingent upon completion of this NEPA review and the MMPA formal rulemaking procedures described above. Any published quotas are allocated to each whaling village or tribal whaling captain by the appropriate Native American whaling organization (entities recognized by NMFS as representing and governing the relevant Native American whalers for the purposes of cooperative management of aboriginal subsistence whaling).

WCA regulations track the IWC provisions that prohibit whaling of any calf or whale accompanied by a calf (50 CFR 230.4(c)). They also prohibit any person from selling or offering for sale whale products from whales taken in aboriginal subsistence hunts, except that authentic articles of native handicrafts may be sold or offered for sale (50 CFR 230.4(f)). Regulations also

require that whaling not be conducted in a wasteful manner (50 CFR 230.4(k)), meaning a method of whaling that is not likely to result in the landing of a struck whale or that does not include all reasonable efforts to retrieve the whale (50 CFR 230.2).

The WCA and its implementing regulations require licensing and reporting. No one may engage in aboriginal subsistence whaling except a whaling captain or a crewmember under the whaling captain's control. Whaling captains are identified by the relevant Native American whaling organization that must provide evidence or an affidavit that the whale catcher (i.e., vessel) is adequately supplied and equipped and has an adequate crew (WCA Section 916d(d)(1) and 50 CFR 230.4(d)). The license may be suspended if the whale captain fails to comply with WCA regulations (50 CFR 230.5(b)).

If any tribe salvages a stinker (a dead, unclaimed whale found upon a beach, stranded in shallow water, or floating at sea, 50 CFR 230.2), it must provide NMFS with an oral or written report describing the circumstances of the salvage within 12 hours of the event (50 CFR 230.7). No person may receive money for participation in aboriginal subsistence whaling (WCA Section 916d(d) as implemented through 50 CFR 230.4(e)). The whaling captain and Native American whaling organization are also responsible for reporting the number, dates, and locations of strikes, attempted strikes, or landings of whales, including certain data from landed whales, to NMFS (50 CFR 230.8).

1.2.4.3 Application of the WCA to Makah Whaling

The United States seeks IWC approval of an appropriate catch limit before authorizing any aboriginal subsistence whaling under the WCA (NMFS 2001a).

The Makah Tribe believes that the United States' obligation to the Makah Tribe takes precedence over United States obligations under the ICRW (Makah Tribe 2005a). Although the Makah Tribe does not believe that the Makah subsistence harvest requires IWC approval, the Tribe has worked cooperatively with the United States government to obtain that approval. At the IWC's annual meeting held in July 2018, the IWC approved an aboriginal subsistence whaling landing limit of 980 gray whales for 2019 through 2025, limited to a maximum of 140 strikes per year (IWC 2018b). The catch limit was based on the joint request of the United States and the Russian Federation. A bilateral agreement between the United States and the Russian Federation (i.e. Fominykh and Wulff 2023) allocates the catch limit between the Makah Tribe and Chukokta Natives, as described above. The United States currently holds the aboriginal subsistence whaling quota for the ENP gray whale stock on behalf of the Makah, but we have not published it in the Federal Register because of the pending regulatory processes described in this EIS.

1.2.5 Other Applicable Laws

Other laws that may apply to issuance of a waiver include the federal Coastal Zone Management Act (16 USC §1451 et seq.) (CZMA) and Endangered Species Act (16 USC §1531 et seq.) (ESA). The CZMA requires that any federal agency activity "within or outside the coastal zone that affects any land or water use or natural resource of the coastal zone shall be carried out in a manner which is consistent to the maximum extent practicable with the enforceable policies of approved State management programs," (16 USC §1456). NMFS submitted a consistency determination for the ALJ's recommended decision to the Washington State Department of Ecology pursuant to Section 307 of the CZMA on April 18, 2023. The Department of Ecology reviewed our determination and concurred that the proposal is consistent with Washington Coastal Zone Management Plan on June 2, 2023. Potential effects of the alternatives on coastal zone uses and natural resources are discussed in Chapter 4.

The ESA requires that all federal agencies ensure that their proposed actions are not likely to jeopardize any ESA-listed species or destroy or adversely modify designated critical habitat. Section 3.5, Other Wildlife, identifies the ESA-listed species present in the action area, while Section 4.5 discusses effects to ESA-listed species under each alternative. NMFS's Office of Protected Resources (OPR) consulted with the United States Fish and Wildlife Service (USFWS) under Section 7 of the ESA on the impacts of the ALJ's recommended decision to bull trout (*Salvelinus confluentus)* and marbled murrelets (*Brachyramphus marmoratus*). In a Letter of Concurrence (LOC) dated March 25, 2023, the USFWS concluded that all of the reasonably foreseeable exposures and effects of the recommended decision to bull trout and marbled murrelets, as well as their habitats, are insignificant and/or discountable (USFWS 2023a). NMFS OPR also consulted with the NMFS WCR under Section 7 of the ESA on the impacts of the recommended decision to listed fish, sea turtles, and marine mammals, including WNP gray whales. In an LOC dated November 8, 2023, NMFS WCR concluded that the proposed action is not likely to adversely affect the listed species under NMFS jurisdiction in the action area. NMFS WCR also concluded that the proposed action is not likely to adversely affect designated critical habitat for the Mexico DPS and Central America DPS humpback whales, Southern Resident killer whales, Pacific DPS leatherback sea turtles, and southern DPS green sturgeon. Finally, NMFS WCR concluded that the action would not adversely affect any essential fish habitat (EFH) in the action area, therefore consultation under the Magnuson-Stevens Fishery Conservation and Management Act (MSA) is not required (NMFS 2023a). These LOCs from the USFWS and NMFS WCR can be found at https://www.fisheries.noaa.gov/west-coast/marine-mammal-protection/makah-tribal-whale-hunt.

1.3 Purpose and Need for Action

1.3.1 Purpose for Action

NMFS' purpose is to implement the laws and treaties that apply to the Tribe's request, including the Treaty of Neah Bay, the MMPA, and the WCA. The Makah Tribe's purpose is to resume its traditional hunting of gray whales under its treaty right, as described in detail in Subsection 2.3.2, Alternative 2 (Tribe's Proposed Action).

1.3.2 Need for Action

. NMFS' need for this action is to implement its federal trust responsibilities to the Makah Tribe with respect to the Tribe's reserved whaling rights under the Treaty of Neah Bay. In meeting this need, NMFS must also comply with the requirements of the MMPA and the WCA. Under the MMPA, we must protect and conserve the gray whale population; under the WCA, we must regulate whaling in accordance with the ICRW and IWC regulations. The Makah Tribe's need for the action is to exercise its treaty whaling rights to provide a traditional subsistence resource to the community and to sustain and revitalize the ceremonial, cultural, and social aspects of its whaling traditions.

1.3.3 Decisions to Be Made

We are conducting this environmental review under NEPA as a step in the evaluation of the Makah's proposal to hunt gray whales. This FEIS evaluates the effects of the Tribe's proposed action and six alternative actions (including the No-action Alternative and the Preferred Alternative) on the human environment (both social and biological), as well as suitable mitigation measures. By examining the direct, indirect, and cumulative impacts of the proposed action and a full range of alternatives, relative to the No-action Alternative, the FEIS will provide information necessary for the NMFS decision maker to make an informed decision on the Tribe's proposed action.

1.4 Background and Context

1.4.1 Summary of Aboriginal Subsistence Whaling Catch Limits

1.4.1.1 Worldwide Catch Limits

Before 1976, the IWC provided an exemption for aboriginal subsistence whaling. Since 1976 (and 1979 for gray whales), the relevant provisions of the IWC Schedule addressing aboriginal subsistence whaling are in paragraph 13. Paragraph 13(a)(5), in particular, provides that "all aboriginal whaling shall be conducted under national legislation that accords with this

paragraph." The IWC has regulated aboriginal subsistence whaling through catch limits set under paragraph 13(b) of the Schedule. These limits include the following stocks:

- Bering-Chukchi-Beaufort Seas (BCB) stock of bowhead whales (the stock of interest to Alaska Natives and Chukotka Natives under management control of the United States and the Russian Federation, respectively);
- ENP gray whale stock (the stock of interest to the Makah Tribe and Chukotka Natives under management control of the United States and the Russian Federation, respectively);
- West Greenland and Central Stocks of minke whales, West Greenland stock of fin whales, a West Greenland bowhead feeding aggregation, and a West Greenland humpback feeding aggregation (stocks of interest to the Greenlanders under control of Denmark);
- North Atlantic humpback whales (stocks of interest to the Bequians, under control of St. Vincent and the Grenadines).

Canada's First Nation members have also harvested bowhead whales, but they are not currently operating under IWC catch limits set in the Schedule, because Canada is not a party to the ICRW. Maa-Nulth First Nations on Vancouver Island made an agreement with the Canadian government in December 2006 to forgo their traditional right to hunt gray whales for at least 25 years, in exchange for land, a share of mineral and timber resources on that land, and a cash settlement (CBC News 2006; Indian and Northern Affairs 2006).

Subsection 3.17.3.2.3, Aboriginal Subsistence Whaling, provides more detail about aboriginal subsistence whaling, including the contracting governments' reported number of whales harvested.

1.4.1.2 United States Catch Limits

The United States has requested that the IWC revise catch limits in the Schedule on behalf of two native groups: the Alaska Natives and the Makah Tribe. These are the only two native groups in the United States that have asked the government to request revisions to catch limits in the Schedule from the IWC on their behalf. Alaska Natives are exempt from the MMPA take moratorium under Section 101(b).

1.4.1.2.1 Relevant Overview of Requests for Bowhead Whales on Behalf of Alaska Natives

Relevant information about the United States' requests for bowhead whale catch limits on behalf of the Alaska Natives is presented here because the history gives context to the current IWC process described above in Subsection 1.2.4.1.3, IWC Aboriginal Subsistence Whaling.

Like Makah hunting of gray whales, Alaska Natives have hunted bowhead whales as an important species for subsistence and for social and cultural purposes for at least 2,000 years (Stoker and Krupnik 1993). Hunting bowhead whales in Alaska remains a communal activity that supplies meat and maktak (whale skin and layer of blubber that is used for food) for the entire community, as well as for feasts and during annual celebrations. Formalized patterns of hunting, sharing, and consumption characterize the modern bowhead hunt. The bowhead hunt is the principal activity through which younger generations learn traditional skills for survival in the Arctic. It also provides ongoing reinforcement of the traditional social structure. In addition to being a major source of food, the bowhead subsistence hunt is a large part of the cultural tradition of these communities and helps define their modern cultural identity (Braund and Associates 1997).

Since 1976, the United States, on behalf of the Alaska Eskimos, has requested that the IWC revise the bowhead catch limits in the Schedule, and the IWC has set catch limits for the bowhead whale stock in the Schedule. The United States and the Russian Federation share a quota based on the IWC one-time 7-year catch limits (2019 through 2025) for the Western Arctic bowhead stock, approved at the annual meeting of the IWC in September of 2018. The catch limit is allocated between the United States and the Russian Federation through a bilateral agreement (i.e. Fominykh and Wulff 2023).

1.4.1.2.2 Overview of Requests for ENP Gray Whales on Behalf of the Makah

Prior to 1989, the IWC had set an annual aboriginal subsistence catch limit based on a request on behalf of Chukotka Natives. On May 5, 1995, approximately one year after the ENP gray whale was removed from the endangered species list, the Makah Tribal Council formally notified NMFS of its interest in re-establishing ceremonial and subsistence hunts for gray whales (Makah Tribal Council 1995). The Tribe anticipated harvesting only one or two whales initially, but included five as the maximum extent of the yearly harvest, if it determined that it could use additional whales effectively and allocate them to each of five ancestral villages (Makah Tribal Council 1995). The Makah agreed not to sell whale meat commercially, developed a comprehensive needs statement, and entered into a cooperative management agreement with NMFS to manage the whale hunt. At the 1995 annual meeting of the IWC, the United States did not request that the IWC revise the Schedule to set a catch limit for the ENP gray whale stock, but informed the IWC that it intended to submit a formal proposal on the Makah's behalf in the future (IWC 1996).

At the annual meeting of the IWC in 1996, the United States, on the Makah's behalf, requested that the IWC revise the Schedule to set a catch limit for the ENP gray whale stock of 20 ENP gray whales over 5 years (with no more than five in any one year) from 1997 through 2000. At the Aboriginal Subsistence Whaling Subcommittee meeting, many delegates supported the United States' request. Other delegates indicated they would vote against the proposal. One reason given for this opposition was that the United States did not ask the Russian Federation to share the existing 1995 to 1997 catch limit of 140 ENP gray whales per year, which was based on the cultural and nutritional needs of the Chukotka Natives (IWC 1997; 63 FR 16701, April 6, 1998). Instead, the United States adhered to a prior position that each contracting government requesting a revision to the Schedule for aboriginal subsistence whaling catch limits must submit its own proposal before the IWC (IWC 1997; 63 FR 16701, April 6, 1998). Opponents noted that granting the United States' request would increase the total ENP gray whale catch limit beyond what had already been set by the IWC in paragraph 13(b)(2) of the Schedule (IWC 1997). At the 1996 meeting, the Russian Federation had also requested a catch limit of five bowhead whales a year, but withdrew its request when a consensus could not be reached among delegates. The bowhead stock catch limit was already set for the United States and was not shared with Russia (IWC 1997).

Another reason for the opposition was that some delegates questioned whether the Makah had a "continuing traditional dependence" on whaling (IWC 1997), a component of the working definition for aboriginal subsistence whaling developed by the 1981 *Ad Hoc* Technical Working Group (Subsection 1.4.1.2.1, Relevant Overview of Requests for Bowhead Whales on Behalf of Alaska Natives). The delegates noted that the Makah had not hunted gray whales since the 1920s (IWC 1997).

United States delegates and Makah representatives responded that the Makah Tribe had continued aspects of its whaling tradition through names, dance, songs, and other cultural traditions (IWC 1997; United States 1996). The United States also noted that nutritional need is a factor in considering and setting aboriginal subsistence whaling catch limits, but not a threshold requirement. United States delegates used the example of the IWC setting a catch limit for the bowhead stock for many years after considering the United States' requests on behalf of the Alaska Natives, even though the Nutrition Panel at the 1979 workshop for aboriginal subsistence whaling of bowhead concluded that nutritional needs of Alaska Natives could be met through local subsistence or western-type foods (IWC 1979b; United States 1996). Moreover, the Makah needs statement (Renker 1996) had demonstrated a continued subsistence reliance on traditional

marine foods available to the Makah, and a nutritional need based on poverty and economic conditions on the Makah Reservation (Renker 1996; United States 1996). The United States noted that federal agents in the last 5 decades had actively prevented Makahs from consuming and utilizing whales that drifted onto Makah beaches, by burying or burning the drift whales and by threatening Makah members, who tried to access the products, with jail and other federal sanctions (United States 1996). As late as the 1970s, federal agents were still entering Makah households and searching freezers for the presence of marine mammal products (United States 1996).

Attendees of the 1996 meeting were also aware of other conflict regarding the Makah's proposal to hunt; the United States House of Representatives Committee on Resources had unanimously passed a resolution expressing opposition to the Makah hunt (United States Congress 1996), and some members of the Makah Tribe testified against the United States proposal at the IWC meeting. The United States made a statement in appreciation of the support from some delegates, noted the reservations expressed by others, and after consultation with the Makah Tribe announced that it was withdrawing its request for an amendment to the Schedule for the gray whale catch limit. The United States asked the IWC to defer consideration until the next year, when the ENP gray whale catch limit was due to expire and the needs of the Chukotkan people were also determined (IWC 1997).

In preparation for the annual meeting of the IWC in 1997, the United States considered comments made at the 1996 meeting that the gray whale catch limit should be shared with the Russian Federation, making the combined requests 140 rather than 145 gray whales per year (63 FR 16701, April 6, 1998). The gray whale catch limit set in the Schedule for the Russian Federation (acting on behalf of the Chukotka Natives) was due to expire in 1997, so the Russian Federation would have to propose a Schedule amendment for a new catch limit from 1998 through 2002 (63 FR 16701, April 6, 1998). After extensive discussions with the Alaska Eskimo Whaling Commission and the Makah Tribe, as well as an internal policy review, the United States delegation consulted with the Russian Federation delegation on the appropriate formulation for a request (63 FR 16701, April 6, 1998). The Makah made efforts to augment their needs statement and request, including conducting research and training on the proposed method of hunting whales (such as conducting field tests of rifles with Dr. Ingling, a veterinarian with IWC experience). They also gathered more information about the nutritional value of subsistence foods in their diet.

At the Aboriginal Subsistence Whaling Subcommittee meeting on October 18, 1997, the United States raised several points in support of the proposal: (1) law (the Treaty of Neah Bay specifically reserves the right of the Makah to hunt whales), (2) culture (the Makah have a 1,500-year tradition of whaling that has been of central importance to their culture), (3) science and conservation (there would be no adverse conservation impacts to the stock), and (4) Makah progress on improving the needs statement and request since the last IWC meeting (United States 1996; IWC 1998). Related to this last point, Dr. Ingling presented results of field trials on the weapon, ammunition, and techniques to be used in the Makah hunt (Ingling 1997; IWC 1998). A representative of the Makah Tribal Council also spoke, emphasizing the central focus and importance of whaling to Makah culture (IWC 1998). Opponents again raised concerns about the interruption in the Makah whaling practice. Some delegates thought the Makah did not demonstrate nutritional and/or cultural need, based on the 1981 *Ad Hoc* Technical Working Group definitions of aboriginal subsistence whaling and consumption, while others stated that discontinuity of whaling practice should not be held against the Makah, because they were deprived of cultural and traditional rights (IWC 1998). Some delegates thought the Makah had established cultural need beyond a doubt (IWC 1998).

At the 1997 IWC plenary session, the United States and the Russian Federation presented joint requests for bowhead and ENP gray whale catch limits to accommodate the needs of two aboriginal groups hunting from a single stock (Alaska Natives and Chukotka Natives hunting bowheads and the Makah Tribe and Chukotka Natives hunting ENP gray whales). This was the first year in which two contracting governments simultaneously requested revisions to the Schedule for catch limits from the same stock. For the bowhead stock, delegates considered the joint request and adopted the catch limit of 280 bowhead whales for the 1998 through 2002 5-year period, with a maximum limit of 67 per year, by consensus on the afternoon of October 22, 1997 (IWC 1998). The bowhead catch limit was allocated between the Russian Federation and the United States by a bilateral agreement.

For the ENP gray whale stock, the joint request of 620 gray whales for the 1998 through 2002 5-year period, with a maximum limit of 140 gray whales per year, was debated in IWC plenary session on the afternoon of October 22, 1997 (63 FR 16701, April 6, 1998). Several delegates opposed the Makah Tribe's request, while others supported it (IWC 1997). Some delegates suggested making an amendment to the introductory portion of the proposal. The debate session then adjourned to allow for consultation among the delegates (63 FR 16701, April 6, 1998).

Specifically, two delegates proposed that the following words be added to paragraph 13(b)(2) of the Schedule: "whose traditional subsistence and cultural needs have been recognized by the International Whaling Commission" (IWC 1998). United States delegates responded that the words "by the International Whaling Commission" were not acceptable, because the IWC had no established mechanism for recognizing such needs, other than adoption of a catch limit in the Schedule (63 FR 16701, April 6, 1998). The United States delegates expressed their understanding that adoption of a catch limit in the Schedule constituted IWC approval, with no further action required. A clear majority of Commissioners then expressed their support for the United States' approach (63 FR 16701, April 6, 1998).

When the plenary session resumed, the Chair announced consensus. The joint request of the United States and the Russian Federation for an ENP gray whale catch limit was adopted on October 23, 1997, with the addition of the words "whose traditional aboriginal subsistence and cultural needs have been recognized" to the Schedule language (63 FR 16701, April 6, 1998; IWC 1998). The ENP gray whale catch limit was allocated between the Russian Federation and the United States by a bilateral agreement (120 gray whales per year for the Chukotka Natives, and an average of four gray whales per year, with a maximum of five, for the Makah).

At the annual meeting of the IWC in 2002, the IWC adopted by consensus a catch limit of 620 ENP gray whales for the 2003 through 2007 5-year period. The catch was limited to 140 takes per year, based on a second joint request of the United States and the Russian Federation (IWC Schedule 2002), which was similar to the first successful joint request in 1997. The United States and Russian Federation then allocated the ENP gray whale catch limit by bilateral agreement, to a maximum of 20 whales over the 5-year period and up to five whales annually for the Makah, and a maximum of 600 gray whales over the five-year period and up to 135 per year for the Chukotka Natives.

At the annual meeting of the IWC in 2003, the Russian Federation noted anomalies in the Schedule about the way that Chukotka Natives are treated compared with other aboriginal groups operating under aboriginal subsistence whaling auspices (IWC 2004a; IWC 2004b). They proposed changes to the Schedule, including changes to paragraph 13(b)(2). Paragraph 13(b)(2) read as follows:

> [t]he taking of gray whales from the Eastern stock in the North Pacific is permitted, but only by aborigines or a Contracting Government on behalf of aborigines, and then only when the meat and products of such whales are to be used exclusively for local consumption by the aborigines whose traditional aboriginal subsistence and cultural needs have been recognized. . . .

The Russian Federation proposed to delete the words "whose traditional aboriginal subsistence and cultural needs have been recognized" (IWC 2004a; IWC 2004b). The Russian Federation's stated objective was to achieve consistency in the Schedule and to, therefore, eliminate discriminatory behavior against the native peoples of Chukotka, because they interpret such language restrictions as preventing the important practice of cultural exchange of goods among indigenous peoples (IWC 2004a; IWC 2004b). The IWC subsequently charged a small group, comprising the Russian Federation, Denmark, Australia, the United States, and the IWC Secretariat, to review paragraph 13 of the Schedule to determine how to achieve consistency across aboriginal subsistence whaling operations (IWC 2004a).

The small group submitted a report to the Aboriginal Subsistence Whaling Subcommittee at the annual meeting of the IWC in 2004 (IWC 2005a; IWC 2005b), together with proposed changes to the Schedule. The report had two key recommendations: (1) move the prohibition on take of calves and mother/calf pairs to the general principles governing all hunts in paragraph 13(a), and (2) delete the language, "the aborigines whose traditional aboriginal subsistence and cultural needs have been recognized" from paragraph 13(b)(2) of the Schedule (IWC 2005a; IWC 2005b). The latter recommendation was related to the Russian Federation's interpretation that the quoted provision violated the human rights of Chukotka Natives, because the restriction was not included in other subparagraphs governing aboriginal subsistence whale hunts and, therefore, improperly discriminated against the Chukotka Natives (IWC 2005a; IWC 2005b). The Russian Federation maintained that the Chukotka Natives have equal rights to other aboriginal communities to use whale products (IWC 2005a; IWC 2005b).

At the 2004 IWC plenary session, delegates adopted the report of the small group and the proposed Schedule amendments by consensus, with one revision (they retained a calf and mother/calf take prohibition specific to St. Vincent and the Grenadines). Since 2004, the Schedule has read as follows for the ENP gray whale stock catch limit:

> [T]he taking of gray whales from the Eastern stock in the North Pacific is permitted, but only by aborigines or a Contracting Government on behalf of aborigines, and then only when the meat and products of such whales are to be used exclusively for local consumption by the aborigines (IWC Schedule 2005 and subsequent years, paragraph 13(b)(2)).

The IWC also adopted the 1979 Cultural Anthropology Panel's definition of subsistence use in 2004. See Subsection 1.2.4.1.3, IWC Aboriginal Subsistence Whaling, for more details about the text of the current Schedule, as well as for the text of the formally adopted definition on subsistence use.

On February 14, 2005, the Makah initiated their current proposal to hunt ENP gray whales and submitted a request for a waiver of the MMPA take moratorium to NMFS. NMFS had not published the 2003 through 2007 quota under the WCA because of the 2004 decision in *Anderson v. Evans*. In October 2005, the House of Representatives Committee on Resources passed a non-binding resolution (House of Representatives Congressional Resolution 267) by a vote of 21 to 6, expressing disapproval of the MMPA waiver process and stating that the United States should uphold the treaty rights of the Makah Tribe. The Committee's report (House Report 109-283) was placed on the House of Representatives' calendar without further action.

At the May 2007 IWC meeting, the United States and the Russian Federation again made a joint request for an ENP gray whale catch limit from the IWC for the 2008 through 2012 5-year period under similar terms as the last catch limit for 2003 through 2007. The catch limit was approved by consensus. At the July 2012 meeting, the IWC agreed to biennial meetings and set a 6-year catch limit to match the Commission meeting schedule. Commissioners at the 2012 meeting approved quotas for the hunts of Bering-Chukchi-Beaufort Seas bowhead whales (by the United States and Russian Federation), eastern North Pacific gray whales (by the Russian Federation and the United States), and western North Atlantic humpback whales (St. Vincent and the Grenadines). Given the proposed move to biennial meetings, the quota block was extended to 6 years by a vote of 48 to 10 (IWC 2012b). The ENP gray whale catch limit was set at 744 over the 6-year period, not to exceed 140 in any single year (IWC 2012c).

At the September 2018 IWC meeting, the United States, the Russian Federation, Denmark, and St. Vincent & the Grenadines made a joint request to renew all ASW catch limits for a one-time 7-year period lasting from 2019 through 2025. The U.S. and the Russian Federation once again submitted their requests for ENP gray whales and BCB bowhead whales jointly, increasing the catch limit to account for the additional 7th year in the quota block. The ENP gray whale quota request also increased the annual strike limit from the previous Schedule to account for "stinky" whales – a recent phenomenon in which some landed gray whales are found to have a strong chemical smell and are inedible – and to satisfy ASW subsistence need (IWC 2018c). The catch limit was approved by the three fourths majority vote required to amend the Schedule. At the 69th Commission meeting in 2024, catch limits will be renewed for a 6-year period in accordance with advice from the Scientific Committee.

1.4.2 Summary of Recent Makah Whaling ─ 1998 through 2022

In 1998, NMFS published in the Federal Register a yearly quota of up to five gray whales for the Makah (63 FR 16701, April 6, 1998), operating under the IWC's 1998 to 2002 5-year catch limit.

Although the Makah Tribal Council issued several whaling permits and tribal whalers conducted a number of practice exercises, they did not actually hunt whales that year. Protest activities and conflicts near and on the shores of Neah Bay during 1998 are described in Public Safety, Subsection 3.15.3.4, Behavior of People Associated with the Hunt. Protest vessels mobilized on November 11, 1998, but in response to a false report that the Tribe was hunting and had harvested a whale (United States Coast Guard 1998).

During the spring northward migration in 1999, NMFS again published in the Federal Register a yearly quota of up to five gray whales for the Makah (64 FR 28413, May 26, 1999). The Makah Tribal Council issued a 10-day whaling permit to a Makah whaling captain on May 10, 1999, based on the recommendation of the Makah Whaling Commission acting in accordance with the 1998 Gray Whale Management Plan. Whale hunting spanned 4 nonconsecutive days (May 10, 11, 15, and 17) and all hunts were conducted in the coastal portion of the Makah's U&A, south of Cape Flattery (i.e., outside the Strait of Juan de Fuca) to target whales migrating northward. Two vessels and crews were directly involved in the whale hunting activities, including the Makah whaling crew in their canoe, *The Hummingbird*, and a rifleman, backup harpooner, and diver on board the tribal chase boat. NMFS and Makah tribal fisheries observers were on board the NOAA observer boat *Research II*. In addition, media helicopters, one or two chartered media vessels, protest vessels, Coast Guard law enforcement, and shore-based supporters and opponents were present most of the time. A tribal commercial fishing boat, acting as a support vessel, was also nearby and available to assist the whalers.

On May 10, 1999, the first day of whale hunting, the Makah crew searched for gray whales within 3 miles (5 km) of shore near Father and Son Rock, Cape Alava, Spike Rock, Umatilla Reef, and Point of the Arches (Gosho 1999; United States Coast Guard 1999a). At least four whales were sighted throughout the day, with three of the four sightings occurring in 115 to 134 feet (35 to 41 meters) of water (Gosho 1999). The observers did not see calf-sized whales in the area (NMFS 1999). The Makah whaling crew threw one harpoon at a whale, but missed it (Gosho 1999; NMFS 1999; NMFS and Makah Tribal Council 2000). The hunt was disrupted by vessel-based protesters who maneuvered between the two Makah vessels and the whales. Protesters tried to scare off the whales, and they also fired flares and smoke flares at the Makah whaling party vessels (NMFS 1999; Sunde et al. 1999; United States Coast Guard 1999a).

Because most of the hunting occurred south of the Coast Guard's regulated navigation area (RNA), a 500-yard (457.2-meter) moving exclusionary zone (MEZ) around the Makah vessels was not in effect (NMFS 1999). Coast Guard officials detained two of the protesters, who they

subsequently cited for grossly negligent operation of a vessel, and the Clallam County sheriff then arrested the protesters for reckless endangerment (NMFS 1999; Sunde et al. 1999; United States Coast Guard 1999a). At least three media helicopters were present (United States Coast Guard 1999a). Hunting on May 11 (day two) continued in the same area, but the Makah whaling captain called it off in a few hours because of poor weather conditions (Gosho 1999; NMFS 1999). No whales were sighted or approached.

Whale hunting resumed on May 15, 1999, day three, near Father and Son Rock, Ozette Island, and the Bodeltehs (Gosho 1999), south of the RNA (NMFS 1999) and within 2 miles (3 km) of shore. Several gray whales were sighted in 87- to 95-foot-deep (26.5- to 29-meter-deep) water, but the Makah crew was unable to maneuver *The Hummingbird* close enough to throw harpoons and was again interrupted by protest vessels (Gosho 1999). Around 11:00 a.m., the whalers sighted a whale and threw a harpoon, which was assumed to contact the whale because the wooden harpoon holder was split, and the float disappeared underwater for a short time (Gosho 1999; NMFS 1999). The strike did not appear to penetrate or embed in the animal because the harpoon head was intact and clean, the throw was parallel to the animal (rather than perpendicular), and the float resurfaced (Gosho 1999; NMFS 1999).

Because the harpoon did not embed in the whale and did not appear to cause serious injury, it did not meet the definition of a strike under the 1998 Gray Whale Management Plan (Gosho 1999; NMFS 1999). Under that plan, a strike counted only if the harpoon embedded in the whale and if it might have resulted in death or serious injury. About an hour later, the Makah harpooner threw another harpoon and missed (Gosho 1999).

Protest vessels were active around the whalers much of the day. Two protest vessels came into contact with whales; one vessel ran over the top of a whale and temporarily stunned it, while another vessel hit the flukes of a diving whale beside the Makah canoe (NMFS 1999). The Coast Guard cited four vessels for grossly negligent operations and/or MMPA take infractions, and three of the vessels were taken into federal custody (NMFS 1999).

On May 17, 1999 (the fourth and final day of whale hunting), the Makah crew continued hunting southwest of Father and Son Rock, south of the RNA. No protest vessels attempted to disrupt the hunt, but three media helicopters covered events throughout the day (United States Coast Guard 1999b). At 6:55 a.m., the Makah crew sighted a whale and pursued it in the canoe; the whale surfaced on the right side of the canoe, and the crew harpooned it as it moved across the bow of the canoe, approximately 1.5 miles (2.4 km) from shore (Gosho 1999; NMFS 1999). The harpoon remained affixed to the whale, which pulled the harpoon line and floats underwater and towed the

canoe (Gosho 1999; NMFS 1999). The whaling crew in the canoe held the harpoon line while the chase boat approached the whale for the Makah rifleman to kill the animal with a .577 caliber rifle. The gunner fired the first and second shots at 6:58 a.m.; both shots missed (Gosho 1999). At 7:01 a.m., a third shot was fired, striking the whale behind the blowhole and slightly to the left, momentarily stunning the whale (Gosho 1999). A second harpoon was also thrown at the whale, striking it on the right side towards the rear (Gosho 1999). The fourth and final shot was fired at 7:03 a.m., striking the whale behind the blowhole slightly to the right, and leaving the whale motionless at the surface (Gosho 1999). Immediately after the final shot, a third harpoon was thrown, striking the whale on the right side (Gosho 1999). The total time to death, from the initial harpoon strike to the last shot that dispatched the whale, was 8 minutes.

The body of the whale sunk and was supported by the lines on the three attached harpoons (Gosho 1999). A Makah diver attached a heavier line around the tail stock of the whale for towing (Gosho 1999), and the whale was towed by a Makah support vessel to inside the breakwater at Neah Bay, where tribal members had gathered on the beach to celebrate the hunt. The whale was transferred from the support vessel to four canoes from various Washington Indian tribes, led by the crew of the Makah *Hummingbird* canoe, and towed from the deeper part of the breakwater into the shallow water at the edge of the beach. The whale was butchered following tribal ceremonies. Tribal members removed almost all edible portions of the meat and blubber from the whale by midnight. NMFS biologists collected samples from internal organs after tribal members removed the meat and took it home or to the community freezer (Gosho 1999; NMFS 1999). Tribal members flensed small portions of meat the next day to prepare the skeleton for a museum display (NMFS 1999; NMFS and Makah Tribal Council 2000). Tribal members consumed the meat and blubber during tribal ceremonies (Gosho 1999; NMFS and Makah Tribal Council 2000; NMFS 1999).

According to measurements taken by NMFS and tribal observers, the harvested whale was a non-lactating female that measured 30 feet, 5 inches (9.27 meters) long. Fluke width was 7 feet, 4 inches (2.2 m). The whale could not be weighed, but, based on gray whales taken by the Russian harvest of similar length and body condition, it was estimated to weigh approximately 5 to 7 metric tons. Age could not be determined either, but, based on similar lengths of whales taken in the Russian harvest, it was probably more than 2 years old. An examination of the skull during butchering revealed that the third shot struck the ridge of the skull, shattering it, and proceeded back into the muscle near the left flipper, where whalers found the bullet (the bullet was intact

with no deformation). The fourth shot struck the skull above the occipital condyle and entered the braincase; it likely caused instantaneous loss of consciousness and death (Gosho 1999).

During the fall/winter southward migration in 1999/2000, the Makah Tribal Council did not issue any whaling permits because weather conditions were unsuitable. Hunting began during the spring northward migration for 7 days between April 17, 2000 and May 29, 2000 (Gearin and Gosho 2000). The Makah tribal whalers actively hunted gray whales in the coastal portion of the Makah U&A south of Cape Flattery for 7 days, during which no whales were harvested, struck, or struck and lost (Gearin and Gosho 2000). Except for a few approaches near Makah Bay, most hunting occurred south of Point of Arches near Father and Son Rock. Makah whalers threw harpoons on three occasions, but the harpoons did not attach to a gray whale on any of these attempts. The first two throws appeared to be complete misses (Gearin and Gosho 2000). The third throw may have grazed the whale; however, the harpoon did not implant or detach (Gearin and Gosho 2000). Most of the whales in the area during the hunt were large, single individuals. The whales appeared to be actively migrating, because the average time between surface sightings (i.e., the average dive time) was about 8 minutes, which is 4 or 5 minutes longer than the average dive time for whales feeding or resting locally, and the whales were farther offshore (i.e., 80 to 100 feet (24.4 to 30.5 meters) deep rather than 30 to 60 feet (9.1 to 18.3 meters) deep) (Gearin and Gosho 2000).

All hunts occurred within the Coast Guard's RNA and MEZ, and all harpoon attempts were made within 2.5 miles (4 km) of shore (Gearin and Gosho 2000). During the first 2 days of hunting (April 17 and 20), protesters disrupted the hunts (Gearin and Gosho 2000). On April 20, Coast Guard personnel boarded two protest vessels and issued warnings (United States Coast Guard 2000). One of the vessels entered the 500-yard (457.2-meter) MEZ on three occasions subsequent to the Coast Guard advisory; the Coast Guard again intercepted and warned it (United States Coast Guard 2000). On at least one of these three entrances into the MEZ, the vessel entered the 500-yard (457.2-meter) MEZ at high speed and was intercepted within 50 yards (45.7 meters) of the Makah's canoe (Gearin and Gosho 2000). Two individuals on jet skis also entered the MEZ, making high speed charges at the Makah canoe (United States Coast Guard 2000). The Coast Guard intercepted both jet skiers. One jet skier ran into a Coast Guard vessel and sustained shoulder injuries; Coast Guard personnel retrieved the individual from the water, placed her under arrest, and transported her to Olympic Memorial Hospital (United States Coast Guard 2000). The Coast Guard also intercepted and arrested the second jet skier, and transferred him to the Clallam County sheriff's office (United States Coast Guard 2000). After a temporary delay, hunting

resumed for 5 nonconsecutive days in May (May 6, 7, 10, 12, and 29). One to three protester vessels were present during these times, but they did not enter the MEZ to disrupt whale hunting (Gearin and Gosho 2000). Media helicopters were present during most of the whale hunting and appeared to comply with the Sanctuary's 2,000-foot (609.6-meter) minimum allowable flight altitude.

Makah whalers had intended to continue whaling into June, but the Makah Tribal Council did not issue any permits after the June 9, 2000 ruling by the Court of Appeals for the Ninth Circuit in *Metcalf v. Daley* (2000). The Makah Tribal Council did not issue any whaling permits during the gray whale southward migration in fall/winter 2000.

The whale harvested in 1999 is the only whale that the Makah have harvested (that is, hunted and successfully landed) in contemporary times. Some Makah members have, however, participated in whale hunt research, education, and training with other indigenous groups. In August of 2005, for instance, two Makah members and a tribal whale biologist traveled to the eastern shores of the Russian Federation. The biologist was involved in an IWC scientific exchange to evaluate the type of data that Chukotka Natives collected in their hunts and to evaluate the logistics of studying the stinky whale phenomenon. The Makah members participated in a cultural exchange to observe the Chukotka gray whale hunts and to receive training in whale hunting techniques and whale butchering.

On September 8, 2007, five members of the Makah Indian Tribe hunted and killed a gray whale in the Strait of Juan de Fuca in a hunt that was not authorized by the Tribe or NMFS. This unauthorized hunt did not comply with numerous provisions and restrictions defined in the Tribe's request, and both the Tribe and NMFS made statements condemning the unlawful hunt (Hogarth 2007; Rosenberg 2007).

The five tribal members used two boats and had in their possession a .577 caliber rifle and a Weatherby .460 caliber rifle (*U.S.A. v. Gonzales et al*. 2007). One of the boats and all of the rifles belonged to the Tribe and were obtained by one of the members of the hunting party (*U.S.A. v. Gonzales et al.* 2007). Sometime on the morning of September 8, the hunters approached a gray whale approximately 40 feet (12.2 meters) long near Seal Rock and harpooned it with at least five harpoons (Mapes 2007). They then shot the whale at least 16 times (*U.S.A. v. Gonzales et al.* 2007). According to a report by the Tribe, none of the members of the hunting party had received tribally sanctioned training in use of the weapons to kill gray whales (Scordino 2007a). A tribal biologist who evaluated the whale's condition in the afternoon of September 8 counted four

visible harpoons and 16 bullet holes (Scordino 2007b). The whale died shortly after 7:00 p.m. on September 8 (Scordino 2007b).

On October 5, 2007, the five tribal members were indicted in federal court for unauthorized whaling, unauthorized take of a marine mammal, and conspiracy to engage in unlawful whaling (*U.S.A. v. Gonzales et al.* 2007). On November 16, 2007, the five were charged in tribal court for violating the Tribe's gray whale management plan, violating state and federal laws, and reckless endangerment (Casey 2007; *Makah Tribe v. Andrew Noel* 2007). On March 27, 2008, three of the tribal members entered guilty pleas to unlawful taking of a marine mammal in violation of the MMPA (*U.S.A. v. Gonzales* 2008; *U.S.A. v. Parker* 2008; *U.S.A. v. Secor* 2008). On April 7, 2008, after a Bench Trial on Stipulated Facts, the court found the remaining two tribal members guilty of conspiracy and unlawful taking of a marine mammal in violation of the MMPA (*U.S.A. v. Noel and Johnson* 2008). All five tribal members received judicial sentences based on the MMPA and the court's evaluation of the seriousness of their conduct. On May 14, 2008, the five tribal members entered into 1-year deferred prosecution agreements in tribal court (*Makah Tribe v. Theron Parker* 2008). No violations were reported to the tribal court during the term of the agreements, and the charges were subsequently dismissed 1 year later.

1.4.3 Other Environmental Assessments and Court Decisions Informing this Action

In 1996, we entered into an agreement with the Makah Tribe to ensure a United States request before the IWC to amend the Schedule's catch limit for the ENP gray whale stock and jointly manage the gray whale hunts. Before we could publish any quota for the Makah Tribe, we had to amend the WCA regulations, which only provided for aboriginal subsistence whaling by the Alaska Eskimo Whaling Commission. We conducted a NEPA analysis on our proposed rule to amend the regulations, and on March 26, 1996 issued a finding that the proposed regulations would not have a significant impact on the environment.

In 1996, the United States' request on behalf of the Makah Tribe to the IWC to revise the Schedule's catch limit for ENP gray whales met with resistance, and the United States withdrew the request. In June 1997, in response to concerns raised by some conservation organizations, we initiated a NEPA process to analyze the environmental impacts of a decision to publish an aboriginal subsistence whaling quota under the WCA for the Makah's use of up to five ENP gray whales annually. The draft EA was released for comment in August 1997. A few months later, we entered into a second agreement with the Makah Tribe. It was similar to the first, except that the second agreement included time and area restrictions aimed at reducing the likelihood of taking a

PCFG whale. We and the Makah entered into the agreement on October 13, 1997, and we issued the final EA and a Finding of No Significant Impact (FONSI) 4 days later.

Conservation groups challenged our FONSI in court, and the Ninth Circuit set aside the EA and FONSI in *Metcalf v. Daley* (2000) because we did not produce them until after entering into the agreement with the Tribe. With the court's invalidation of the EA and FONSI, we terminated the second agreement with the Makah Tribe and began a second NEPA process. On July 12, 2001, we issued a second EA and FONSI regarding a similar Makah whaling proposal. Conservation groups challenged that EA and FONSI in court, and the Ninth Circuit ruled in *Anderson v. Evans* (2004) that we should have prepared an EIS rather than an EA.

On March 6, 2003, we initiated an EIS to assess the environmental impacts of publishing the 2003 to 2007 quota for the Makah's use under the WCA (68 FR 10703). Because of pending litigation, we gave notice 2 years later that we were terminating the EIS (70 FR 49911, August 25, 2005). On August 25, 2005, we published a Notice of Intent (NOI) to prepare an EIS (70 FR 49911) and on February 27, 2006 (71 FR 9781), we announced in the Federal Register that we would expand the scope of the EIS to include the WCA. On May 9, 2008, we published a DEIS evaluating the impacts on the human environment of the Tribe's proposed hunt and five alternatives.

Soon after releasing the 2008 DEIS, several substantive scientific issues arose that required an extended period of consideration for our NEPA analysis, including: (1) potential bias in population estimates for ENP gray whales (Laake et al. 2009); (2) genetic evidence of population substructure indicating that PCFG whales may warrant consideration as a separate management unit (Frasier et al. 2011; Lang et al. 2011a); and (3) whale tracking and sampling data indicating that at least some members of the endangered WNP stock of gray whales migrate across the Pacific and into areas (including the Makah U&A) once thought to be used exclusively by ENP gray whales (see Subsection 3.4.3.2.1, WNP Seasonal Distribution, Migration, and Movements). This information was also under review at the IWC. Given these developments and the fact that it had been 7 years since the Tribe had submitted its initial request, on May 21, 2012, we announced we were terminating the 2008 DEIS and intended to prepare a new DEIS (77 FR 29967).

In making that announcement, we were mindful that we had received over 400 comments on the 2008 DEIS from state and federal entities, tribal governments, and both nonprofit organizations and interested individuals from the United States and around the world. The numerous comments we received covered topics ranging from specific biological, ecological, or legal issues to more general cultural, personal, or spiritual values. For example, a substantial number of the public

comments were concerned with potential hunting impacts on PCFG whales, while others raised questions about issues of precedence on the world stage or the cultural significance of the hunt to the Makah Tribe. Many commenters covered multiple topics in a single letter, and topics often were repeated in multiple comments (although in different combinations). In some cases topics were outside the scope of the DEIS.

In developing the 2015 DEIS, we carefully reviewed the comments on the 2008 DEIS and developed responses to those that provided new information or raised substantive issues. To capture that consideration, and aid reviewers of the 2015 DEIS, we prepared a NMFS memorandum (NMFS 2015a) that lists the comments received on the 2008 DEIS (and either summarizes the comment or repeats the comment verbatim) and includes the draft responses to a number of comments that we considered while developing the 2015 DEIS. The memorandum does not contain responses to each individual comment, given the large number of comments simply raising support or lack of support for a hunt, the significant overlap among the comments provided, and the fact that the 2008 DEIS was terminated. We have also reviewed the comments received on our May 21, 2012 *Federal Register* notice (77 FR 29967) and responded to those in a separate scoping report (NMFS 2015b; refer to Appendix F).

The 2015 DEIS was made available for public comment on March 13, 2015 (80 FR 13373, March 13, 2015) with a public comment period ending on June 11, 2015, which was later extended to July 31, 2015 (80 FR 30676, May 29, 2015). NMFS received over 57,000 comments by mail, fax, email, and submissions to www.regulations.gov (Docket ID: NOAA-NMFS-2012-0104). Over 99% of those comments were submitted as form letters. The NMFS West Coast Region prepared two documents providing initial responses to the comments received—one responding to the 17 topics most frequently raised by commenters on the DEIS and one providing responses to all of the unique comments raised (excluding duplicated form-letter comments). These documents were also included in the ALJ hearing record and are available on the ALJ's hearing website at: https://www.uscg.mil/Resources/Administrative-Law-Judges/Decisions/ALJ-Decisions-2016/NOAA-Formal-Rulemaking-Makah-Tribe/.

After reviewing public comments on the 2015 DEIS and additional information relevant to the Tribe's request, NMFS developed a sixth action alternative that was not separately analyzed in the 2015 DEIS but is composed of elements from other alternatives that were analyzed. Based on this 'composite alternative,' NMFS published the proposed decision (84 FR 13604, April 5, 2019) to issue a waiver under the MMPA and proposed regulations governing the hunting of ENP gray whales by the Makah Tribe for a 10-year period.

Also, in May of 2019, NMFS declared an Unusual Mortality Event (UME) for ENP gray whales after a larger than normal number of whales were reported stranded during their migration between Arctic feeding grounds and Mexican breeding grounds (see information posted at https://www.fisheries.noaa.gov/national/marine-life-distress/2019-gray-whale-unusual-mortality-event-along-west-coast). While the 2015 DEIS discussed UMEs in general and a previous ENP gray whale UME, which was declared in 1999-2000, it pre-dated the ongoing 2019 UME.

NMFS determined that it would benefit both the public and agency decision-making to prepare a Supplemental Draft Environmental Impact Statement (SDEIS) to address (1) the composite alternative that comprised the proposed regulations, (2) the ongoing UME, and (3) the ALJ's Recommended Decision and corresponding hearing record and public comments. On February 27, 2020, NMFS announced in the *Federal Register* a notice of intent to prepare an SDEIS to supplement the 2015 DEIS (85 FR 11347). The SDEIS analyzed in aggregate the components of the previously analyzed elements that comprise Alternative 7 and provided the opportunity for public review and comment.

On July 5, 2022, NMFS published a *Federal Register* notice regarding availability of the SDEIS and a request for public comment during a 45-day comment period (87 FR 39804), which was extended twice for a total of 67 additional days (87 FR 50319, August 16, 2022, and 87 FR 64454, October 25, 2022). NMFS received 47 public comments by mail, email, and submissions to www.regulations.gov (Docket ID: NOAA-NMFS-2012-0104). We have prepared final responses to the frequent substantive public comments received on the 2015 DEIS as well as on the SDEIS and include them here in Appendix C. After careful review of all comments received on the DEIS and SDEIS as well as the ALJ's Recommended Decision and associated public comments, NMFS has selected Alternative 7 as the Preferred Alternative.

1.5 Public Involvement

1.5.1 Scoping Process

Prior to publishing the notice of withdrawal and intent to prepare a new EIS, we had conducted NMFS internal scoping in January and April 2012 to determine the most applicable approach to review under NEPA. We reviewed the resources and alternatives addressed in the 2008 DEIS and determined that most information was still applicable, some resources of the human environment could be eliminated from a new analysis (because updated information indicated that impacts were nonexistent or negligible), and at least one environmental resource (consideration of gray whales from the WNP) should be added to the new analyses. We also determined it was

appropriate to terminate the 2008 DEIS and begin developing a new EIS that would include additional public scoping. We determined that doing so would be the best means to provide updated, high quality information to the public and to provide for related public involvement that would create a concise, current, and understandable record on the action and subsequent agency decision. With the announcement of our intention to prepare a new DEIS in the Federal Register (77 FR 29967, May 21, 2012), we opened a public scoping period and invited public comment.

Scoping is an open process that agencies must conduct under NEPA to determine the range and significance of the issues to be analyzed in depth in an EIS. As part of the scoping process, agencies invite the participation of affected federal, state, and local agencies, Indian tribes, the proponent of the action, and other interested persons, all of whom help to identify relevant issues to address in the EIS, while helping the agency eliminate insignificant issues from detailed study. Scoping can also help determine the level of analysis and types of data needed.

The public comment period for preparation of the new EIS was open from May 21 until August 10, 2012. We received 11 comment letters and addressed them in a separate scoping report (NMFS 2015b; refer to Appendix F). During internal NMFS and public scoping, we considered several sources of information to identify issues addressed in this FEIS, including but not limited to:

- The Makah Tribe's request;
- Public comment during scoping for the 2008 DEIS;
- The 2008 DEIS;
- Public comment on the 2008 DEIS;
- Public comment during scoping in 2012;
- Input from other federal agencies (including the Bureau of Indian Affairs as NMFS' cooperating agency);
- IWC documents and deliberations;
- The MMPA and its regulations;
- The WCA and its regulations;
- The Council on Environmental Quality's National Environmental Policy Act (NEPA) regulations (40 CFR 1500-1508);
- Other applicable statutes and regulations;
- Other environmental reviews under NEPA;
- Biological opinions under the ESA;
- NMFS' stock assessment reports and other MMPA-related documents;

- The Treaty of Neah Bay;
- The federal trust responsibility.

Following the publication of the 2015 DEIS, new circumstances and information presented at the 2019 ALJ hearing led NMFS to conduct a second internal scoping process in January 2020 to determine if supplementing the 2015 DEIS was appropriate. We concluded that the declaration of a UME for ENP gray whales warranted the development of an SDEIS. Public comments received on the 2015 DEIS and consultation with the Makah Tribe following its publication also led us to formulate a seventh, "composite" alternative using various elements of the five DEIS action alternatives. Although the formulation of this alternative itself did not warrant the development of the SDEIS, we determined during scoping that it may be beneficial to include the composite alternative in the SDEIS as well.

1.5.2 Concerns Identified During Scoping

The following concerns were identified during scoping. Detailed discussion of many of these concerns occurs throughout this document. Section 2, Alternatives, identifies and addresses concerns raised regarding alternatives analyzed and Appendix F summarizes our responses to comments raised during the 2012 scoping process.

1.5.2.1 Marine Habitat and Species

- Potential effects on marine habitat (such as kelp beds, surfgrass, intertidal area, or other habitat features).
- Potential effects of removing whales from the ecosystem.

1.5.2.2 Gray Whales

- Potential effects on the ENP gray whale population of removing individual whales in the action area by hunting.
- Threats to ENP gray whales throughout their range, including the UME declared in 2019
- Potential effects on PCFG whales.
- Potential effects on gray whale presence in the Makah U&A as a result of removing individual whales from the action area or from disturbing or frightening the whales in connection with hunting activities.
- Potential effects on individual gray whales from specific hunting methods.
- Potential effects on WNP whales that may be present in the action area during a hunt.

1.5.2.3 Other Wildlife Species

- Potential effects on wildlife of noise.
- Potential effects on wildlife of visual disturbance.
- Potential effects on wildlife from fuel/contaminant spills.
- Potential direct effects on wildlife from unintentionally striking animals with vessels or weapons.
- Potential indirect effects on marine wildlife resulting from changes in prey availability because of the removal or redistribution of gray whales.

1.5.2.4 Economics

- Potential economic effects on land-based, tourism-related businesses.
- Short-term effects of tourism increase or decrease related to whale hunts.
- Negative economic effect on the Tribe.
- Long-term effects of whale hunting on county-wide and state-wide tourism.
- Potential economic effects on water-dependent businesses.
- Effects on Pacific coast whale-watching industry.
- Effects on government spending.
- Effects on international shipping and local commercial and recreational fisheries.

1.5.2.5 Environmental Justice

- Potential disproportionate socioeconomic (employment and income) effects on minority and low-income populations.
- Potential disproportionate sociological effects on minority and low-income populations.

1.5.2.6 Social Environment

- Potential effects on attitudes and emotions, including spiritual beliefs.
- Potential effects on human relations.

1.5.2.7 Cultural Resources

- Potential effects on archaeological and historical sites or traditional cultural properties in the action area.

1.5.2.8 Ceremonial and Subsistence Resources

- Potential effects on Makah ceremonial and subsistence practices from resuming whaling.
- Potential effects on Makah ceremonial and subsistence practices from not being allowed to resume whaling.

1.5.2.9 Noise

- Disturbance to human visitors in the immediate vicinity of hunting activities.
- Disturbance to onshore communities or homes on the Makah Reservation.

1.5.2.10 Aesthetics

- Visual effects on on-scene observers of the hunt.
- Visual effects on off-site observers of the hunt through the media.

1.5.2.11 Transportation

- Potential for the hunt and related activities to interfere with normal marine vessel traffic.
- Potential for the hunt and related activities to interfere with normal aircraft traffic.
- Potential for the hunt and related activities to interfere with normal highway traffic.
- Potential for hunt and related traffic to cause accidents or disrupt essential emergency services transit.

1.5.2.12 Public Services

- Potential for hunt-related activities to result in injuries or other emergency incidents that exceed the capacities of tribal and other local public health facilities.
- Potential for hunt-related activities to affect and potentially overwhelm tribal, county, and Coast Guard law enforcement personnel and facilities.
- Potential for hunt-related activities to detract from enforcement needed in other areas.

1.5.2.13 Public Safety

- Potential effects on public and hunter safety related to possible methods of killing whales.
- Potential effects on public and hunter safety from wounded whales.
- Potential effects on public and hunter safety of prevailing weather and sea conditions.
- Potential effects on public and hunter safety related to protest activities and conflicts.

1.5.2.14 Human Health

- Potential positive health effects on tribal members and others consuming any whale products.
- Potential negative effects from ingesting potential contaminants contained in freshly harvested and drift whale products.

1.5.2.15 Concerns not Specifically Related to a Resource Area

- Precedential effect on the MMPA if take moratorium is waived (e.g., Would other tribes or organizations be able to obtain waivers more easily?).
- Precedential effect on whaling world-wide if a Makah hunt is authorized.
- Effect on the Makah and other tribes associated with upholding or denying treaty rights.
- International effect on the United States' position in international forums of denying an ethnic minority a subsistence right secured in a treaty.
- Effect on management of special areas (such as the Olympic Coast National Marine Sanctuary or designated wilderness areas or marine sanctuary).
- The Makah Tribe's eligibility for an aboriginal subsistence whaling quota.

1.5.3 Comments on the DEIS and SDEIS

As described above, NMFS published a Draft Environmental Impact Statement (DEIS) on March 13, 2015 and received public comments through July 31, 2015 via email, mail, fax, and submissions to www.regulations.gov (Docket ID: NOAA-NMFS-2012-0104). We also held two public meetings in April 2015 to receive comments in person. We received more than 57,000 comments over the course of the 140-day comment period. Over 99% of comments were submitted as form letters. NMFS West Coast Region provided draft responses to comments on the 2015 DEIS in November 2019 as part of the record for the hearing before the Administrative Law Judge which were incorporated into the FEIS. These responses were developed with the best available information at that time. We have included the 2019 responses to comments as Appendices E and F.

We published a Supplemental DEIS (SDEIS) on July 1, 2022 and received public comments until October 14, 2022. The public comment period was then briefly reopened from October 28 through November 3, 2022. We received 47 comments via email, mail, and submissions to www.regulations.gov (Docket ID: NOAA-NMFS-2012-0104). Commenters on the DEIS and SDEIS included state and federal entities, nonprofit organizations, and interested individuals from

the United States and around the world. Appendix C summarizes the comments received on the SDEIS. After carefully reviewing the comments received on the DEIS and SDEIS, we have updated the analysis in the FEIS to include the most recent information available and updated our analysis where necessary. We have also included responses to frequent and substantive comments received on the DEIS and SDEIS in Appendix C.

1.6 Relationship to Other Treaties, Laws, Regulations, Policies, and Processes

Various authorities — both international and national (federal, state, and local) treaties, laws, regulations, policies, and processes — may apply to the whale hunting activities proposed by the Makah Tribe. While some of these authorities require specific agency action before any hunt, such as promulgation of regulations and issuance of permits, others require agency review and consultation. Table 1-2 lists those authorities that are most relevant to the Makah Tribe's proposed whale hunting.

Table 1-2. International, national, state, and tribal treaties, laws, regulations, policies, and processes that may be required for Makah whaling.

Authority	Delegated Oversight Body	Description of Authority, Necessary Action, or Review/Consultation
IWC Schedule, Paragraph 13 (Aboriginal Subsistence Whaling Catch Limits)	IWC and United States government	Sets catch limits by whale stock based on requests from contracting governments acting on behalf of aborigines (and informed by scientific advice). United States has submitted requests on behalf of the Makah, most recently in 2018, to renew catch limits from 2019 through 2025.The IWC approved this catch limit. In 2024, the catch limits will be renewed for a 6-year period in accordance with the Scientific Committee's advice.
Treaty of Neah Bay	United States government and NMFS	Establishes fishing, whaling, and sealing rights for the Makah. United States and NMFS must decide how best to meet their federal trust responsibilities when making decisions about the Makah tribe's request to whale
MMPA	NMFS	Prohibits the take of marine mammals, subject to a waiver of the moratorium and/or compliance with a statutory exemption. Consistent with the 9th Circuit decision in *Anderson v. Evans* (2004) and in response to the Makah tribe's request to whale, NMFS has proposed to waive the moratorium on take for the Makah's requested whale hunting, and proceeded through formal rulemaking (including an on-the record hearing). NMFS will make a final decision about whether to issue a waiver and issue final regulations. In addition, if NMFS issues a waiver and final regulations, a hunt may require incidental take authorization under the MMPA for any other marine mammals that could be incidentally taken.
WCA	NMFS	Implements United States obligations under the ICRW. NMFS must decide whether to enter into a cooperative agreement with the Makah Tribe for co-management of the gray whale hunts and whether to publish an aboriginal subsistence whaling quota for the Makah's use.
NEPA	Council on Environmental Quality / EPA and NMFS	Requires that an EIS be prepared for every major federal action with the potential to significantly affect the quality of the human environment. Consistent with the 9th Circuit decision in *Anderson v. Evans,* NMFS is preparing this EIS and will eventually issue a ROD. NMFS previously prepared a DEIS in 2015 and a SDEIS in 2022.
ESA	USFWS/NMFS	Requires federal agencies to consult with the FWS or NMFS (depending on species jurisdiction) to ensure that activities authorized, funded, or carried out by federal agencies are not likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of designated critical habitat. NMFS has consulted internally and with FWS for the ESA-listed species and designated critical habitat in the action area.
Magnuson-Stevens Act	NMFS	Requires federal agencies to consult with NMFS with respect to any action authorized, funded, or undertaken (or proposed to be the same) when the action may adversely affect any essential fish habitat. NMFS has consulted internally on the effects of the proposed action to essential fish habitat in the action area.

Table 1-2. International, national, state, and tribal treaties, laws, regulations, policies, and processes that may be required for Makah whaling.

Authority	Delegated Oversight Body	Description of Authority, Necessary Action, or Review/Consultation
National Marine Sanctuary Act	NOAA National Ocean Service, National Marine Sanctuaries Program	Requires federal agencies to consult with NOAA when a proposed action internal or external to any sanctuary is likely to destroy, cause the loss of, or injure a sanctuary resource. NMFS has and will continue to consult with Sanctuary staff.
Coastal Zone Management Act	Washington Department of Ecology (Ecology)	Requires federal agencies to ensure that activities carried out in or outside the state's coastal zone are consistent with the enforceable policies of approved state management plans, to the maximum extent practicable. NMFS has consulted with Ecology.
Migratory Bird Treaty Act and Executive Order 13186 (Migratory Birds)	FWS	Prohibits intentional and unintentional take of migratory birds.
Executive Order 12898 (Environmental Justice)	EPA	Provides for fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. This FEIS assesses the affected environment as it pertains to environmental justice, as well as the effects to environmental justice from the proposed action and its alternatives.
Executive Order 12996 (Management and General Public Use of the National Wildlife Refuge System)	Department of Interior	Establishes the mission of the National Wildlife Refuge System and guiding principles for the management and general public use of refuges. This FEIS assesses the affected environment as it pertains to the Washington Islands National Wildlife Refuges, as well as the effects to the Washington Islands National Wildlife Refuges from the proposed action and its alternatives.
Executive Order 13175 (Consultation and Coordination with Indian Tribal Governments) and NOAA Administrative Order 218-8 (Policy on Government-to-Government Consultation with Federally Recognized Indian Tribes and Alaska Native Corporations)	DOC/NOAA	Requires federal agencies to establish regular and meaningful consultation and collaboration with tribal officials in the development of Federal policies that have tribal implications, to strengthen the United States government-to-government relationships with Indian tribes, and to reduce the imposition of unfunded mandates upon Indian tribes.
National Historic Preservation Act	Washington State Historic Preservation Officer (SHPO) and Tribal Historic Preservation Officer (THPO)	Requires federal agencies to consider cultural resources as part of all licensing, permitting, and funding decisions when the proposed action may have an effect on properties included in or eligible for the National Register of Historic Places. NMFS has assessed the potential impacts on registered historic sites in the action area and concluded that consultation is not necessary.

Table 1-2. International, national, state, and tribal treaties, laws, regulations, policies, and processes that may be required for Makah whaling.

Authority	**Delegated Oversight Body**	**Description of Authority, Necessary Action, or Review/Consultation**
Clean Water Act	EPA; Washington Department of Ecology, and Makah Tribal Council	Establishes standards and regulations by which waters of the state must be managed. NMFS provided the 2015 draft EIS to Ecology for its review.
Makah Whaling Permit	Makah Tribal Council and Makah Whaling Commission	Reviews whaling crew qualifications, identifies whaling crew and vessel participation, and provides other hunt restrictions. The Makah Tribal Council would issue the permit(s) to a whaling captain(s) before any hunt, based on recommendations from the Makah Whaling Commission.

1.7 Organization of this EIS

This EIS is organized in the following categories and sections:

- Executive Summary
- Acronyms and Abbreviations
- Glossary
- Table of Contents
- Section 1, Purpose and Need
- Section 2, Alternatives
- Section 3, Affected Environment
- Section 4, Environmental Consequences
- Section 5, Cumulative Effects
- References
- Distribution List
- List of Preparers and Agencies Consulted
- Index
- Appendices

Section 2

Alternatives

Table of Contents

List of Tables

2.0 ALTERNATIVES

2.1 Introduction

This section describes and compares the alternatives under consideration, including the Makah Tribe's proposed action. Figure 1-1 in Chapter 1 provides a map of the Tribe's U&A and the area within the U&A where the Tribe proposes to hunt gray whales. Subsection 2.2 describes our process for formulating alternatives. Subsection 2.3 describes the alternatives analyzed in detail in this FEIS. Subsection 2.4 describes alternatives we considered but eliminated from detailed analysis.

2.2 Alternative Development Process

We received the Makah's request for a waiver of the MMPA take moratorium in February of 2005. After reviewing the request, we concluded it contained relevant and appropriate information to warrant proceeding with a full evaluation. We completed an internal NMFS and public scoping process, identified alternatives, and released a DEIS in May of 2008 (NMFS 2008a). Besides the No-action Alternative and an alternative that reflected the Tribe's proposal, we evaluated four other alternatives that included variations on the area and timing of a hunt, and the limits on ENP and PCFG whales. We also described eight alternatives that we considered but did not evaluate in detail. We received a number of comments on the 2008 DEIS, including comments on the alternatives and have summarized our consideration of them in a NMFS memorandum (NMFS 2015a).

Subsequent to publishing the 2008 DEIS, we received new information that led us to terminate that process and begin the current EIS process (Subsection 1.4.3, Other Environmental Assessments and Court Decisions Informing this Action). Subsection 1.5, Scoping and the Relevant Issues, describes the issues developed during the 2012 and 2020 scoping processes. From the 2012 scoping process, we developed four action alternatives to analyze alongside the Tribe's proposed action and the No-action alternative. Key differences between the action alternatives include varying hunt parameters such as harvest limits, hunting seasons, and formulas used to manage impacts on PCFG gray whales. Upon reviewing public comments on the 2015 DEIS, additional information relevant to the Tribe's request, information presented during the 2019 hearing, and the ALJ's Recommended Decision, we developed an additional action alternative entirely composed of elements from other alternatives already analyzed in the 2015 DEIS. This "composite" alternative served as the basis of the proposed rule published by NMFS

in 2019 (see Subsection 1.1, Introduction) and was analyzed in the 2022 supplemental DEIS for reasons described in Subsection 1.5.1, Scoping Process.

The Council on Environmental Quality's regulations require that an agency consider and assess the environmental consequences of a No-action Alternative, the proposed action alternative, and other reasonable alternatives. Reasonable alternatives, along with the proposed action and the No-action Alternative, must be rigorously explored and objectively evaluated in the EIS and presented in comparative form to define the issues and provide the decision-maker with a clear basis for choice among the options. An agency preparing an EIS must, therefore, make a threshold determination of reasonableness when selecting alternatives from those identified during internal and public scoping. Alternatives that meet the reasonableness threshold are analyzed in detail in the EIS, while alternatives that do not meet this threshold are eliminated from detailed study.

In developing the full range of action alternatives, we considered the principal components associated with a hunt (area, timing, and limits on striking and harvesting whales), as well as regulatory components of a hunt.

To assess the reasonableness of an alternative, we considered the potential of the alternative to meet the purpose and need of NMFS' proposed action. Subsection 1.3, Purpose and Need for Action, describes these as:

> Purpose for Action - NMFS' purpose is to implement the laws and treaties that apply to the Tribe's request, including the Treaty of Neah Bay, the MMPA, and the WCA. The Makah Tribe's purpose is to resume its traditional hunting of gray whales under its treaty right.
>
> Need for Action - NMFS' need for this action is to implement its federal trust responsibilities to the Makah Tribe with respect to the Tribe's reserved whaling rights under the Treaty of Neah Bay, and to comply with the requirements of the MMPA and the WCA. Under the MMPA, we must protect and conserve gray whale populations; under the WCA, we must regulate whaling in accordance with the ICRW and IWC regulations. The Makah Tribe's need for the action is to exercise its treaty whaling rights to provide a traditional subsistence resource to the community and to sustain and revitalize the ceremonial, cultural, and social aspects of its whaling traditions.

We also considered factors such as consistency with applicable law, practicability and feasibility, and the extent to which an alternative would identify and illuminate potential impacts or key concerns identified during scoping (Subsection 1.5.2, Concerns Identified During Scoping).

Subsection 2.3, Alternatives Considered for Detailed Study, describes the alternatives studied in detail in this FEIS. Additional information about our assumptions and expectations regarding each alternative is discussed in Chapter 4, where we analyze the impacts of each alternative. Those alternatives we considered but eliminated from detailed study are described in Subsection 2.4, Alternatives Considered but Eliminated from Detailed Analysis.

2.3 Alternatives Considered for Detailed Study

This FEIS analyzes seven alternatives in detail—a No-action Alternative and six action alternatives, including a preferred alternative. The six action alternatives would allow the Makah Tribe to conduct limited ceremonial and subsistence hunting of ENP gray whales. One of the action alternatives (Alternative 2) reflects the Tribe's proposal. Alternative 3 (Offshore Hunt) differs from the Tribe's proposal in the area where hunting would be allowed and in the approach to managing impacts to the PCFG. Alternatives 4 (Summer/Fall Hunt) and 5 (Split-Season Hunt) have a different hunting season than the Tribe proposed, with the intention of avoiding impacts to WNP whales, and also have a different approach to managing impacts to the PCFG. Alternative 6 (Different Limits on Strikes and PCFG Mortality, and Limited Duration of Regulations and Permits) would have the same time and area as the Tribe's proposal, but a lower limit on strikes, a different approach to managing impacts to the PCFG, regulations that terminate in 10 years, and a limit of 3 years for permits. Alternative 7 (Composite- Preferred) combines various elements of the other five action alternatives to meet the goals of limiting the likelihood that tribal hunters would strike or otherwise harm a WNP gray whale and of ensuring that hunting does not reduce PCFG abundance below recent stable levels. Table 2-1 compares the key elements of the seven alternatives.

All action alternatives would include the following elements:

- MMPA waiver, regulations, and any necessary permits;
- WCA quota publication and execution of a cooperative agreement;
- Hunting of ENP gray whales only (no other marine mammal would be targeted);
- No hunting of a whale calf or whale accompanied by a calf;
- Restrictions on ENP gray whale product use and distribution;
- Public safety measures and enforcement;
- Training, certification, and permit process for tribal whalers and whaling captain;

- Makah Fisheries Management and NMFS hunt observers;
- Tribal enforcement of tribal whaling ordinance, NMFS enforcement of federal regulations;
- Monitoring of the hunt with adjustments for adaptive management;
- Ongoing gray whale management and monitoring at the national and international levels;
- Method of hunt.

2.3.1 Alternative 1 (No Action)

The No-action Alternative would result in no authorized hunting of gray whales by the Makah Tribe. We would not waive the MMPA take moratorium, promulgate regulations, issue permits, publish a quota for the Makah under the WCA, or enter into a cooperative management agreement with the Makah Tribe for gray whale hunts. The IWC catch limit of 980 whales for the 7-year period beginning in 2019 would not change if we were to adopt the No-action Alternative. Under the No-action Alternative, no part of the catch limit would be allocated to the Makah Tribe, so the entire catch limit would be available for harvest by the Chukotka Natives. Examining the No-action Alternative will provide the public and NMFS with information about the following:

- Cultural and social impacts on the Makah Tribe if tribal members are unable to exercise their treaty right to hunt whales in the Tribe's U&A.
- Conservation impacts on gray whales and the local marine ecosystem if no ENP gray whales are hunted in the action area.
- Social effects from no hunting, including economics, public safety, aesthetics, and public sentiment regarding whales.
- Tourism/whale-watching effects if no ENP gray whales are hunted in the action area.

Table 2-1. Primary Differences Among Alternatives.

Alternatives								
Whale Hunting Components		**1 No-action**	**2 Tribe's Proposed Action**	**3 Offshore Hunt**	**4 Summer/Fall Hunt**	**5 Split Season Hunt**	**6 Different Limits on Strikes and PCFG, and Limited Duration of Regulations and Permits**	**7 Composite – Preferred**
Hunt timing		None	December 1 through May 31	Same as Alternative 2	June 1 through November 30	December 1 through December 21; May 10 through May 31	Same as Alternatives 2 and 3	Summer/fall hunts and hunting approaches will be authorized from July 1 through October 31, and winter/spring hunts and hunting approaches will be authorized from December 1 through May 31. Only one hunt season may be authorized in a calendar year, however the first month (December) of a winter/spring hunt would fall in the same calendar year as a summer/fall hunt.
Hunt area		None	U&A west of Bonilla-Tatoosh line; no whale may be struck within 200 yards (183 m) of Tatoosh Island or White Rock during the month of May	Same as Alternative 2, except at least 5 miles (8 km) from shore	Same as Alternative 2, except no whale may be struck within 200 yards (183 m) of Tatoosh Island or White Rock during any month	Same as Alternative 2	Same as Alternatives 2 and 5	U&A west of Bonilla-Tatoosh Line, with other site and time restrictions possible to protect Olympic Coast National Marine Sanctuary resources
Maximum limit for harvested, struck, and struck and lost whales	Annual	0	Up to 5 harvested, 7 struck, and 3 struck and lost	Up to 5 harvested, 6 struck, and 2 struck and lost	Up to 5 harvested, 7 struck, and 3 struck and lost; harvest, struck, and struck and lost limited by PCFG limit (see below)	Up to 5 harvested; struck and struck and lost limited by PCFG limit (see below)	Up to 4 harvested (7 over 2 years); up to 4 struck (7 over 2 years); struck and lost limited by strike limit or PCFG limit (see below)	In winter/spring hunts, up to 3 harvested, struck, or struck and lost. In summer/fall hunts, only 1 harvested and 2 struck or struck and lost
	6-year	0	Up to 24 harvested, 42 struck, and 18 struck and lost	Up to 24 harvested, 36 struck, and 12 struck and lost	Up to 24 harvested, 42 struck, and 18 struck and lost; harvest, struck, and struck and lost limited by PCFG limit (see below)	Up to 24 harvested; struck and struck and lost limited by PCFG limit (see below)	Up to 21 harvested, 21 struck; struck and lost limit dictated by PCFG limit (see below)	Up to 12 harvested, and 15 struck or struck and lost
	10-year	0	Up to 40 harvested, 70 struck, and 30 struck and lost	Up to 40 harvested, 60 struck, and 20 struck and lost	Up to 40 harvested, 70 struck, and 30 struck and lost; harvest, struck, and struck and lost limited by PCFG limit (see below)	Up to 40 harvested; struck and struck and lost limited by PCFG limit (see below)	Up to 35 harvested, 35 struck; struck and lost limited by PCFG limit (see below)	Up to 20 harvested, and 25 struck, or struck and lost

ENP Population Abundance Threshold	N/A	N/A	N/A	N/A	N/A	N/A	The impacts of the Preferred Alternative are analyzed without an ENP population abundance threshold. However, three thresholds are considered as Sub-alternatives. Under the Sub-alternatives, hunting would cease if the abundance estimate (N) of the ENP gray whale stock dropped below: a) N=11,000, b) N=16,000, or c) N=18,000
Additional limits on harvest or mortality of PCFG whales. Estimated limits are based on current conditions and could change based on updated information. The descriptions in the table are summaries. Please refer to the narrative for full details, and Subsection 3.4.2.1.3, for background on the potential biological removal (PBR) approach.	N/A	Tribe's bycatch proposal (apply PBR-based formula, with Rmax of 4% and Recovery Factor same as for ENP (1.0) and Nmin of OR-SVI) results in about 3.0 whales/year; struck but not landed do not count as PCFG; no carry-over of unused limit	Total mortality limit set at PBR (as reported in NMFS' stock assessment report); additional female mortality limit set based on proportion of females in PCFG (results in about 2.7 males and 1.6 females); all struck but not landed count as PCFG whales in proportion to presence of PCFG whales; no carry-over of unused limit	Mortality limit set to achieve or maintain 80% of carrying capacity (PBR-based formula with recovery factor of 0.35), minus other human-caused mortality (results in 1 whale); approach only known ENP males; all strikes count as PCFG; no carry-over of unused limit unless it's between 0.5 and 1.0	Mortality limit set at 10% of PBR (results in about 1 whale/4 years); struck but not landed count as PCFG in proportion to presence of PCFG whales; carry-over of unused limit used to calculate hunt hiatus	Mortality limit set at PBR minus other human-caused mortality (results in about 2 whales/year); all struck but not landed count as PCFG in proportion to presence of PCFG whales; no carry-over of unused limit	Mortality limit set at 16 PCFG whales over 10 years, no more than 8 of which may be females. Hunting would be prohibited if the forecasted abundance of the PCFG falls below 192 whales, or the minimum abundance falls below 171 whales
Waiver and permit duration and additional regulations	N/A	Unlimited waiver period; permits for maximum of 5 years; no additional regulations	Same as Alternative 2	Same as Alternatives 2 and 3	Same as Alternatives 2, 3, and 4	Waiver period ends after 10 years; permits for maximum of 3 years	Waiver period ends after 10 years; initial permit for maximum of 3 years followed by permits up to 5 years

2.3.2 Alternative 2 (Tribe's Proposed Action)

This description of the Makah Tribe's proposed action is based on the Tribe's February 2005 MMPA waiver request. In its request the Tribe referred to a whale management plan adopted in 1998 and revised in 2001 to govern future proposed whale hunts. The Tribe's waiver request includes a proposal that NMFS issue regulations with provisions similar to those contained in the 2001 Gray Whale Management Plan. In addition, in 2013 the Tribal Council adopted an ordinance governing whaling by tribal members. This ordinance supersedes all prior management plans. The waiver request and the 2001 management plan are provided as Appendix A to this FEIS. The Tribe's 2013 whaling ordinance is provided as Appendix B. In its MMPA waiver request, the Tribe proposed to abide by the specific conditions described below.

In the following description of Alternative 2, several elements would be common to all of the action alternatives. We indicate these with the parenthetical phrase "Common among Action Alternatives."

2.3.2.1 Regulatory Actions Requested of NMFS (Common among Action Alternatives)

The Makah Tribe requested authorization to hunt ENP gray whales in the coastal portion of its U&A (that is, excluding the Strait of Juan de Fuca) (Figure 1-1). Whaling is a right expressly secured in the 1855 Treaty of Neah Bay. Pursuant to the court's decision in *Anderson v. Evans* (2004), to hunt whales, the Makah Tribe seeks domestic authorization from NMFS under two statutory authorities—the MMPA and the WCA.

Specifically, we would have to authorize any Makah whaling by (1) waiving the moratorium prohibiting take of marine mammals under subsection 101(a)(3)(A) of the MMPA with respect to ENP gray whales, (2) promulgating regulations to implement the waiver and govern the hunts in accordance with subsection 103 of the MMPA, (3) issuing any necessary permits to the Makah under subsection 104 of the MMPA and the hunt regulations, and (4) entering into a cooperative agreement for co-management of the hunt and publishing any relevant aboriginal subsistence whaling quotas under the provisions of the WCA (see Subsection 1.2.3, Marine Mammal Protection Act, and Subsection 1.2.4, Whaling Convention Act, for a discussion of those statutes).

2.3.2.2 Gray Whale Hunt Details

2.3.2.2.1 Species (Common among Action Alternatives)

The Makah Tribe requested a waiver of the take moratorium for ENP gray whales only. As noted in Subsection 1.1.3, Summary of Gray Whale Status, we currently do not recognize the PCFG as a separate stock but have stated that it "appears to be a distinct feeding aggregation and may one

day warrant consideration as a distinct stock" (Carretta et al. 2023). The Tribe's request included separate consideration for PCFG whales but did not request a waiver of the take moratorium for PCFG whales (as they were not designated as a separate population stock at the time of the request). Other marine mammals occur in the Makah U&A, including WNP gray whales, which could be present during January through May (Subsection 1.1.3, Summary of Gray Whale Status; Subsection 3.4.3.2, Western North Pacific Gray Whales). The Tribe has not requested a waiver of the take moratorium for WNP whales. No other species are included in the Tribe's waiver request; thus, the FEIS does not analyze their intentional take (though it does consider the potential that other species could be affected by a hunt for gray whales). These entities are defined as follows:

Western North Pacific (WNP) gray whales = Gray whales that feed during the summer and fall in the Okhotsk Sea (primarily off northeast Sakhalin Island, Russia), some of which also feed off southeastern Kamchatka in the Bering Sea. WNP gray whales are considered a population stock under the MMPA, and the stock is designated as depleted. WNP gray whales are recognized as a distinct population segment (DPS) under the ESA and are designated as endangered.

Eastern North Pacific (ENP) gray whales = Gray whales that feed during the summer and fall primarily in the Chukchi, Beaufort, and northwestern Bering Seas, but also as far south as California. ENP gray whales are considered a population stock under the MMPA. ENP gray whales were formerly listed as an endangered species under the ESA but subsequently recovered and were delisted in 1994 (59 FR 31094, June 16, 1994).

PCFG whales = Gray whales observed in at least 2 years between June 1 and November 30 in the PCFG area (along the U.S. and Canada coasts between 41°N and 52°N, excluding areas in Puget Sound) and entered into the Cascadia Research Collective's photo-identification catalog. For purposes of determining whether a harvested whale is a PCFG whale and therefore counts against a bycatch or mortality limit, the Tribe's proposal under Alternative 2 would include cataloged whales seen in at least 1 year, while the other action alternatives would include cataloged whales seen in 2 or more years. Alternative 7, the preferred alternative, would assume any whale struck, struck and lost, or approached during the summer hunt time period to be a PCFG whale. Under the MMPA, PCFG whales are considered part of the ENP gray whale population stock and have been described in the ENP gray whale SARs as a feeding aggregation.

2.3.2.2.2 Numbers of Whales Harvested (Annual and 6-year)

The Tribe proposes no more than five whales to be harvested in any calendar year and no more than 24 whales in any 6-year period, consistent with the catch limit set by the IWC. (The Tribe

originally requested a 5-year limit of 20 whales, consistent with the IWC limit at the time of the original request. The IWC now sets 6-year rather than 5-year catch limits (with the exception of the current one-time 7-year catch limit, see Subsections 1.2.4.1.3, IWC Aboriginal Subsistence Whaling and 1.4.1.2.2, Overview of Requests for ENP Gray Whales on Behalf of the Makah); thus, this FEIS analyzes the 6-year limit.)

We use the term "harvest" in this FEIS to mean killing and landing a whale (Subsection 1.1.1, Summary of the Proposed Action). IWC regulations, which set 'catch limits' for ASW, count all "takes" as "catches" and define "take" as "to flag, buoy, or make fast to a whale catcher" (IWC 2022a). In contrast, the MMPA defines take as to "harass, hunt, capture, or kill, or attempt to harass, hunt, capture, or kill" (16 USC 1362(13)). Many whale hunting activities that the Makah propose (i.e., pursuing, approaching, striking, and killing) are "takes" under the MMPA but not the IWC regulations (for example, pursuing and approaching a whale are not activities expressly noted in the IWC regulations).

The Tribe also proposes to limit the number of harvested whales further, if necessary to meet international treaty obligations of the United States under the ICRW, or to prevent the abundance of the ENP gray whale stock from falling below its OSP level (Subsection 3.4.2.1, Marine Mammal Protection Act Management, explains the OSP concept).

2.3.2.2.3 Limits on Harvesting PCFG Whales

The Makah Tribe's proposed action contains two conservation measures related to PCFG whales "to ensure that gray whales remain a functioning element of the ecosystem" (Makah Tribe 2005). The measures would (1) restrict the time and area of any hunt to reduce the likelihood that a PCFG whale would be killed (discussed in Subsection 2.3.2.2.8, Location of Hunt (Area Restrictions), and Subsection 2.3.2.2.9, Timing of Hunt (Seasonal Restrictions)) and (2) cease the hunt if a predetermined number of PCFG whales were landed and identified. The Tribe refers to this limit on PCFG whales as an "allowable bycatch limit." Here, we use the term "allowable bycatch limit" to refer to the Tribe's proposed limit on landed and identified PCFG whales. In contrast, other alternatives focus on all hunt-related mortality (whales that are struck and lost as well as whales that are landed) and use the term "PCFG mortality limit" to refer to limits on all hunt-related PCFG mortality, whether the whale is landed or not.

The Makah Tribe's waiver request states that the Makah Fisheries Management observers (Subsection 2.3.3.2.7, Other Environmental Protection Measures, Makah Fisheries Management Department and NMFS Observers and Monitoring) would photograph any whale landed and

provide the photographs to NMFS to compare with the PCFG photographic database.[7] This would allow NMFS and the Tribe to determine if any landed whale were a PCFG whale.

Under the Tribe's proposal, whales struck but not landed would not count against the allowable bycatch limit of PCFG whales. The Tribe proposes to stop hunting when a predetermined number of cataloged whales (sighted at least once in the PCFG range from June 1 through November 30) are landed. That number would be established using a formula based on the one NMFS uses to set the level of human-caused mortality that allows marine mammal population stocks to achieve or maintain their OSP level. That formula contains three parameters: (1) maximum net productivity rate, (2) minimum abundance, and (3) a recovery factor. The MMPA refers to the result of this formula as the "potential biological removal" or PBR level (see Subsection 3.4.2.1.3, Linking Marine Mammal Population Parameters to Removals). Where we have sufficient information, we report PBR levels for each recognized marine mammal stock in our periodic stock assessment reports. We have also developed guidelines for determining the values in this formula in setting PBR (NMFS 2005b; see updated version NMFS 2023b). Subsection 3.4.2.1, Marine Mammal Protection Act Management, describes the formula in greater detail and the agency guidelines for its use.

To establish an allowable bycatch limit, the Tribe proposes to use a 4 percent maximum net productivity rate (consistent with the IWC analysis of the Tribe's hunt; Subsection 3.4.3.4.4, PCFG Status, Carrying Capacity, and Related Estimates, and Subsection 4.1.2.3, Potential Number of ENP and PCFG Whales Killed; Likelihood of Striking a WNP Whale; Likely Number of Whales Harvested) and the same recovery factor (currently 1.0) that NMFS uses to calculate PBR for the ENP stock as a whole. Instead of using the entire PCFG to set the minimum abundance value in the formula, however, the Tribe also proposes to use a subset of the PCFG, which is only those PCFG whales sighted from Oregon to Southern Vancouver Island. Under current conditions, the Tribe's proposed method would result in an allowable bycatch limit of about 3.0 PCFG whales per year (Subsection 4.1.2, Alternative 2, describes the application and result of the Tribe's proposed method).

There are a number of variations on how the basic formula described above could be used to set a PCFG mortality limit, depending on the management goal. For example, in our most recent stock

[7] Cascadia Research Collective currently manages the only available photographic database for ENP gray whales, and also has expertise to determine matches (Subsection 3.4.3.3.1, ENP Seasonal Distribution, Migration, and Movements). Any regulations adopted in conjunction with a waiver of the take moratorium should require NMFS to determine that adequate photo-identification catalogs and processes are in place prior to issuing a hunt permit.

assessment report for gray whales, we calculate a PBR level for the PCFG using a more recent maximum productivity value of 6.2 percent, different values for minimum abundance (based on abundance in the PCFG range from northern California to northern British Columbia), and a recovery factor of 0.5, which results in an informational PBR of 3.5 whales per year (Carretta et al. 2023). The action alternatives in this FEIS explore the effect of using various values for the parameters in the formula to set a PCFG mortality limit.

The Tribe proposes to count only those whales that are landed and photographically identified as PCFG whales. This method does not account for all PCFG whales potentially killed in a tribal hunt, however, because PCFG whales may be struck and killed but not landed and identified. Alternatives 3 through 7 explore different methods of setting a PCFG mortality limit and accounting for whales that are struck but not landed.

Finally, the Tribe does not propose to account for other sources of human-caused mortality when setting the allowable bycatch limit for PCFG whales. In its comments on the 2008 DEIS, the Marine Mammal Commission questioned this approach. Alternatives 4 and 6 therefore explore the effects of setting a PCFG mortality limit in a Makah hunt that takes into account other sources of human-caused mortality.

2.3.2.2.4 Number of Whales Struck (Annual and 6-year)

The Makah Tribe would limit the number of ENP gray whales that may be struck to no more than seven whales in any calendar year and no more than 42 whales in any 6-year period. Consistent with the IWC Schedule, the Tribe defines "strike" in their request as "any blow or blows delivered to a whale by a harpoon, rifle, or other weapon which may result in death to a whale, including harpoon blows if the harpoon is embedded in the whale, and rifle shots that hit a whale."

The IWC Schedule defines "strike" as meaning "to penetrate with a weapon used for whaling." The WCA implementing regulations define "strike" as "hitting a whale with a harpoon, lance, or explosive device" (50 CFR 230.2). Subsection 916k of the WCA provides that regulations of the IWC are "effective with respect to all persons and vessels subject to the jurisdiction of the United States." For purposes of analyzing the Tribe's request, we therefore interpret the WCA definition of "strike" to be consistent with the IWC Schedule. The Tribe also proposes to limit the number of whales struck to further meet the ICRW obligations of the United States, or to prevent the ENP gray whale stock abundance from falling below its OSP level.

2.3.2.2.5 Number of Whales Struck and Lost (Annual and 6-year)

Whales that are known to be struck, but not flagged, buoyed, or secured to the vessel, are considered to be "struck and lost." The Tribe proposes to restrict the number of struck and lost whales to no more than three whales in any calendar year and no more than 18 whales in any 6-year period. These numbers are included in the numbers for annual and 6-year proposed strikes (i.e., three struck and lost whales per year is part of the seven-whale strike limit per year, and not additive). If the struck and lost quota is met or exceeded, the Tribe proposes to stop hunting to allow the opportunity to reevaluate techniques and address potential problems.

2.3.2.2.6 Whales Approached and Subjected to Unsuccessful Strike Attempts

Whales not harvested or struck may nevertheless be disturbed by Makah hunters. In its request, the Tribe referred to its experience in 1999 and 2000 to estimate there would be four unsuccessful harpoon attempts for each successful strike, and 20 whales approached for each successful strike. Based on our review of the available data from the 1999 and 2000 hunts, and in particular the reports of the 1999 (Gosho 1999) and 2000 (Gearin and Gosho 2000) hunts, we have developed different estimates for this analysis.

The Tribe's request states that, based on experience with whale hunts in 1999 and 2000, there would be 10 approaches for each whale struck. The Tribe estimated that with 10 approaches for each whale struck there would be 20 whales approached, because of the average pod size of two whales, as observed during the southbound counts at Granite Canyon.

To estimate the potential number of unsuccessful harpoon attempts for the action alternatives, we considered the Tribe's hunt experience from both 1999 and 2000. In 1999, tribal hunters made three unsuccessful harpoon attempts and one successful strike. Based on this information, the Tribe's request concluded there would be four unsuccessful harpoon attempts for each successful strike. However, the actual ratio experienced in the 1999 hunt was 3:1, not 4:1, because the fourth attempt was successful. The Tribe also hunted in 2000 and made three unsuccessful harpoon attempts and no successful strikes. Thus, the ratio of unsuccessful harpoon attempts to successful strikes from the combined 1999 and 2000 hunting seasons would be 6:1. This is the ratio we use to estimate the number of unsuccessful harpoon attempts.

2.3.2.2.7 Age and Reproductive Status (Common among Action Alternatives)

The Tribe proposes to prohibit the striking of a whale calf or any whale accompanied by a calf. Gray whale calves generally accompany adult female parents during migration and may be observed as pairs of traveling whales.

2.3.2.2.8 Location of Hunt (Area Restrictions)

The area where the Makah Tribe proposes to hunt is confined to its U&A west of the Bonilla-Tatoosh line, excluding the Strait of Juan de Fuca. WAC 220-16-490 defines the Bonilla-Tatoosh Line as a line projected from the most westerly point on Cape Flattery to the lighthouse on Tatoosh Island, then to the buoy adjacent to Duntz Rock, then to Bonilla Point on Vancouver Island. The Tribe's U&A, as adjudicated in *United States v. Washington* (1974 and 1985), also excludes grounds that the Makah historically hunted and fished, but that are now beyond the exclusive economic zone (EEZ), which is also the boundary between Canada and the United States. According to the Tribe's waiver request, restricting the hunt to the area of its U&A outside the Strait of Juan de Fuca, in conjunction with the proposed seasonal restrictions (Subsection 2.3.2.2.9, Timing of Hunt (Seasonal Restrictions)), is designed to minimize the potential for killing PCFG whales. Also, to address concerns about impacts to nesting seabirds, under the Tribe's proposal no whale may be struck within 200 yards (183 meters) of Tatoosh Island or White Rock during the month of May. Alternative 4 (Summer/Fall Hunt) would have the same 200-yard (183-meter) provision, but it would apply to all months. Alternative 3 (Offshore Hunt) would differ from all other action alternatives by constraining the hunt location to areas farther than 5 miles (8 km) offshore of the Tribe's U&A area outside the Strait of Juan de Fuca. Under Alternative 7 (Preferred) other sites could be subject to hunt restrictions via the hunt permitting process to protect Olympic Coast National Marine Sanctuary resources pursuant to consultation under the National Marine Sanctuary Act.

2.3.2.2.9 Timing of Hunt (Seasonal Restrictions)

The Makah's waiver request includes timing restrictions that would prohibit hunting from June 1 to November 30 in any calendar year. According to the Tribe's waiver request, this measure is "designed to avoid any intentional harvest of gray whales" that have been identified within the PCFG survey area by hunting outside of times that coincide with the summer feeding period.

2.3.2.2.10 Proposed Hunting Method

The Makah Tribe plans to use both traditional and modern methods for hunting whales to balance the preservation of traditional cultural methods with safety and the need for increased hunting efficiency. Traditional and modern methods are relative terms because, as discussed in Subsection 3.9, Cultural Resources, the Tribe has adopted technological innovations over time. The Tribe considers traditional methods to be those that would be maintained based on their contribution to the ceremonial value of whaling. The Tribe's request includes the use of modern equipment when needed for safety, increased technological effectiveness, and/or to meet MMPA permit requirements.

The proposed method includes hunting whales from one or two sea-going canoes that are at least 30 feet (9 meters) long and carved by the Makah. Each canoe would be operated by an eight-person whaling crew (all Makah tribal members) and would include a harpooner and paddlers. One or more chase boats would accompany the canoes and either the canoe or chase boat would carry the whaling captain. Each chase boat would be operated by a pilot, diver, rifleman, backup harpooner, and at least one other crew member serving as a safety officer. Each chase boat would be equipped with a navigation system capable of fixing the vessel's position on the water. If neither chase boat had an engine capable of safely towing an adult gray whale to shore, there would be an additional vessel with that capability.

All action alternatives involve the same hunting method as proposed by the Tribe, except Alternative 3, which would involve only motorized vessels and not a canoe.

Method of Striking and Killing

The harpooner would use stainless steel harpoons with a toggle point. Each harpoon would be secured to a rope with float(s) attached. The harpooner would use one or more harpoons to make the first strike on the gray whale. If a harpoon strikes and affixes the toggle point and floats to the whale with the harpoon line attached, the rifleman in the chase boat would shoot it at close range with a high-powered, .50-caliber rifle with the intent of killing the whale with a shot to its central nervous system. A diver would attempt to sew the dead whale's mouth shut to prevent the whale from sinking. Although the Tribe proposed a specific method of striking and killing whales, public comments and our review of available information led us to consider additional methods in the some of the other action alternatives, as described below.

Optional Methods of Striking and Killing (Common among Action Alternatives)

Although the Tribe proposed a specific method of striking and killing whales, public comments and our review of available information led us to consider additional methods, including in the analysis of potential weapons impacts under Alternative 2. For all action alternatives, we consider the use of a darting gun that fires an explosive projectile into the whale. The hand-thrown darting gun consists of a barrel (to hold an explosive projectile) that is attached to a wooden shaft equipped with a toggle-point harpoon. The harpoon is intended to penetrate the whale and attach a line and float to secure the whale and assist in its recovery (O'Hara et al. 1999; Øen 2000; IWC 2007a). The barrel contains a trigger rod that ignites a propellant or "pusher" charge. This pusher charge fires the explosive projectile into the whale's body. The explosive projectile has a time delay fuse. The explosive projectile may be either black powder or penthrite and is intended to kill when it explodes inside the whale, either through shrapnel or blast injury. The cervical and

cranial thoracic regions are the critical targets for the darting gun projectile (O'Hara et al. 1999). If the initial darting gun projectile (primary strike) fails to kill the whale, the whale would be killed with additional explosive grenades delivered using either a smooth-bore, eight-gauge shoulder gun or a darting gun.

It would be reasonable to use the darting gun as an optional method of striking and killing whales regardless of the action alternative. For this reason, although other options for striking and killing are not part of the Tribe's proposal, this EIS examines this optional method as an element common among all action alternatives, including the Tribe's proposed action (Alternative 2). Impacts on individual whales from each of the optional hunting methods are described in further detail in Subsection 3.4.3.5, Welfare of Individual Whales.

Securing and Towing the Whale

Following a successful kill, the whaling crew would secure the whale with a line to tow it to a beach (mostly likely on the Makah Reservation), where tribal members could participate in celebrations and butchering, and tribal and/or NMFS biologists would measure and photograph the whale and take samples of tissues. Most of the whale products from the beached whale would be removed within 24 hours, including tissue samples collected by biologists.

The Tribe proposes to conduct research and development to refine whaling vessels, equipment, and hunting methods in consultation with NMFS to improve the safety, effectiveness, and humaneness of the gray whale hunt.

2.3.2.2.11 Whale Product Use and Distribution (Common Among Action Alternatives)

Limited Commercial Use and Distribution

The Makah Tribe would not sell or offer for sale whale products to the extent prohibited in WCA regulations. These regulations prohibit any person from selling or offering for sale whale products taken from an aboriginal subsistence hunt, except for authentic articles of native handicraft (which includes clothing) (50 CFR 230.4(f)). MMPA Section 102(f) prohibits take of whales incidental to commercial whaling. Although subsection 101(b) of the MMPA allows Alaska Natives to sell edible whale products in native villages and towns in Alaska or for native consumption, the Makah does not seek to sell or offer for sale any edible whale products. Any sales or offers to sell would be limited to non-edible whale products used to create authentic articles of native handicraft and could only be sold within the United States.

The Makah Tribe's whaling ordinance would prohibit tribal members who participate in any whale hunt from receiving monetary compensation, also in accordance with WCA regulations (50 CFR 230.4(e)).

Non-Commercial Use and Distribution

The Makah, within the borders of the United States, would be able to share edible whale products from any hunt under certain limited circumstances.

2.3.2.2.12 Other Environmental Protection Measures

Seabirds

Tatoosh Island and White Rock (which are located within the coastal portion of the Makah's U&A) support large seabird breeding colonies (Subsection 3.5.3.2.2, Non-Listed Birds and Their Associated Habitats). The Tribe proposes to avoid striking whales within 200 yards (183 meters) of Tatoosh Island and White Rock during May to minimize disturbance to feeding and nesting seabirds. The Tribe's additional proposal to prohibit hunting from June 1 through November 30 to protect PCFG whales would also help protect seabird breeding colonies. Measures to reduce impacts to seabirds on Tatoosh Island and White Rock are common among action alternatives. This same provision is incorporated into alternatives 4 (which prohibits hunting in this area in all months) through 6. Alternative 3 restricts hunting to the area beyond 5 miles (8 km) from shore, well beyond Tatoosh Island and White Rock. Alternative 7 allows for site restrictions to be included in hunt permits to protect sanctuary resources, which could include these areas in addition to any others identified in consultation with the OCNMS.

Public Safety Measures and Enforcement (Common Among Action Alternatives)

The Tribe proposes to implement public safety measures at least as restrictive as those described in its 2001 Gray Whale Management Plan . Those measures include the public safety measures the Makah Tribe previously employed in the 1999 and 2000 hunts, as well as additional measures that the Tribe plans to use for future whale hunts. The measures (described in more detail in Subsection 3.15, Public Safety, and in the Tribe's Whaling Ordinance, Appendix B) proposed by the Tribe include the following:

- The Makah Tribe whalers would use modern methods to kill a whale quickly; this would reduce the potential for a wounded whale to injure hunters or people in other vessels.
- All whalers would participate in whaler safety training, and drug and alcohol testing (see Training and Certification Process for Tribal Whalers, below).

- The whaling captain would also participate in captain training and certification. The captain would be responsible for the safety of his crew.
- Riflemen and/or whalers in charge of firing explosive charges would participate in training for proficient and accurate shooting under simulated hunt conditions.
- The rifleman or whaler in charge of firing explosive charges on board the chase boat would not be able to discharge his weapon until authorized to fire by a safety officer designated by the whaling captain. If a rifle were used, the safety officer would not authorize the discharge of the rifle unless the barrel of the rifle were above and within 30 feet (9 meters) of the target area of the whale, and the rifleman's field of view were clear of all persons, vessels, buildings, vehicles, highways, and other objects or structures that if hit by a rifle shot could injure humans or property.
- The whaling captain would suspend the hunt if visibility were less than 500 yards (457 meters) in any direction.
- The whaling canoe would have additional support boats available to provide first aid to whalers and help secure and tow the whale.
- All whaling equipment would be inspected before whaling.
- The Coast Guard would enforce the provisions of its permanent regulated navigation area (RNA) and moving exclusionary zone (MEZ), which would minimize the chance of bystanders accidentally being harmed during a hunt.

The Tribe further proposes to comply with additional safety measures that may be indicated as a result of this NEPA review.

Training and Certification Process for Tribal Whalers (Common Among Action Alternatives)

The Tribe proposes that if a hunt were authorized, it would require all tribal members who engage in whaling to be under the control of a whaling captain holding a valid whaling permit (also referred to as a license) issued by the Makah Tribal Council (see Subsection 1.2.4.2, National Whaling Governance under the WCA, for an explanation of responsibilities held by Native American whaling organizations). Whaling permits issued by the Council would incorporate and require compliance with all NMFS requirements, as well as tribal regulations. The regulations would also provide a training and certification process for all members who participate in whaling, as required by NMFS' WCA implementing regulations. Whaling team members may also partake in spiritual preparations.

The Makah Tribal Council would not issue a permit to a whaling captain unless it determined that the whaling captain and each whaling team member had been certified by the Makah Whaling Commission or Makah Fisheries Management Department to perform his assigned role on the whaling crew.

Makah Fisheries Management Department and NMFS Observers and Monitoring (Common Among Action Alternatives)

The Makah Tribe's waiver request includes accommodations for both a Makah Fisheries Management Department observer and a NMFS observer to accompany the whaling team in the chase boat(s). The Tribe would provide the designated NMFS observer with at least 24-hour notice of whaling permit issuance to the whaling captain by the Makah Tribal Council, unless the NMFS observer was already present on the Makah Reservation. The Tribe's request also indicates that the NMFS observer could collect samples from landed whales. This would include stomach contents, ovaries (as applicable), ear plugs, baleen plates, and other tissue samples. The Makah Fisheries Management Department would photograph all landed whales, and the Department's observer would be responsible for recording the time, date, location, and physical characteristics of each whale struck and, for each whale harvested, the body length, fluke width, sex, any fetus found in a landed whale, and the time to death for all whales harvested. The Tribe would have to report all monitoring data to NMFS annually.

Enforcement (Common Among Action Alternatives)

Tribal regulations would include provisions requiring tribal enforcement of the regulations and permit terms and conditions NMFS adopted, if hunting were authorized. These regulations would include criminal sanctions, such as fines and imprisonment, up to the limits imposed by the Indian Civil Rights Act. Violators may also be barred from exercising treaty fishing, hunting, and/or whaling rights for a minimum of 3 years.

Makah Department of Natural Resources Enforcement has been designated as the tribal law enforcement agency responsible for administering the requirements of whaling regulations and permits. A whaling captain would be liable for any violations committed by a member of the whaling team under his control.

In the event of violations of NMFS' regulations governing any authorized hunt, federal enforcement would also be possible. Potential offenses could include violation of the WCA and MMPA and any implementing regulations.

2.3.3 Alternative 3 (Offshore Hunt)

Alternative 3 would allow only two struck and lost whales (in contrast to Alternative 2, which would allow three stuck and lost) but would have the same conditions as Alternative 2 regarding numbers of ENP whales struck and harvested; seasonal restrictions; and regulatory conditions. Alternative 3 would also have the same hunt area as Alternative 2, except that it would require the use of a .577 caliber rifle and would prohibit Makah hunters from making an initial strike on a gray whale within 5 miles (8 km) of shore. (Makah hunters and chase boats may nevertheless have to follow any struck whale trailing harpoon lines to dispatch it, regardless of distance to shore.) To allow full consideration of different hunt methods, Alternative 3 also assumes an all-motorized hunt, with no use of a canoe.

Under Alternative 3, the Tribe would hunt from two or more motorized vessels, one operated by a pilot and the primary harpooner, and the other operated by a pilot, rifleman, harpooner, and at least one other crew member serving as a safety officer. One of the vessels would be at least 24 feet (7.3 meters) long and powered by an engine capable of safely towing an adult gray whale to shore. Each motorized vessel would be equipped with a navigation system capable of fixing the vessel's position on the water.

Alternative 3 would also differ from Alternative 2 in its approach to managing impacts to the PCFG. It would set an annual total mortality limit for PCFG whales equal to PBR, with an additional annual mortality limit for female PCFG whales equal to one-half PBR, using the PBR as applied to PCFG whales in NMFS' most recent stock assessment report (currently Carretta et al. 2023)[8]. Under present circumstances, this calculation would result in an annual mortality limit of approximately 3.5 PCFG whales total, with an additional limit of approximately 1.75 female PCFG whales. (Subsection 4.1.3, Alternative 3, describes in more detail how the limit would be calculated.) Also, Alternatives 3 differs from Alternative 2 in that the PCFG mortality limit would be based on cataloged whales seen in 2 or more years. This is consistent with the latest PCFG definition by the IWC Scientific Committee (which is based on sightings in 2 or more years).

The offshore hunt area under Alternative 3 is intended to address several issues raised in public comments on the 2008 DEIS and during the 2012 scoping process, including: the potential for bullets from a rifle to injure persons on shore; the potential for a hunt close to shore to affect aesthetic, cultural, and other social and economic resources; the potential for hunt activities to disturb wildlife on the rocks and islands of the Washington Islands National Wildlife Refuge; and the potential for an

[8] It is possible that future stock assessment reports could discontinue reporting values for PCFG whales. In that case, NMFS would base these calculations on an alternative source(s) for the best available scientific information regarding PCFG whales.

offshore hunt to be less likely to kill a PCFG whale (because PCFG whales may concentrate closer to shore and migrating whales may be farther offshore). The .577 caliber rifle would be expected to have a shorter range than the .50 caliber rifle (Subsection 3.4.3.5.4 Method of Killing and Time to Death, Rifle as the Killing Weapon), so it is reasonable to include that rifle as a component of Alternative 3 that is intended to mitigate risks on shore from gunshots.

Alternative 3 also responds to concerns that we should consider different mortality limits for males and females. A lower limit on female whales would limit impacts on reproduction within the PCFG and would also limit impacts on the recruitment of new PCFG members, because some PCFG whales are known to recruit to the group by accompanying their mothers to the area as calves (Subsection 3.4.3.4.1, PCFG Population Structure, PCFG Genetics and Recruitment).

2.3.4 Alternative 4 (Summer/Fall Hunt)

Alternative 4 would have the same conditions as Alternative 2 except the hunting season would be from June 1 through November 30, to avoid killing a WNP whale (because such whales would be feeding in the WNP at this time and not present in the Makah U&A). This alternative responds to concerns that a tribal hunt should be managed to avoid WNP whales. Because hunting would be allowed during the period that defines membership in the PCFG, Alternative 4 would also include restrictions specifically intended to manage impacts to the PCFG:

1. Hunters could only approach a whale identified as an ENP male by a trained onboard observer. Avoiding female whales in a tribal hunt would limit impacts on reproduction within the PCFG. It would also limit impacts on the recruitment of new PCFG members, because many PCFG whales are known to recruit to the group by accompanying their mothers to the area as calves (Subsection 3.4.3.4.1, PCFG Population Structure, PCFG Genetics and Recruitment).
2. An annual PCFG mortality limit would be set using the PBR formula in NMFS' most recent stock assessment report (currently Carretta et al. 2023), but using a recovery factor of 0.35, minus the estimated amount of mortality from other human causes, also as reported in NMFS' most recent stock assessment report.[9] Under present circumstances, this calculation would result in an annual mortality limit of approximately 0.76 PCFG whales (Subsection 4.1.4, Alternative 4, describes in more detail how the limit would be calculated). When the PCFG mortality limit is less than one but greater than 0.5 during 2 consecutive years, the values would be aggregated to allow for the mortality of one PCFG whale during the second

[9] *See* note 8, *supra*.

year. Therefore, under current conditions, one PCFG whale could be killed every two years. As described under Alternative 2, and in more detail in Subsection 3.4.2.1, Marine Mammal Protection Act Management, NMFS' stock assessment reports include an estimate of the level of human-caused mortality that will allow marine mammal stocks to achieve and remain above the lower level of their OSP. Other management goals are possible, however, such as achieving a population abundance that is closer to the stock's carrying capacity (Wade 1998). Applying the analysis in Wade (1998), a recovery factor of 0.35 would allow the PCFG to equilibrate at 80 percent of its carrying capacity over a 200-year period. By adopting this approach to setting a PCFG mortality limit, Alternative 4 responds to concerns that we consider an alternative management goal other than the PBR goal, which would allow exploitation of a stock at a level that just maintains it at the lower end of its OSP range. This alternative also responds to concerns raised by the Marine Mammal Commission that our NEPA analysis should consider accounting for other sources of human-caused mortality in setting a PCFG limit for a tribal hunt.

3. Unused portions of the PCFG mortality limit would not carry over to a subsequent year, except that when the allowable mortality level is less than 1 but greater than 0.5, it would be aggregated over 2 years, allowing for the mortality of one PCFG whale over 2 years. The purpose of not allowing mortality limits to carry over is to prevent mortality of multiple PCFG whales in a single year (unless the calculated mortality limit allowed for more than one whale to be killed)[10]. The purpose of allowing a carry-over when the mortality limit is greater than 0.5 but less than 1 is to afford the Tribe an opportunity to hunt at least every other year but with a harvest limit that is sensitive to declines in PCFG abundance or if PCFG whales are killed in unexpected numbers by other sources of human-caused mortality (the current level of human-caused mortality averages about 1.1 whales per year) (Carretta et al. 2023).
4. No hunting would be permitted when the PCFG mortality limit for a single year is less than 0.5. The purpose of this provision is to prohibit a hunt if the PCFG declines to half its current abundance or if PCFG whales are killed in unexpected numbers by other sources of human-caused mortality.
5. Any whale struck would be presumed to be a PCFG whale, even if it were landed and did not match a known PCFG whale. Although some portion of whales sighted in the west coast feeding areas during this period never return and are not considered PCFG whales, the majority of whales present during this period are PCFG whales. Also, it is likely that not all

[10] For example, the mortality limit could reach two whales in a single year if the PCFG minimum population estimate increased to 240 whales and all other variables remained constant (see Table 4-7).

PCFG whales have been identified; thus, there may be unidentified PCFG whales present in the Makah U&A during this period.

2.3.5 Alternative 5 (Split-season Hunt)

Alternative 5 would have the same conditions as Alternative 2, except (1) there would be two hunting seasons of 3 weeks each: one from December 1 through December 21 and one from May 10 through May 31; and (2) an annual PCFG mortality limit would be set at 10 percent of PBR as calculated for the PCFG in NMFS' most recent stock assessment report (currently Carretta et al. 2023).[11] Under present circumstances, this calculation would result in a PCFG mortality limit of approximately 0.35 whales per year, or one whale every 3 years (Subsection 4.1.5, Alternative 5, describes in more detail how the limit would be calculated). Any whale struck but not landed would be counted as a PCFG whale in proportion to the observed presence of PCFG whales in the Makah U&A during that season. Also, Alternative 5 differs Alternative 2 in that the PCFG mortality limit would be based on cataloged whales seen in 2 or more years. This is consistent with the latest PCFG definition by the IWC Scientific Committee (which is based on sightings in 2 or more years).

The choice of seasons is intended to avoid killing a WNP whale and to minimize the chance of killing a PCFG whale. There are no observations of WNP gray whales in the Makah Tribe's U&A, but we can infer the timing of their likely presence there from observations in other areas (including photo identification and satellite tag transmissions) and their migration habits and patterns.

The selection of the seasons under this alternative would be based on dates WNP whales are observed in other locations and their theoretical travel routes and travel times to or from those locations (Subsection 3.4.3.2.1, WNP Seasonal Distribution, Migration and Movements). Unlike Alternative 4, Alternative 5 also avoids the season that defines the PCFG. This alternative responds to concerns that a tribal hunt should be managed to avoid WNP whales while still minimizing the chance of taking a PCFG whale.

Setting a limit at 10 percent of PBR is consistent with NMFS' implementation of other sections of the MMPA governing marine mammal mortality. For example, Section 118 sets a goal for the incidental mortality of marine mammals in commercial fisheries at "insignificant levels approaching a zero mortality and serious injury rate." We have interpreted this goal as being met when commercial fisheries result in a mortality rate of marine mammals that is 10 percent or less

[11] *See* note 8, *supra*.

of PBR (69 FR 43338, July 20, 2004). Section 101(a)(5)(A) of the MMPA allows us to authorize the lethal take of "small numbers" of marine mammals if the take is not intentional, is incidental to a specified activity, and will have a "negligible impact" on the marine mammal stock. The same requirements apply to incidental but not intentional lethal take in commercial fisheries of marine mammals listed as threatened or endangered under the ESA (Section 101(a)(5)(E)). We interpret negligible impact to mean:

> An impact resulting from the specified activity that cannot be reasonably expected to, and is not reasonably likely to, adversely affect the species or stock through effects on annual rates of recruitment or survival (50 CFR 216.103).

In practice, we consider an incidental take that does not exceed 10 percent of PBR to have a negligible impact (64 FR 28800, May 27, 1999).

2.3.6 Alternative 6 (Different Limits on Strikes and PCFG, and Limited Duration of Regulations and Permits)

Alternative 6 would have the same conditions as Alternative 2, except that strikes would be limited to seven over 2 years; an annual PCFG mortality limit would be set using the PBR formula as applied to the PCFG in NMFS' most recent stock assessment report (Carretta et al. 2023), minus other sources of human-caused mortality (similar to Alternative 4)[12]; and all whales struck but not landed would count against the PCFG limit based on their proportional presence during the season they were struck and lost (similar to Alternative 5). The PCFG mortality limit would also be based on cataloged whales seen in 2 or more years. This is consistent with the latest PCFG definition by the IWC Scientific Committee (which is based on sightings in 2 or more years).

In addition, the waiver of the MMPA take moratorium would expire 10 years after adoption, and regulations governing the hunt would limit the term of any hunt permit to not more than 3 years.

By reducing the total number of strikes allowed compared to Alternative 2, Alternative 6 could reduce by as much as half the likelihood of a WNP whale being killed or harassed. Also, the limited duration of the MMPA waiver for take of ENP gray whales under Alternative 6 would serve two purposes. First, as described in Subsection 3.4.3.4.1, PCFG Population Structure, the status of the PCFG as a separate population stock under the MMPA remains unresolved. By adopting regulations with a set termination date, we would assure that the most up-to-date information regarding the status of the PCFG as a population stock would be considered after not

[12] *See* note 8, *supra*.

more than 10 years. We selected 10 years because it allows a reasonable amount of time for NMFS to develop additional information about stock structure.

Finally, Alternative 6 would, by regulation, limit the term of any permit issued to the Makah Tribe to 3 years. The MMPA allows permits to be issued for up to 5 years and the Makah Tribe's request anticipates 5-year permits. Limiting the permit term to 3 years provides an opportunity for more frequent NMFS review than if permits were issued for 5 years. Some commenters on the 2008 DEIS recommended we include a permit period less than 5 years for this reason.

2.3.7 Alternative 7 (Composite Alternative— Preferred)

Alternative 7 combines various elements from Alternative 2 through 6. While the proposed hunt method, target species, age and reproductive status restrictions, and other environmental protection measures (Subsection 2.3.2.2.12) outlined in Alternative 2 are the same under Alternative 7, many other aspects of the Preferred Alternative differ from the Tribe's initial request based on subsequent consideration, public comment, the hearing record, and the recommendation of the ALJ.

Under this alternative, the waiver of the MMPA take moratorium would be valid for 10 years and subject to numerous provisions contained in NMFS' proposed regulations to govern a Makah Tribe gray whale hunt (84 FR 13604, April 5, 2019). Limiting the waiver period provides an opportunity for adaptive management and to ensure that ceremonial and subsistence hunting by the Tribe does not result in unanticipated adverse effects. An initial hunt permit may last no more than 3 years, with subsequent permits lasting no more than 5 years. Two management goals shaped many of the provisions in the proposed regulations and Alternative 7: (1) limiting the likelihood that tribal hunters would strike or otherwise harm a WNP gray whale and (2) ensuring that the hunting does not reduce PCFG abundance below recent stable levels.

2.3.7.1.1 Number of Whales Struck and Harvested (Annual and 10-Year)

Alternative 7 imposes strike limits and landing limits for each hunt season. No more than 25 ENP gray whales may be killed over the 10-year waiver period, and no more than 20 may be harvested (i.e. killed and landed). During winter/spring hunts, a maximum of three whales may be struck regardless of whether or not they are landed. During summer/fall hunts, a maximum of two whales may be struck but only if the first whale is lost (i.e., struck but not landed). "Strike" or "struck" is defined in NMFS' proposed regulations as to cause a harpoon, darting gun, or other device, or a projectile from a rifle or other weapon, to penetrate a gray whale's skin or an instance in which a gray whale's skin is penetrated by such a weapon or projectile during hunting. Once a

whale has been struck, any subsequent strikes on that same whale will not count against the limit. In other words, multiple strikes on the same whale count as a single struck whale.

WNP whales are not expected to be encountered during a summer/fall hunt because current evidence indicates they would have returned to summer feeding grounds in the WNP (Weller et al. 2012; Mate et al. 2015). In contrast, during a winter/spring hunt there is a very small risk of striking a WNP whale that has migrated to the ENP wintering grounds (Moore et al. 2023). Therefore, under Alternative 7, in order to receive a permit for a winter/spring hunt, the Tribe must also obtain an Incidental Take Authorization (ITA) under the MMPA for WNP whales. Furthermore, under Alternative 7, the Tribe could only strike one whale in a 24-hour period during a winter/spring hunt as a precaution against striking multiple WNP gray whales that might be traveling together in a group (Weller et al. 2012). In the unlikely event the Tribe struck a WNP whale, all hunting would cease unless and until NMFS determined that measures were taken to ensure that no additional WNP gray whales would be struck during the remainder of the waiver period.

2.3.7.1.2 Limits on Harvesting PCFG Whales

In contrast to the PBR-based approach used in Alternatives 2 through 6 to limit PCFG mortality, Alternative 7 relies on static strike limits and low-abundance thresholds to manage impacts on PCFG whales. Specifically, no more than 16 PCFG whales may be struck over the 10-year waiver period, and no more than eight of these whales can be females. To determine if a landed whale belonged to the PCFG, observers would photograph the whale and provide those photographs to NMFS and the Cascadia Research Collective to compare with the PCFG photo catalog. The PCFG mortality limit during winter/spring hunt years would be based on cataloged whales seen in 2 or more years. This is consistent with the latest PCFG definition by the IWC Scientific Committee (which is based on sightings in 2 or more years). During summer/fall hunts, all struck whales—whether struck and landed or struck and lost—will count as a member of the PCFG, unless identified as a WNP gray whale.[13] During winter/spring hunts, struck whales that cannot be identified will be counted in proportion to the estimated percentage of PCFG whales in the hunt area during the month of the strike, based on the best available scientific information. Also, hunting would be prohibited if the current or the forecasted abundance of the PCFG fell below 192 whales, or if its minimum abundance fell below 171 whales. Hunting could resume once the

[13] Although WNP whales are not expected to be present in the Makah U&A during this season, we would check for matches via the available WNP catalogs.

most recent or forecasted abundance, and minimum abundance, increased above their respective thresholds.

2.3.7.1.3 Whale Approached and Subjected to Unsuccessful Strike Attempts

Recognizing that actions by tribal hunters, short of killing a gray whale, may affect whales and may constitute a take under the MMPA, the Preferred Alternative would limit the number of approaches and unsuccessful strike attempts, including those associated with hunt training. Under Alternative 7, the Tribe would be required to obtain an ITA for WNP gray whales in order to make training approaches from November 1 through June 30 due to the likelihood that a WNP whale may be encountered during these months over the 10-year waiver period (Weller et al. 2012; Mate et al. 2015; Moore et al. 2023). Alternative 7 would authorize no more than 353 ENP gray whales to be approached (including both hunting and training approaches) each calendar year, of which no more than 142 could be PCFG whales. Any hunting approach on a gray whale that has already been struck would not count against these limits. As with strikes (Subsection 2.1.3 above), approaches in winter/spring hunts would take into account the proportion of PCFG whales expected to be encountered, while in summer/fall hunts, all whales approached would count as PCFG whales. Training approaches during June through November in any year would count as PCFG whales. Consistent with permit conditions imposed by NMFS for research vessels pursuing large cetaceans, an "approach" is defined as causing a hunting or training vessel to be within 100 yards of a gray whale.

Alternative 7 would also limit the number of whales subjected to unsuccessful strike attempts to 18 during winter/spring hunt years, and 12 during summer/fall hunt years. Each training harpoon throw will count against the unsuccessful strike attempt limit in effect during the calendar year that the throw is made. Training harpoon throws could occur in any month in winter/spring hunt years. In contrast, training harpoon throws would be restricted to the hunting season in summer/fall hunt years (July through October, when WNP whales are not expected in the hunt area) to reduce the risk of encountering WNP whales over the waiver period. Similar to the limit on approaches, the purpose of these provisions is to limit the risk of nonlethal impacts, particularly to WNP and PCFG whales.

2.3.7.1.4 Location of Hunt (Area Restrictions)

Consistent with Alternative 2, the hunt area would be limited to the portion of the Makah Tribe's U&A west of the Bonilla-Tatoosh Line and would also incorporate additional site restrictions via the hunt permitting process to protect OCNMS resources. Alternative 7 combines the timing of the hunt seasons of Alternatives 2 and 4 by incorporating an alternating hunt season scheme

wherein winter/spring hunts would occur during the migration season (December 1 through May 31) to reduce the risk to PCFG whales, and summer/fall hunts would occur during the feeding season (July 1 through November 30) to reduce risk to the WNP stock. Only one hunt season would be authorized each year; however, the winter/spring hunts may start in the same calendar year as a summer/fall hunt. This results in a 1-month gap (November) between the end of a summer/fall hunt and the start of a winter/spring hunt, and a 13-month gap between the end of a winter/spring hunt and the start of the next summer/fall hunt, and so on.

2.3.7.1.5 ENP Low Abundance Threshold

Although NMFS' proposed regulations did not include an ENP population low abundance threshold, the ALJ recommended, in light of the current UME, that the hunt regulations include an abundance threshold for the ENP gray whale stock below which the hunt would not be permitted. NMFS received three suggestions for thresholds in the 45-day public comment period following the publication of the Recommended Decision. If NMFS includes a low abundance threshold for the ENP stock in the final rule and the abundance estimate for the ENP stock were to drop below the selected threshold, hunting could resume once the abundance estimate increased above the threshold again.

In this EIS, the impacts of the hunt under Alternative 7 are analyzed both without a low abundance threshold (Preferred) and with the addition of each of the three thresholds proposed in the public comment period, which are analyzed as sub-alternatives:

7(a) 11,000 whales

7(b) 16,000 whales

7(c) 18,000 whales.

The rationale for the three proposed thresholds are as follows. Threshold 7(a) (11,000 whales) represents the lowest estimate in the time series of ENP gray whale abundance estimates produced by NMFS beginning in 1967. Since this low was observed in 1971, the population grew to a high of approximately 27,000 animals in 2016 (Durban et al. 2017). This growth occurred despite the concurrent subsistence harvest of ENP gray whales by Chukotka Natives in Russia and at least one major UME in 1999-2000. Threshold 7(b) (16,000 whales) represents an approximation of the lower bound of OSP based on the estimate of carrying capacity calculated by Punt and Wade (2012). Finally, threshold 7(c) (18,000 whales) represents the lower bound of OSP if carrying capacity were to be calculated using the upper 95% confidence interval of the most recent, pre-UME abundance estimate (approximately 30,000 animals).

2.3.7.1.6 Whale Product Use and Distribution

Under Alternative 7, provisions are made for the use and distribution of both edible and nonedible products. Enrolled members of the Makah Indian Tribe would be permitted to possess, consume, and transport edible whale products such as meat and blubber within and outside the Tribe's reservation borders. They would also be permitted to share and barter these products with other tribal members. Tribal members would be permitted to share these products with non-members within the reservation boundaries or at the tribal member's residence, should they reside outside the reservation. Tribal members could also share edible products with non-members at tribal or intertribal gatherings sanctioned by the Makah Tribal Council in quantities under two pounds per person attending the gathering.

Members of the Makah Tribe would also be permitted to possess, transport, share, and barter nonedible whale products, such as bone and baleen, with other tribal members both within and outside the reservation borders. Handicrafts made from these nonedible products could also be shared, offered for sale, and bartered with both members and non-members, with a permanent, distinct marking approved by the Makah Tribal Council and a certificate of authenticity if such products are to be taken outside the reservation boundaries.

2.4 Alternatives Considered but Eliminated from Detailed Analysis

During the scoping process for this EIS, we reviewed several alternatives but eliminated them from further detailed analysis. These alternatives and the reasons for their elimination from detailed analysis are explained below.

2.4.1 Non-lethal Hunt

A non-lethal hunt alternative was requested by some members of the public during the scoping process as well as on the 2015 DEIS. The commenters did not fully describe the details of this alternative, but it would likely include the Tribe engaging in some ceremonies and training preparatory to a hunt, a pursuit of whales on the water, and a mock attack on a whale, but would not culminate in a whale being killed or transported to shore.

The Federal treaties and statutes that NMFS is responsible for implementing are important in informing and identifying reasonable alternatives. Under the WCA and implementing regulations, whaling (which is synonymous with hunting in the aboriginal subsistence use context) clearly contemplates killing and attempts to kill whales (16 USC 916(j) and 50 CFR 230.2). Likewise, the definition of take under IWC and the MMPA contemplates lethal takes (16 U.S.C. 1362(13); 50 CFR 216.3). The right of fishing and of whaling or sealing was secured by the Makah through

the 1855 Treaty of Neah Bay, which was written when fishing and whaling or sealing conveyed the opportunity to take animals lethally from each of these categories. The Tribe's waiver request seeks authorization to kill whales under those existing legal authorities and its interpretation of the scope of its treaty. A non-lethal hunt would therefore not meet the purpose and need for the proposed action.

In addition, the non-lethal hunt alternative would have similar effects on the human environment as the No-action Alternative; therefore, its detailed analysis would not provide additional information to inform agency decision-making or the public's consideration. The conservation impacts on gray whales and the local ecosystem would be the same as the No-action Alternative because no gray whales would be removed by the Tribe from the population or from the ecosystem. The impact to the Makah Tribe would be the same as the No-action Alternative because the Tribe would not be allowed to hunt whales according to their historical and contemporary cultural understanding or within their understanding of the scope of their treaty right (in this respect, a non-lethal ceremonial hunt would also not meet the Makah Tribe's purpose and need). The other social and economic impacts would be the same as the No-action Alternative because a non-lethal hunt would not have significantly different public safety, aesthetic, sentimental, or economic impacts than if no hunting occurred. In addition, with a non-lethal hunt, gray whales would still be subjected to approaches and being struck with non-lethal weapons. To the extent such disturbance might cause whales to change their distribution, that effect is analyzed under the proposed action.

2.4.2 Subsistence Use of Drift Whales

Several commenters suggested that the Makah use drift whales (also known as stinker whales), rather than live whales, for subsistence purposes. Drift whales are whales that die naturally or as a result of some human activity other than a directed hunt (for example, entanglement in fishing gear). The large body size of the gray whale and its thick layer of blubber trap heat inside the whale after it dies, leading to rapid internal decomposition that makes most stranded whales unsuitable for human consumption.[14] This alternative would be essentially the same as the No-action Alternative.

[14] Since 1978, a total of 12 entangled gray whales have been reported within the Makah U&A (NMFS 1995; Scordino and Mate 2011; NMFS 2013a; Carretta et al. 2014; Carretta et al. 2020). Of these, there is only record of the Makah Tribe making use of one such whale (in 1995). Effective with passage of the 1994 Amendments to the MMPA, members of the Northwest treaty Indian tribes advised NMFS of their intent to exercise their treaty rights to marine mammals (i.e., as was done with the 1995 whale carcass used by Makah tribal members) (NMFS 1995). However, the Tribe's usual response is to assist an entangled animal, and tribal biologists have participated in several recent disentanglement efforts, including help with two humpback whales in 2008 and 2010 (Cascadia Research Collective 2008, 2010a) and the successful

The conservation impacts on gray whales and the local ecosystem would be the same as those under the No-action Alternative because no gray whales would be removed from the population or from the ecosystem as a result of a hunt. The social and cultural impacts on the Makah would be the same as those under the No-action Alternative because they would not be allowed to hunt whales according to their historical and contemporary cultural understanding and within their concept of the scope of their treaty right. In this respect, a decision allowing only subsistence use of drift whales is inconsistent with NMFS's federal trust responsibilities to the Makah Tribe with respect to the Tribe's reserved whaling rights under the Treaty of Neah Bay and would not meet the Tribe's purpose to resume its traditional hunting of gray whales under its treaty right. While this alternative would differ from the No-action Alternative because it would provide the Makah with an occasional and unpredictable supply of whale products, the agency could provide for the Tribe's use of drift whales without invoking the MMPA waiver provision (NOAA and Makah Indian Tribe 1989). The other social and economic impacts would be the same as those under the No-action Alternative, because the subsistence use of drift whales would not have significantly different public safety, sentimental, or economic impacts than a no-hunt alternative. The use of drift whales might have an impact on aesthetics, but some of that impact (the sight of a dead whale being butchered on the beach) would be the same as in any of the action alternatives. In addition, for the reasons described under the non-lethal hunt alternative (Subsection 2.4.1, Non-lethal Hunt), this alternative would not meet the purpose of and need for the proposed action.

2.4.3 Set a Mortality Limit for PCFG Whales Relying on other MMPA Provisions or Management Goals

Several commenters on the 2008 DEIS and 2015 DEIS stated that PBR was not appropriate for setting limits on harvest of PCFG whales, as proposed by the Tribe. We therefore considered other examples for setting mortality limits for marine mammals. One is incorporated into Alternative 4 (set a mortality level that would allow the PCFG to maintain 80 percent of carrying capacity), another into Alternative 5 (set a mortality limit at 10 percent of PBR), and a third into Alternative 7 (set static mortality limits and low abundance thresholds based on recent stable

disentanglement of gray whales in 2009 and 2013 (NMFS 2013a). Similarly, NMFS stranding records show that of the animals that have stranded and died in the Makah U&A since 1994, only one had body parts (blubber and muscle, quantity unknown) that were used by the Tribe (Renker 2012), and all whales were in a moderate to advanced state of decomposition at the time the carcass was examined (K. Wilkinson, NMFS, pers. comm., February 18, 2014). In 2018, a dead humpback whale found in the Strait of Juan de Fuca was utilized by the Tribe after being examined by the tribal marine mammal biologist and a biologist with the Cascadia Research Collective, both of whom confirmed ship strike as the cause of death (Mapes 2018).

population levels). We also examined other provisions of the MMPA that allow us to authorize killing marine mammals.

Waiver of the take moratorium under Section 101(a)(3) of the MMPA is the only means of authorizing intentional killing of marine mammals except for subsection 109 (which allows us to return authority over marine mammals to the states, who may then authorize killing) and Section 120 (which allows us to authorize states to kill seals and sea lions that are harming at-risk salmonid stocks). In addition, Section 101(b) exempts Alaska Natives from the take moratorium but allows us to regulate such hunting for a depleted stock.[15] Other provisions of the MMPA allow us to authorize lethal and non-lethal take of marine mammals incidental to other activities. As described in Subsection 1.1.3, Summary of Gray Whale Status, we do not presently recognize the PCFG to be a separate marine mammal stock, but have found that it "may warrant consideration as a distinct stock in the future" and have established an informational PBR for it (Carretta et al. 2023). During internal scoping, we therefore considered whether any of these other provisions of the MMPA provide alternative methods of setting a mortality limit on PCFG whales that should be analyzed.

2.4.3.1 Section 109 Return of Authority to States

In adopting the MMPA, Congress expressly superseded state authority to manage marine mammals, but provided a mechanism in Section 109(b) for returning that authority. Once a state has authority to manage marine mammals, it may authorize their killing if (1) the state has determined that the marine mammal stock is at OSP; (2) the state has determined the number of animals that may be taken without causing it to go below its OSP; and (3) the state does not permit the taking of a number greater than such number, including takes for subsistence purposes by Alaska residents (sections 109(b)(1)(C)(i)). We decided not to analyze in detail an alternative that would have a management scheme for PCFG whales similar to that of subsection 109(b) because Alternatives 3 through 7 already employ such a management scheme (that is, set a harvest level that will not cause the PCFG to fall below the lower bound of OSP). Including this alternative would therefore not provide additional information for the decision-maker.

2.4.3.2 Section 120 Authorization to Kill Seals and Sea Lions

In 2004, the states of Oregon, Washington, and Idaho requested authorization to kill California sea lions at Bonneville Dam on the Columbia River under Section 120 of the MMPA. That provision allows us to authorize states to kill seals and sea lions that are having a significant

[15] Section 101(f) authorizes intentional killing in self-defense or defense of others and does not involve an authorization from NMFS.

negative impact on the decline or recovery of at-risk salmonids. The states proposed to limit the number of sea lions that could be removed each year to 1 percent of PBR and we adopted that limit in the authorization. In our EA, we concluded that killing a number of California sea lions up to 1 percent of PBR per year would not have a significant effect on the California sea lion population as a whole (NMFS 2008b).

We decided not to analyze in detail an alternative that would set a mortality limit for PCFG whales of 1 percent of PBR because such an alternative would not be substantially different from the No-action Alternative and so would provide no additional information for the decision-maker. Under current conditions, a mortality rate for PCFG whales of 1 percent of PBR would allow for the mortality of 0.035 PCFG whales per year or one whale every 29 years. In the event the Tribe killed a PCFG whale in a hunt, there would be no hunt for almost 3 decades, which we consider equivalent to the No-action Alternative. In addition, a tribal hunt would be so infrequent under this alternative that it would not meet the purpose of and need for the proposed action.

2.4.3.3 Regulation of Alaska Native Hunting of Depleted Beluga Whales

In 2008 we adopted regulations under MMPA Section 101(b) governing Alaska Native hunting of Cook Inlet beluga whales after we had designated the stock as depleted (73 FR 60976, October 15, 2008). The regulations do not allow harvest when the 5-year average population abundance is less than 350 whales and set a harvest limit at abundance levels above that based on the principle of a 95 percent certainty that the harvest would not delay the stock's time to recovery by more than 25 percent. We decided not to analyze in detail an alternative that would set a mortality rate limit for PCFG whales following the beluga whale model because there is no evidence that the PCFG is declining, as is the case for belugas. We therefore considered the model as not applicable. Subsection 3.4.3.4.3, PCFG Abundance and Trends, describes in detail the current status of the PCFG, which increased prior to 2002 and has since been relatively stable (Harris et al. 2022). In addition, according to the analysis in Wade (1998), using a recovery factor of 0.35 in the PBR equation would not delay the time to recovery by more than 25 percent for a cetacean population with characteristics similar to the PCFG. Alternative 4 already incorporates a harvest limit based on a recovery factor of 0.35; therefore, including this alternative would not provide additional information to the decision-maker.

2.4.4 Hunt Other Marine Mammal Species Traditionally Hunted by the Tribe

This alternative, which was suggested by some members of the public, would substitute a gray whale hunt with a hunt for a different whale species or another marine mammal. Because the United States has not requested on behalf of the Makah that the IWC set ASW catch limits for

another large cetacean, and because the IWC has not considered such a request, the WCA precludes NMFS from publishing a quota for other whale species for the use of the Makah Tribe. In addition, some whales, such as the humpback whale and some marine mammal species (such as the western stock of Steller sea lions), are listed under the ESA.

Also, if non-ESA listed marine mammal species, such as pinnipeds or small cetaceans (e.g., dolphins and porpoises), were entirely or partially substituted for a gray whale, the total biomass harvested and the method used would likely differ (i.e., more individuals caught using different catch methods). As explained in Subsection 3.9, Cultural Resources, whaling and sealing do not hold equivalent historical or contemporary ceremonial and subsistence harvest values for the Makah Tribe. These differences would include the type of food obtained (blubber, meat, and whale bone), associated spiritual ceremonies, hunting activities (methods, timing, and area), and subsistence uses. In this respect, requiring substitution of other marine mammal species in lieu of gray whales is inconsistent with NMFS's federal trust responsibilities to the Makah Tribe with respect to the Tribe's reserved whaling rights under the Treaty of Neah Bay and would not meet the Tribe's purpose to resume its traditional hunting of gray whales under its treaty right. A hunt focused on non-ESA listed pinnipeds and small cetaceans would be a different type of action, is too speculative to allow for a NEPA analysis, and would not meet the purpose of and need for the proposed action.

2.4.5 Change the Hunt Location

We considered other alternatives for either increasing or decreasing the Makah gray whale hunting area. Hunt location options that were considered but eliminated from further study are described in the following sections.

2.4.5.1 Hunt Outside the OCNMS but within the Offshore Migratory Path in the U&A

This option would allow the Makah to hunt whales in a small portion of the Tribe's U&A seaward of the outer Olympic Coast National Marine Sanctuary (OCNMS) boundary (Figure 1-1). The area off the coast of Washington that is outside the Strait of Juan de Fuca and the OCNMS but is within the Makah U&A is too small to provide for a successful hunt, is outside the Coast Guard RNA, and is beyond the 27-mile (43-km) offshore area where most whales have been sighted migrating past Washington (see Subsection 3.4.3.3.1, ENP Seasonal Distribution, Migration and Movements, for more information). For these reasons, this alternative would not meet the purpose of and need for the proposed action.

Although the purpose of this proposed alternative would be to safeguard the natural resource values that led to designation of the OCNMS as a national marine sanctuary, OCNMS regulations

allow for a Makah tribal hunt if otherwise legally permitted (15 CFR 922.152(a)(6)). OCNMS regulations allow for taking marine mammals pursuant to any treaty with an Indian tribe, as long as the taking is consistent with the MMPA, ESA, and Migratory Bird Treaty Act (16 USC 1431 *et seq*.). Alternative 3 (Offshore Hunt) allows for consideration of Sanctuary resources in greater detail, therefore consideration of this proposed alternative would not provide additional information or meet the purpose and need of the proposed action.

2.4.5.2 Hunt in Russia with Chukotka Natives

Members of the Makah Tribe currently have the option of hunting with the Chukotka Natives. Only those Makah Tribe members who participate in the hunt in Russia would have the opportunity to share in the ceremonial and subsistence value of the hunt because, by international law (Convention on the International Trade of Endangered Species), no whale products may be transferred out of the country of origin. Under the MMPA, in addition to international law, importing a marine mammal product without receiving authorization under the waiver process would be illegal.

This option would not allow the Makah Tribe to conduct a ceremonial hunt in its U&A using traditional Makah practices, nor would most of the tribal members be able to participate in celebrations that occurred when a whale was landed in Russia. Further, this option would not meet the Tribe's stated purpose and need to exercise its cultural values or treaty right. This option would require no action on the part of NMFS; therefore, it is similar to the No-action Alternative. Analysis of this alternative would not provide the agency or the public with information useful in informing our decision, because this alternative would require no decision on NMFS' part.

2.4.6 Employ Different Hunting Methods

During the scoping process, NMFS identified the following methods of striking and killing whales, based on the Tribe's request, internal NMFS scoping, public comments, and an examination of aboriginal subsistence hunting world-wide: (1) a toggle point harpoon to strike the whale and a .50 caliber rifle to kill the whale (as proposed by the Tribe); (2) a toggle point harpoon to strike the whale and a .577 caliber rifle to kill the whale; (3) a darting gun with explosive projectile as the striking and/or killing weapon; (4) a shoulder gun with explosive projectile as the killing weapon; (5) traditional methods only (harpoons to strike whales and lances to kill whales); and (6) a smaller caliber rifle as the killing weapon. The following subsections explain our rationale for not analyzing options 5 and 6 in detail. The other options are analyzed in detail as an element of the various action alternatives.

In reviewing public comment on the 2008 DEIS, we identified another alternative hunting method not considered in the scoping process or draft EIS. That alternative is the use of an all-motorized hunt. We included this element under Alternative 3 to allow consideration of whether use of an all-motorized hunt might expand hunting potential to other times of year and areas farther offshore, might improve the welfare of individual whales by decreasing time to death or the proportion of whales struck and lost, and/or might improve hunter or public safety.

2.4.6.1 Hunt Using Only Traditional Methods

This potential alternative, suggested in public comment on the 2008 DEIS and the 2015 DEIS, is best characterized as requiring the Makah to hunt using only pre-contact hunting methods. This would mean, for example, using mussel-tipped harpoons instead of toggle-point or steel-tipped harpoons, prohibiting the use of rifles to kill whales, and prohibiting the use of chase boats with outboard motors to follow the hunt and to tow whales. More information about pre-contact Makah hunting techniques can be found in Subsection 3.10.3.4, Makah Historic Whaling.

This alternative was eliminated from detailed consideration for a variety of reasons. The information presented in this FEIS related to the method of the hunt must support and inform NMFS' decisions about waiving the MMPA moratorium or issuing a permit. The agency may only issue a permit to take a marine mammal upon a determination that the manner of taking is humane (16 USC 1374(b)(2)(B)), which the MMPA defines as "the least possible degree of pain and suffering practicable" (16 USC 1362(4)). A whale may take several hours or days to die using only pre-contact methods. Modern technologies, such as those analyzed in detail in this EIS, result in quicker times to death than a hunt using only pre-contact methods, meaning pre-contact methods would not meet the MMPA's humaneness standard.

WCA regulations also require that hunting not be conducted in a wasteful manner, which "means a method of whaling that is not likely to result in the landing of a struck whale or that does not include all reasonable efforts to retrieve the whale" (50 CFR 230.2). The use of powered vessels and backup hunters (e.g., harpooners and the rifleman) to chase and tow whales represents reasonable efforts to retrieve any struck whale and is more likely to meet WCA regulatory requirements than hunting using only traditional vessels.

Safety of hunters and the public must also be considered. A wounded whale experiencing a lengthy death could pose a greater risk to the whaling crew and public. This situation can be avoided by using some modern tools.

This alternative also does not meet the proposed action's purpose and need. Also, requiring the Makah to hunt with pre-contact weapons, boats, and other tools is not justified because technologies, including using steel-tipped harpoons and accepting tows from steam-powered commercial tow boats, were used in traditional hunts as they became available.

2.4.6.2 Kill Whales with Smaller Caliber Rifles

Many of the aboriginal subsistence whale hunts conducted world-wide on large whales employ rifles to kill whales; some of these rifles are smaller than the .50 caliber rifle under the Proposed Action and the .577 caliber rifle used in the Makah's 1999 hunt. Three separate reports (Ingling 1999; Beattie 2001; Graves et al. 2004) have now examined humane killing and public safety aspects of the proposed Makah whale hunts, and all three authors concluded that a.50 caliber rifle (or greater) is the appropriate caliber of weapon to use.

Specifically, Ingling (1999) concluded that for large game, larger bullets are more effective in producing penetration deep enough to reach a vital organ or disabling site in the animal and thus require more power (i.e., heavier guns). In addition, rifles that are at least .50 caliber provide a better margin of error in targeting compared to smaller caliber rifles. Graves et al. (2004) added that "small caliber rifles simply will not do the job" of quickly killing large thick-boned whales; they concluded that the .50 caliber weapon was the best choice. Russian government reports on the number of small-caliber rifle rounds fired per whale in the Chukotka Native gray whale hunt support this conclusion (Subsection 3.4.3.5.4, Method of Killing and Time to Death). It is also supported by the recommendations from a recent IWC workshop report that identified several chemical and physical techniques for euthanasia of stranded whales, including high-caliber ballistics and explosives for baleen and sperm whales (IWC 2014a). The Ingling and Graves reports are discussed in further detail in later sections of this FEIS (Subsection 3.15, Public Safety). As described in Subsection 2.4.6.1, Hunt Using Only Traditional Methods, the MMPA prescribes that taking a marine mammal must involve "the least possible degree of pain and suffering practicable" (16 USC 1362(4)). Smaller caliber rifles would not result in the least possible degree of pain and suffering practicable.

2.4.7 Alternative Compensation to the Makah Tribe

Compensation to the Makah Tribe for not whaling could be monetary, including financial support for a different venture (such as ecotourism associated with whale watching). Other types of compensation might be a loan for a casino resort, new facilities for health care improvements, other options for improving the quality of life on the reservation, or renegotiating the treaty and returning ceded lands. Any of these actions would, however, result in environmental conditions

similar to those described under the No-action Alternative. No whale hunting would occur, and the other financial incentives (such as loans for casinos, resorts, improved health care, or ecotourism opportunities) would be provided to the Tribe with its agreement to forego future whaling. The No-action Alternative could occur at any time and would not be restricted to a specific future event. The Tribe was offered financial compensation by a private party in lieu of whaling during the fall of 1998. The Tribe, at that time, would not consider this offer (Anderson 2008a; Anderson 2008b; Tizon et al. 2008), and the tribe has maintained that position. This alternative was eliminated from further consideration because any of these activities would be speculative, with uncertain negotiations between the Tribe and other government and nongovernmental entities. In addition, this alternative would not meet NMFS's federal trust responsibilities to the Makah Tribe with respect to the Tribe's reserved whaling rights under the Treaty of Neah Bay or the Tribe's purpose to resume its traditional hunting of gray whales under its treaty right. Finally, impacts would be similar to the No-action Alternative; thus, a detailed examination of this alternative would not develop relevant information for the decision-maker.

2.4.8 Alternatives Not Carried Forward from the 2008 DEIS

The 2008 DEIS contained alternatives not carried forward here. One alternative would have required the Tribe to hunt outside 200 yards (183 meters) of any rocks or islands, to protect nesting seabirds and hauled-out marine mammals. We did not include that alternative here because Alternative 3, Offshore Hunt, would authorize hunting only outside 5 miles (8 km) from shore, which is beyond any rocks or islands.

The 2008 DEIS also contained alternatives that would have authorized the Tribe to hunt in the Strait of Juan de Fuca and to hunt year-round. We do not include those alternatives here. Alternative 4, Summer/Fall Hunt, analyzes the impacts of hunting during the summer season, rendering a year-round option unnecessary. The Tribe did not request and no commenters recommended a Makah gray whale hunt in the Strait of Juan de Fuca.

One alternative included in the 2008 DEIS would have set lower limits than those proposed by the Tribe on the total numbers of whales struck, struck and lost, and harvested. Analysis completed for the 2012 IWC Scientific Committee meeting shows that establishing a set annual limit of one or two PCFG whales did not meet the IWC's conservation objectives (IWC 2012d). Since that time, the Scientific Committee has convened five range-wide workshops on the status of North Pacific gray whales (IWC 2019a) and has analyzed a new proposed management plan that is now presented as Alternative 7. After modeling the available data (i.e., biology, ecology, abundance and trends, removals including direct hunting, ship strikes, and bycatches), the

Scientific Committee concluded that this proposed hunt management plan meets the IWC conservation objectives for ENP gray whales, as well as for PCFG and WNP gray whales (IWC 2023a, Punt et al. 2023; see Subsection 1.2.4.1, International Whaling Governance under the International Convention for the Regulation of Whaling).

LIST OF FIGURES

3.0 AFFECTED ENVIRONMENT

This section describes the affected environment (environmental conditions in the action area) to provide background information for the assessment of the environmental effects of the alternatives discussed in Section 4 (Environmental Consequences) and Section 5 (Cumulative Impacts). The affected environment subsections describe the pertinent aspects of resources and the current conditions within the action area that will be used to evaluate the anticipated environmental effects of the alternatives described in Section 2 (Alternatives). The first subsection describes geographically based management in the action area (including federally and internationally designated areas, and tribal management of reservations and usual and accustomed (U&A) fishing grounds) to provide context for the description of the other sections. The remaining subsections present the physical environment first, followed by the biological environment, then the social environment, of the action area.

The resources considered for environmental review in Sections 3 through 5 of this FEIS are those that we have identified as having the potential to be affected by the action alternatives. To determine which resources to analyze, we first compiled a complete list of physical, biological, and social resources during internal agency project scoping. We then reduced the list to those that might have any potential to be affected by the action alternatives and published notices of intent in the Federal Register requesting public comments on various components of the EIS, including resources to be analyzed. After considering public comments, some resources were identified as not having the potential to be affected by the action alternatives, and are, therefore, not analyzed in this FEIS. These resources include utilities, air quality, geology and soils, hazardous waste, energy, housing, light and glare, and National Historic Preservation Act cultural properties.

3.1 Geographically Based Management in the Action Area

The action area is confined primarily to the marine waters, islands, and land areas near the Makah Tribe's U&A in the Pacific Ocean and Strait of Juan de Fuca that may be directly or indirectly affected by the proposed whale hunt (Figure 1-1) (Subsection 1.1.2, Makah Tribe's Proposed Hunt Location). The action area encompasses several federally designated and managed areas, including the Olympic Coast National Marine Sanctuary (OCNMS or Sanctuary), the Washington Islands National Wildlife Refuges, the United States Coast Guard (Coast Guard) regulated navigation area (RNA), Olympic National Park, and internationally designated areas, including a United Nations World Heritage Site and the Olympic Biosphere Reserve. The action area also includes the Makah and Ozette Reservations. These designated and managed areas have

objectives and policies that are directly or indirectly related to the action alternatives, as described below.

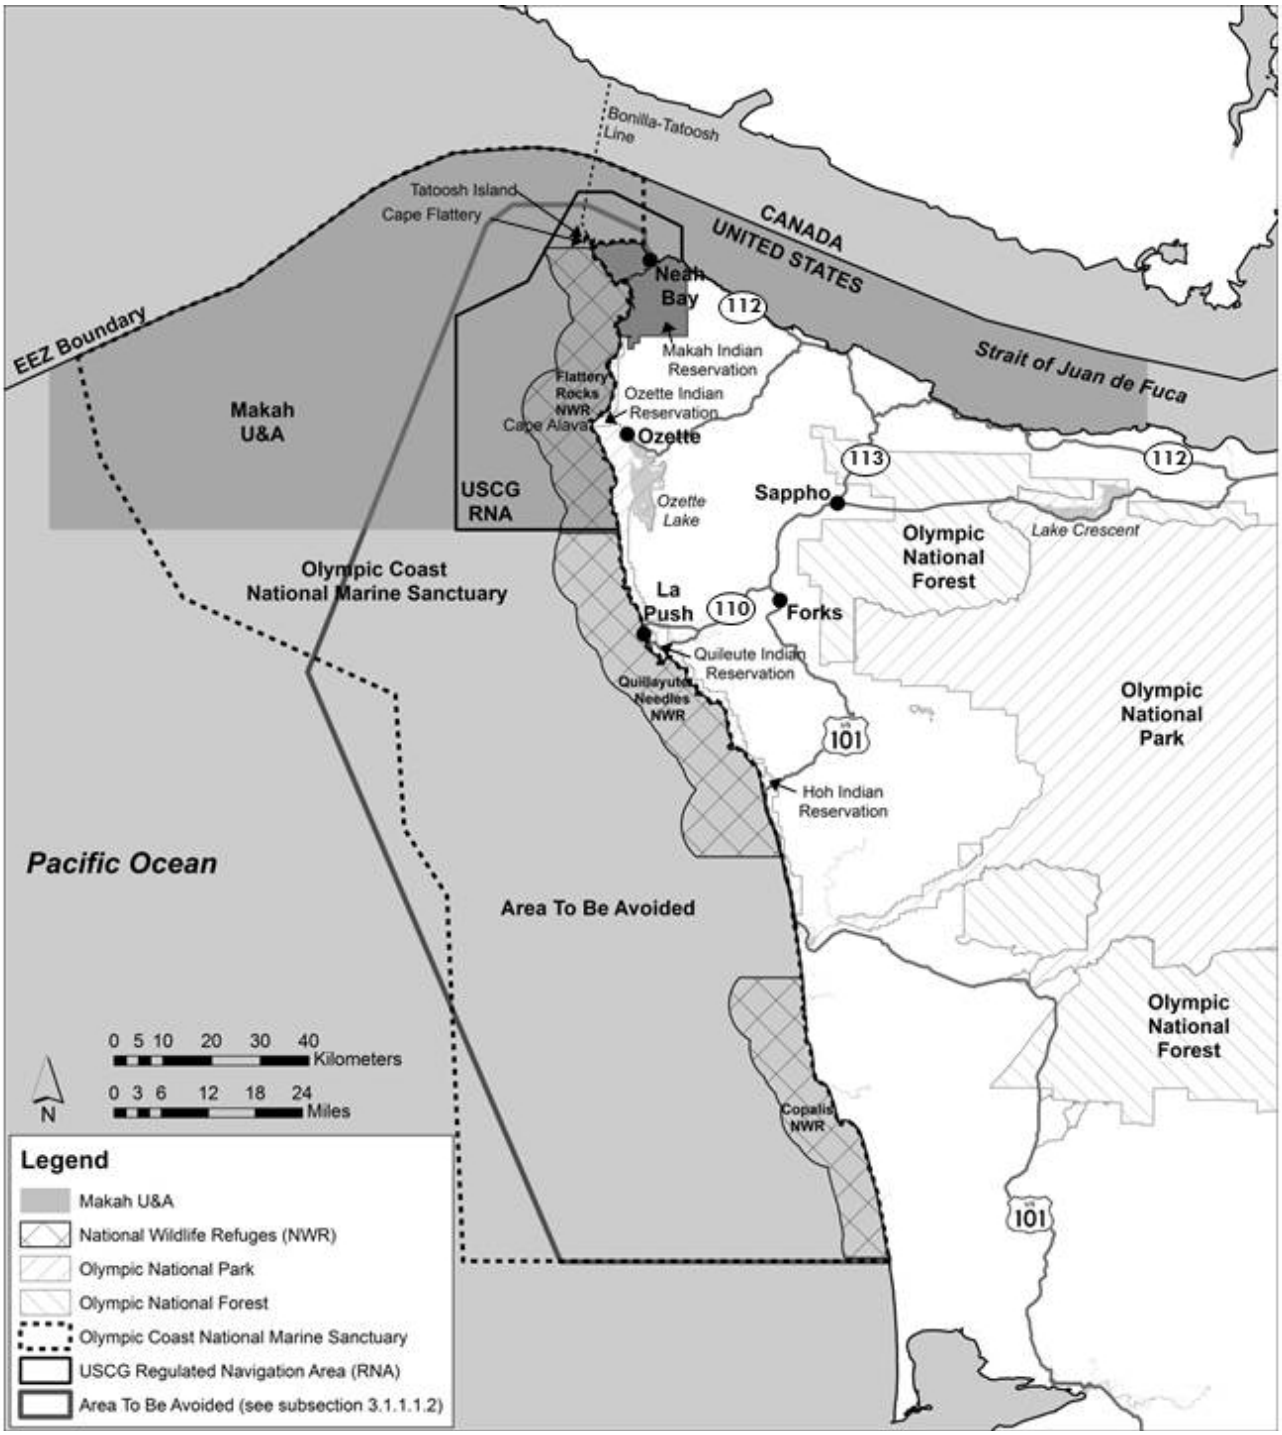

Figure 3-1. Designated and Managed Areas.

3.1.1 Designated Areas

3.1.1.1 Olympic Coast National Marine Sanctuary

3.1.1.1.1 Introduction

Olympic Coast National Marine Sanctuary (OCNMS or sanctuary) is one of 15 national marine sanctuaries in United States waters, located off the northwest coast of Washington state and encompassing a 3,188-square mile area of coastal and ocean waters and submerged lands along the Olympic Peninsula and the western portion of the Strait of Juan de Fuca. Figure 3-1, Designated and Managed Areas, identifies the portion of OCNMS located in the action area.

3.1.1.1.2 Designation and Regulatory Overview

The Secretary of Commerce designated OCNMS in 1994 as an area of special national significance under the authority of the National Marine Sanctuaries Act (16 USC 1431 *et seq.*) because of its unique and nationally significant collection of flora and fauna, and adjacency to Olympic National Park. In the OCNMS Designation Document (published in 59 FR 24586, May 11, 1994) and 1993 Final EIS and Management Plan (NOAA 1993), NOAA noted that the sanctuary is a highly productive, nearly pristine ocean and coastal environment that is important to the continued survival of several ecologically and commercially important species of fish, seabirds, and marine mammals. In the OCNMS Designation Document and the Final EIS and Management Plan, NOAA enumerated biological and historical resources that give the sanctuary particular value (NOAA 1993), including high biological productivity, diversity of habitats, a wide variety of marine mammals and birds living in or migrating through the area, and the presence of endangered and threatened species and essential habitats.

In particular, NOAA noted that the unusually large and diverse range of habitats present in the sanctuary includes the following:

- Offshore islands and rocks (most are within the Flattery Rocks, Quillayute Needles, and Copalis national wildlife refuges);
- Large and diverse kelp beds;
- Intertidal pools;
- Erosional features (such as rocky headlands, seastacks, and arches),
- Interspersed exposed beaches and protected bays;
- Submarine canyons and ridges;
- The continental shelf (including a broad shallow plateau extending from the mouth of the Juan de Fuca canyon);
- Continental slope environments.

The numerous sea stacks and rocky outcrops along the sanctuary shoreline, coupled with a large tidal range and wave splash zone, support some of the most diverse and complex intertidal zones in the United States (59 FR 24586, May 11, 1994). NOAA also identified several historical resources that give the sanctuary particular value, including Indian village sites, ancient canoe runs (intertidal pathways cleared of boulders and cobble), petroglyphs, Indian artifacts, and numerous shipwrecks (NOAA 1993; 59 FR 24586, 24604, May 11, 1994). Extensive archeological work oriented toward late prehistoric culture had been completed by the Makah Tribe and archaeologists along the Washington coastline at the time of designation, including a major archeological dig conducted at Ozette, near Cape Alava that uncovered an ancient village thought to be 2,000 years old and considered to be one of the most significant excavations in North America (NOAA 1993). NOAA also found that an important feature of the sanctuary is its proximity to four Native American tribes, Hoh Tribe, Makah Tribe, Quileute Tribe, and Quinault Indian Nation, and the sanctuary is within their U&As. Tribal members use their U&As for subsistence and commercial harvesting, religious ceremonies, exercise of treaty-reserved rights, research, and numerous other uses. The presence of Indian tribes along the coast adds unique governance dynamics as well as special cultural and historical significance to the sanctuary (NOAA 1993).

NOAA's National Ocean Service, Office of National Marine Sanctuaries, administers OCNMS, which is managed by sanctuary staff in Port Angeles, Washington. The mission statement of OCNMS is to "protect the Olympic Coast's natural and cultural resources through responsible stewardship, to conduct and apply research to preserve the area's ecological integrity and maritime heritage, and to promote understanding through public outreach and education." These multiple-use management objectives are achieved through both cooperative management and regulation. NOAA finds that one of the major benefits of establishing OCNMS is the integration of important nearshore and oceanic marine resource zones and corresponding human activities, including federal, state, and tribal management of those activities, under one coordinated management regime (NOAA 1993). To this end, sanctuary staff coordinates management with the Washington State Departments of Ecology (Ecology), Natural Resources, Fish and Wildlife, and Agriculture; the United States and Canadian coast guards; the United States Fish and Wildlife Service (USFWS); the National Park Service; the four Coastal Treaty Tribes (Hoh Tribe, Makah Tribe, Quileute Tribe, and Quinault Indian Nation); local businesses, towns, counties, and timber and fishing representatives; and research and education institutions. The Olympic Coast National Marine Sanctuary Advisory Council was established in 1999 to provide advice on the management and protection of the sanctuary. A community-based body, the Advisory Council,

through its members, serves as a liaison to the community regarding sanctuary issues and represents community interests, concerns, and management needs to the sanctuary. The council comprises representatives of tribal governments, state and local governments, other federal agencies, maritime industry, fishing, education, tourism, conservation organizations, and the community at large. The Sanctuary Advisory Council operates under a charter and serves strictly in a voluntary, advice-giving role. OCNMS staff also reviews ocean management in the sanctuary with the four Coastal Treaty Tribes, including the Hoh Tribe, Makah Tribe, Quileute Tribe, and Quinault Indian Nation, and the state of Washington, through the Intergovernmental Policy Council (NOAA 2007). The Intergovernmental Policy Council was created by a memorandum of agreement signed in 2006 and updated in 2012, 2017, and most recently amended in 2022 (NOAA 2007; NOAA 2012; NOAA 2018).

Regulations governing OCNMS are located at 15 CFR Part 922, Subpart O. The regulations describe sanctuary boundaries, prohibit certain kinds of activities, and set up a permitting system to allow some activities that are otherwise prohibited. Activities generally prohibited in OCNMS include offshore oil, gas, and mineral exploration, development, or production; pollution discharge; seabed disturbance; and possessing, moving, removing, or injuring any historical resource. Prohibited activities that are particularly relevant to the action alternatives include flight level restrictions and marine mammal take restrictions. Flying motorized aircraft at less than 2,000 feet both above the sanctuary and within one nautical mile of the shoreline or National Wildlife Refuge islands is prohibited under 15 CFR 922.152(7), unless the sanctuary staff issues a permit (with certain exceptions such as valid law enforcement, emergency response, and specified tribal activities). This prohibition is consistent with the 2,000-foot flight advisory over the adjacent Olympic National Park and national wildlife refuges and is designed to limit the potential effects of noise, particularly as it might affect hauled-out seals and sea lions, sea otters, and nesting birds along the shoreline and offshore rocks and islands of the sanctuary (NOAA 1993; 77 FR 3919, January 26, 2012).

Regulations also prohibit taking any marine mammal, sea turtle, or seabird in or above the sanctuary, except as authorized by the MMPA, the ESA, and the Migratory Bird Treaty Act, or pursuant to any treaty with an Indian tribe to which the United States is a party (15 CFR 922.152(6)). If the taking is conducted pursuant to an Indian treaty, the taking is to be exercised in accordance with the MMPA, ESA, and the Migratory Bird Treaty Act, to the extent that they apply (15 CFR 922.152(6)). For applicability of these federal laws to the Makah Tribe's treaty

right of taking fish and of whaling or sealing at usual and accustomed grounds and stations, refer to Section 1, Purpose and Need, and Section 2, Alternatives, of this FEIS.

3.1.1.1.3 Current Issues

Management Plan. The 2011 OCNMS Management Plan contains goals and objectives for collaborative partnerships, resource management, research, and education programs (NOAA 2011). The management plan contains 20 action plans, organized under five goals: (1) achieve effective collaborative and coordinated management; (2) conduct collaborative research, assessments, and monitoring to inform ecosystem-based management; (3) improve ocean literacy; (4) conserve natural resources in the sanctuary; and (5) understand the sanctuary's cultural, historical, and socioeconomic significance. The Makah Tribe is a key partner in many of the activities within the 20 action plans. NOAA initated a review of the management plan in January 2023 to evaluate progress toward implementing the goals of the sanctuary and revise the plan as necessary to fulfill the purposes and policies of the NMSA (88 FR 6236, January 1, 2023). The review is expected to take one to two years before any revisions are implemented.

Area to be Avoided (ATBA). In 1995, sanctuary staff worked with the Coast Guard and the International Maritime Organization to establish an area to be avoided for the primary purpose of preventing a catastrophic oil spill. The Area to be Avoided (ATBA) is a voluntary ship traffic management program that applies to all ships and barges carrying cargoes of oil or hazardous materials, as well as all ships of a certain size that are solely in transit. Effective December 1, 2012, the applicable vessel size for ATBA compliance was lowered from 1,600 to 400 gross tons. Operators of such vessels are advised to maintain a 25-mile buffer from the coastline in the southern portion of the area to be avoided, narrowing to approximately eight nautical miles west of Cape Flattery and one nautical mile (1.15 miles) north of Neah Bay. This area to be avoided corresponds largely with the nearshore portion of the Makah Tribe's U&A (Figure 3-1). The restrictions do not apply to vessels that are engaged in an otherwise permitted activity that occurs predominantly within the sanctuary, such as fishing or research. Of 6,554 vessel transits through the sanctuary in 2021, all but 678 remained outside of the ATBA, equating to an estimated compliance rate of 89.7 percent (OCNMS 2022). Since 2017, average voluntary compliance with the ATBA has been 94 percent. More information on vessel traffic can be found in Subsection 3.13.3.2, Marine Vessel Traffic. See also Subsection 3.2.3.3, Spill Prevention.

Sanctuary Cooperation with the Makah Tribe. The Makah Tribe is a key partner in OCNMS coordinated management, research, resource protection, public relations, education, and outreach. OCNMS has a trust responsibility and government-to-government relationship with the Hoh

Tribe, Makah Tribe, Quileute Tribe, and Quinault Indian Nation. As such, OCNMS consults with the Coastal Treaty Tribes on sanctuary policies or decisions that could affect them. The sanctuary also works with the Makah Tribe on a variety of other programs and projects. The Makah Cultural and Research Center has fostered a strong relationship with the sanctuary through development and implementation of a cooperative interpretive program centered on the Makah Reservation. Since 2000, the sanctuary has provided annual funding to the Makah Cultural and Research Center to hire Makah interpreters and guides at Cape Flattery. Each year, Makah interpreters engage with thousands of visitors who learn about Makah culture, collaborative management of the sanctuary, and natural history within the area. In 2022, more than 24,000 visitors visited Cape Flattery during the 17-week summer program. Sanctuary staff also supported the creation of the Makah Office of Marine Affairs to provide technical assistance in developing and planning pollution prevention strategies and to represent the Tribe's interest in guarding treaty-protected resources from oil spills (NOAA 2006). For more information on spill prevention, see Subsection 3.2.3.3, Spill Prevention. Since 2007, the Makah Tribe has also been a member of the Sanctuary's Intergovernmental Policy Council and holds a seat on the Sanctuary Advisory Council.

3.1.1.2 Washington Islands National Wildlife Refuges

More than 870 islands, rocks, and reefs above the mean high water line and extending for more than 100 miles (161 km) along the coast of Washington State are included in three national wildlife refuges: Quillayute Needles, Flattery Rocks, and Copalis (collectively called the Washington Islands National Wildlife Refuges). The islands range from less than 1 acre (0.4 ha) to about 36 acres (15 ha), and most drop abruptly into the sea. The islands' offshore location provides protection from human disturbance and land predators while providing close proximity to abundant ocean food sources. The islands provide refuge for more than 20 species of birds as they nest and raise their young; the total population of seabirds, waterfowl, and shorebirds may exceed 1 million birds (Subsection 3.5.3.2, Existing Conditions, Other Marine Wildlife). In addition, sea lions, seals, sea otters, porpoises, and whales are commonly found on and/or around the islands (Subsection 3.5.3.1, Existing Conditions, Marine Mammals). All three refuges were originally established as migratory bird sanctuaries through Executive Orders 703, 704, and 705 issued by President Theodore Roosevelt in 1907, and later redesignated as refuges in 1940 (Presidential Proclamation, July 30, 1940) and wilderness areas in 1970 (under the Wilderness Act of 1964, 16 USC 1131 *et seq.*), except for Destruction Island, which was excluded because of the presence of an operational Coast Guard lighthouse on the island. Only the Flattery Rocks National Wildlife Refuge is within the Makah Tribe's U&A and the OCNMS; it extends along

the Pacific Coast from the western edge of Cape Flattery south to near the southern boundary of the Makah U&A.

The refuges are maintained as a sanctuary for nesting seabirds and marine mammals and are managed by the USFWS. The USFWS coordinates with NOAA's Olympic Coast National Marine Sanctuary staff to prohibit motorized aircraft flying less than 2,000 feet above certain portions of the refuges. The USFWS also manages the refuges cooperatively with the National Park Service through a memorandum of understanding because the refuges are within the exterior boundaries of Olympic National Park (National Park Service and USFWS 1993). The objective of the Washington Islands National Wildlife Refuges is to enhance protection and interpretation of the wildlife, and natural and scenic resources of the refuges by taking the following measures:

- Minimizing human impacts
- Maintaining the wilderness character of the area
- Helping the public understand and appreciate the value of the refuges
- Conducting research to understand the refuge resources

The USFWS has also issued advisories and permits regulating public access to the islands and closed public access to the islands and surrounding waters within 200 yards (183m) to avoid the flushing of nesting seabirds by boat and other vessel traffic (USFWS 2023). All of the islands in the action area are less than 3 miles from shore.

The USFWS prepared a Washington Islands National Wildlife Refuges Comprehensive Conservation Plan/Environmental Assessment (EA) (USFWS 2007) to guide its management of the Flattery Rocks National Wildlife Refuges, as well as the Quillayute Needles and Copalis National Wildlife Refuges. Management activities include monitoring the refuge wildlife and protecting and maintaining the natural functioning ecosystem. The plan directs the USFWS to coordinate with other agencies and tribes to ensure continuation of the long-term health and viability of native seabird and marine wildlife populations, with a focus on pinnipeds. The Washington Islands National Wildlife Refuges Comprehensive Conservation Plan/EA includes the Treaty of Neah Bay as a law or executive order potentially applicable to its Comprehensive Conservation Plan/EA (USFWS 2007) (specifically, the Tribe's fishing, whaling, and sealing rights within its U&A, as well as hunting and gathering rights on open and unclaimed lands). The Washington Islands National Wildlife Refuge System adheres to laws, regulations, and policies applicable to all National Refuge Systems (50 CFR Subchapter C, Parts 25 to 32). Goals, objectives, and strategies applicable to the Washington Islands National Wildlife Refuge Comprehensive Conservation Plan/EA are listed below:

- Protect migratory birds and other native wildlife and their associated habitats, with special emphasis on seabirds.
- Protect and support the recovery of federally threatened and endangered species and Washington State special status species and their associated habitats.
- Promote and manage the Washington Islands Wilderness Area to maintain its wilderness character and values.
- Promote effective coordination and cooperation with others for conservation of refuge resources, with special emphasis on government agencies and tribes with adjoining ownership and/or jurisdiction.
- Continue to enhance long-term monitoring and sustained applied research.
- Increase public interpretation and awareness programs to enhance appreciation, understanding, and enjoyment of refuge resources.

3.1.1.3 Coast Guard Regulated Navigation Area

The United States Coast Guard has established an RNA (Figure 3-1) in the Strait of Juan de Fuca and adjacent coastal waters of northwest Washington (33 CFR 165.1310) under its Ports and Waterways Safety Act authority (33 USC 1221 *et seq.*), allowing the Coast Guard to regulate vessel activities near any Makah whale hunt and reduce the danger of loss of life and property from any hunt. When finalizing the RNA after the 1999 hunt, the Coast Guard specifically found that "the uncertain reactions of a pursued or wounded whale and the inherent dangers in firing a hunting rifle from a pitching and rolling small boat are likely to be present in all future hunts, and present a significant danger to life and property if persons or vessels are not excluded from the immediate vicinity of a hunt" (64 FR 61212, November 10, 1999).

The RNA rests entirely within the Makah U&A (Figure 3-1). The RNA boundaries enclose waters off Neah Bay and the Strait of Juan de Fuca in the north, wrap around Cape Flattery and Tatoosh Island, and then parallel the shore at a 10-nautical-mile (11.5-mile/18.5-km) distance until the southern boundary is formed by connecting to the shore at the southern extent of the U&A. The Coast Guard extended the southern boundary of the RNA to match the southern boundary of the U&A when the final rule was promulgated in 1999 (64 FR 61212, November 10, 1999). When the interim rule (63 FR 52609, October. 1, 1998) was in force during the 1999 Makah whale hunt, most of the Makah whale hunting and associated protesting activities occurred farther south than the borders of the RNA (though the whale hunting activities and the protesting incidents still occurred within the Makah U&A) (Subsection 1.4.2, Summary of Recent Makah Whaling – 1998 through 2013).

Within the RNA during any Makah whale hunt, a Moving Exclusionary Zone (MEZ) for "the column of water from the surface to the seabed within a radius of 500 yards (457 m) centered on the Makah whale hunt vessel" is activated when one Makah whale hunt vessel displays an international numeral pennant five (5) between sunrise and sunset when surface visibility exceeds 1 nautical mile (33 CFR 165.1310(b)). No person or vessel may enter the MEZ when it is activated, except for the authorized Makah whale hunt vessel and an media pool vessel preauthorized by the Coast Guard. An additional vessel(s) or person(s) can be authorized by the Coast Guard (33 CFR 165.1310(c)), such as an observer vessel. An authorized media pool vessel must maneuver to avoid positioning itself between whales and hunt vessels, out of the line of fire, at a prudent distance and location relative to the whale hunt operations, and in a manner that avoids hindering the hunt or path of the whale in any way (33 CFR 165.1310(f)(3)). The media pool vessel operates at its own risk, but must adhere to safety and law enforcement instructions from Coast Guard personnel (33 CFR 1310(f)). The regulation does not affect normal transit or navigation in the RNA. For more information about the operation of the RNA and the MEZ during Makah whale hunting from 1998 to 2000, refer to Subsection 1.4.2, Summary of Recent Makah Whaling – 1998 through 2007; Subsection 3.15.2.1, Vessel Safety Regulations and Authorities; and Subsection 3.15.3.4, Behavior of People Associated with the Hunt.

3.1.1.4 Olympic National Park

The Olympic National Park comprises 922,651 acres located primarily in the center of the Olympic Peninsula and includes lands along the upper northern coast of Washington State (Figure 3-1). President Theodore Roosevelt originally created the Olympic National Monument in 1909; Congress later redesignated and authorized the monument as a National Park in 1938 (Chapter 812, 52 Stat. 1241). In 1988, Congress designated about 95 percent of the park (876,669 acres) as wilderness through the Washington Park Wilderness Act (16 USC 90 note, PL 100-668). It is now one of the largest wilderness areas in the contiguous United States. Combined with the OCNMS, the two designations protect almost 5,000 square miles (12,950 sq. km) of intertidal, island, and ocean habitats. The National Park Service is the federal agency that manages the park to preserve and protect, unimpaired, the park's diverse natural and cultural resources and provide for the enjoyment, education, and inspiration of present and future generations. More than 650 archeological sites documenting 10,000 years of human occupation are protected within the Olympic National Park lands (National Park Service 2008). Ten Olympic Peninsula tribes retain their ongoing connection to traditional lands within the park, including the Makah Tribe, Hoh Tribe, Jamestown S'Klallam Tribe, Quileute Tribe, Quinault Nation, Skokomish Tribe, Squaxin Tribe, Suquamish Tribe, Elwha Klallam Tribe, and Port Gamble

S'Klallam Tribe. The park also protects cultural resources that reveal and document the 200-year history of discovery, exploration, homesteading, and community development in the region (National Park Service 2008).

The National Park Service prepared a general management plan/EIS for the park that describes a vision for its future (National Park Service 2008). The plan is intended to guide park decision-making for 15 to 20 years. Management emphasis for the National Park Service's preferred alternative is protecting resources and improving visitor experiences. This goal would be accomplished by accommodating diverse visitor use, providing sustainable access on existing roads, improving mass transit opportunities, and concentrating improved educational and recreational opportunities on the developed park edges.

3.1.1.5 World Heritage Site

The Olympic National Park was designated as a United Nations Educational, Scientific, and Cultural Organization World Heritage Site in 1981, and it is one of 20 World Heritage Sites in the United States (UNESCO 1981). The World Heritage Site list was established under the terms of the Convention Concerning the Protection of World Culture and Natural Heritage that was adopted in 1972 at the 17th General Conference of the United Nations Educational, Scientific, and Cultural Organization. World Heritage Site objectives are to encourage the identification, protection, and preservation of cultural and natural heritage sites that are considered to be of outstanding value to humanity. These sites are listed in order to protect them for future generations to appreciate and enjoy.

3.1.1.6 Olympic Biosphere Reserve

The Olympic Peninsula, including the Olympic National Park, was designated as a biosphere reserve in 1976 (UNESCO 1976). Biosphere reserves are areas of terrestrial and coastal ecosystems promoting solutions to reconcile the conservation of biodiversity with sustainable use. The reserves are internationally recognized, nominated by national governments, and remain under sovereign jurisdiction of the states where they are located. Each biosphere reserve is intended to fulfill three basic functions:

- Conservation function that contributes to the conservation of landscapes, ecosystems, species, and genetic variation;
- Development function that fosters economical and human development that is socio-culturally and ecologically sustainable;

- Logistic function that provides support for research, monitoring, education, and information exchange related to local, national, and global issues of conservation and environment.

The objective of this designation is to set aside areas with representative ecosystems to achieve the fullest possible biogeographical cover over the world and ensure systematic conservation of biodiversity.

The Olympic Biosphere Reserve is one of 28 designated biosphere reserves in the United States. This reserve is considered one of the best examples of intact and protected temperate rainforests in the Pacific Northwest. Other outstanding characteristics include rivers supporting some of the best habitat for anadromous fish species, the longest undeveloped wilderness coast in the United States, and rich native and endemic animal and plant species (UNESCO 1981).

3.1.1.7 Other Designated Areas

NMFS and the Pacific Fishery Management Council (PFMC) have identified essential fish habitat within the action area under Magnuson-Stevens Act authority. More information about the establishment and identification of essential fish habitat and habitat areas of particular concern is presented in Section 3.3, Marine Habitat and Species. We have also identified ESA critical habitat for certain threatened and endangered species occurring within the action area. More information on critical habitat of fish species occurring within the action area is in Section 3.3, Marine Habitat and Species. More information on critical habitat for other marine wildlife, including for Southern Resident killer whales (71 FR 69057, Nov. 29, 2006), is in Subsection 3.5.3.1.1, ESA-Listed Marine Mammal Species, and Subsection 3.5.3.2.1, ESA-Listed Species (Other Marine Wildlife).

3.1.2 Makah Management of Reservation and U&A Areas

The Makah Reservation is located on the northwestern-most tip of the Olympic Peninsula (Figure 3-1) and encompasses 44 square miles (114 sq. km) of land (30,142 acres) bounded by the Pacific Ocean to the west and the Strait of Juan de Fuca to the north. The approximately 1-square-mile (2.6 sq. km) Ozette Reservation, 10 miles (16 km) south of Neah Bay, is also part of the Makah Reservation, with the Olympic National Park managing the contiguous shoreline between the two areas of the reservation.

The relationship between the United States and the Makah Tribe was formalized upon ratification of the Treaty of Neah Bay in 1855. Following the 1975 Indian Self-Determination and Education Assistance Act (PL 93-638), the Tribe entered into self-determination contracts with the Bureau

of Indian Affairs (BIA). Later, the Tribe entered into tribal self-governance compacts in accordance with the Tribal Self-Governance Act of 1994 (PL 103-413). The tribal self-governance compact incorporates virtually all BIA programs on the reservation. The Tribe has also entered into a self-governance compact with the Department of Health and Human Services (under the Tribal Self-Governance Amendments of 2000, PL 106-260), addressing the delivery of health services to tribal members. In addition, following a series of court decisions establishing the right of the Makah and other Washington state treaty tribes to half the harvestable surplus of salmon (*United States v. Washington* 1974) and shellfish (*United States v. Washington* 1994 (Rafeedie decision)), the federal government formally recognized that the four Washington coastal tribes (Makah, Quileute, Quinault, and Hoh) have treaty rights to groundfish in their respective U&As (PFMC and NMFS 2006). In accord with these decisions and recognition, the Makah Tribe participates in a variety of fisheries management forums such as the North of Falcon process, the Pacific Fisheries Management Council, the Pacific Salmon Treaty, the International Pacific Halibut Commission, and Pacific Whiting Treaty Joint Management Committee.

The Makah Tribe is governed by an elected tribal council. The Constitution and Bylaws of the Makah Indian Tribe, adopted in 1936, describe the organization and authority of the Makah Tribal Council. The council consists of five members elected for staggered 3-year terms. The Makah Tribal Council selects officers from its membership, including, but not limited to chairman, vice-chairman, and treasurer. Currently, the secretary is appointed from outside the Makah Tribal Council. The secretary is a tribal employee fulfilling the requirements of the office on behalf of the Makah Tribal Council. Any enrolled tribal member who is 21 years of age or older and has lived on the reservation for 1 year immediately preceding an election is eligible to vote, and any legal voter is eligible to be elected to serve on the Council.

As stated in the Constitution and Bylaws of the Makah Indian Tribe, the powers of the Tribal Council include the power to perform the following actions:

> To promulgate and enforce ordinances, which shall be subject to review by the Secretary of the Interior, governing the conduct of members of the Makah Indian Tribe, and providing for the maintenance of law and order, and the administration of justice by establishing a reservation Indian court and defining its duties, powers, and limitations . . . . To safeguard and promote the peace, safety, morals and general welfare of the Makah Indian Tribe by regulating the conduct of trade and the use and disposition of property upon the reservation . . . . To adopt resolutions regulating the procedure of the council itself and other tribal agencies and tribal officials of the reservation (Article IV, Sections 1(i), (j), and (n)).

The constitution and bylaws may be amended by a majority vote of the qualified tribal voters. A referendum on any proposed or enacted ordinance or resolution of the Tribal Council may be called if at least one-third of the qualified tribal voters petition for one. The majority vote of such a referendum is conclusive and binding on the Makah Tribal Council.

Laws and regulations are enforced under the provisions of the Makah Law and Order Code. The Makah Law and Order Code establishes a tribal court, defines its jurisdiction, provides for tribal police, details the selection and procedures for judges and juries, and includes a criminal code and procedures for criminal and civil actions. If NMFS authorizes a gray whale hunt, the Tribe proposes to adopt laws and regulations to enforce NMFS' regulations governing the hunt.

3.1.2.1 Makah Tribal Departments, Agencies, and Commissions

The Makah Tribal Council oversees the operations and management of approximately 14 governmental departments and 6 tribally chartered organizations including the Makah Whaling Commission (Makah Tribe 2022a). The departments, chartered organizations, and the Makah Whaling Commission are as follows:

Makah Social Services comprises five programs: Domestic Violence Program, Low Income Home Energy Assistance Program, Family Services Program, Senior Citizens Program, and United States Department of Agriculture Food Distribution Program.

Makah Education and Training provides services to tribal/community members for higher and vocational education and the Workforce Investment Act program, i.e., funding, work placements, employment and training, and clothing vouchers.

Makah Realty protects and promotes the trust assets (realty and physical property) of the Makah Tribe and the tribal membership.

Office of the General Manager oversees and provides leadership for all departments for the Makah Tribe. The Office of the General Manager also oversees the operations of the Tribe for essential and basic health, legal concerns, transportation, and community beautification.

Makah Tribal Court provides a forum for resolving disputes that is consistent with applicable governing laws and in keeping with the traditional and cultural values of the Makah Tribe. The Makah Tribal Court provides judicial services within the jurisdiction of the Makah Tribe involving criminal actions, civil actions and juvenile matters to include: criminal offenses, adult probation, civil disputes, child dependency cases, juvenile offenders and Makah Healing Court (adult drug court). The Makah Tribal Court Administration also

provides oversight to the Makah Victim Services program and facilitates the Makah Domestic Violence Task Force and Protocol.

Makah Housing Authority builds, rehabilitates, and weatherizes homes; acquires land for neighborhood revitalization development; and develops local capacity to provide these services.

Makah Human Resources promotes an effective and efficient work environment for the employees of the Makah Tribe.

Makah Community Gym promotes wellness in the community through planned events, youth programs, and making exercise facilities available to all. The Boys & Girls Club of the Makah Tribe is managed by the Community Gym Manager.

Makah Early Childhood Education runs the Head Start/ Early Head Start program to prepare preschool-aged kids and younger for school, and runs childcare services that are used by many members of the Neah Bay community.

Sophie Trettevick Indian Health Center provides primary medical care and dental services. The clinic is open Monday through Friday, from 8:00 a.m. to 5:00 p.m., with emergency service available via 911, 24 hours a day, 7 days a week. Emergency medical situations are addressed by providing stabilization and transport to the nearest appropriate facility. Airlift Northwest (Seattle) can be called in, based on emergency medical technician and/or provider determination. If Airlift Northwest is not available, the Coast Guard may provide transport. The Coast Guard responds to open-water-related emergencies. Although the health clinic provides day-to-day care service to tribal members, it will treat anyone with life- or limb-threatening injuries. Such injured non-Indians are treated to stabilize their injuries and then transported to an appropriate facility. The facility has a memorandum of agreement with Clallam Bay Fire District 5 to provide mutual assistance in emergency situations.

Makah Forestry establishes and develops policies to guide management of the forested lands of the Makah Indian Reservation and serves as a basis for decision-making by Makah Natural Resources Departments and the Makah Tribal Council.

Makah Public Safety departments include the Police Department, Corrections, Communications, Adult Probation, Natural Resources Enforcement, Emergency Medical Services, Fire Department, Animal Control, and Emergency Management. Police officers are responsible for tribal law and ordinance enforcement and public safety. Natural resources enforcement officers are responsible for enforcing hunting, fishing, and forest products

permits/regulations. They are trained law enforcement officers who can supplement the Police Department officers, as needed. The Fire Department consists of full-time employees and trained volunteers to run engines and aid cars to respond to fires and other emergencies. Emergency Medical Services provide emergency medical care 24 hours per day to residents and visitors to the Reservation. Emergency Management provides infrastructure and plans for response to catastrophic events (e.g., tsunamis).

Makah Planning (Community Planning and Economic Development) provides integrated, comprehensive, and traditional planning support to the Makah Tribal Council in decision-making concerning economic and community development.

Makah Fisheries Management is responsible for protecting, sustaining, and enhancing the relationship between the Makah Tribe and the many aquatic species that play a vital part in the Tribe's cultural and economic well-being. Makah Fisheries Management manages more than 20 different fisheries within the Tribe's U&A. The fisheries target a wide variety of fish species, use diverse gear types, and span seasonal time periods throughout the entire year. Makah Environmental Division, which is located within Makah Fisheries Management, includes Treaty Reserved Rights Protection, Environmental Planning, Environmental Health, Air Quality, Water Quality/Resources, and Environmental Education.

Makah Whaling Commission. The Makah Tribal Council first adopted the Charter of the Makah Whaling Commission in 1996 with Resolution 10-97, and amended it in 2001 with Resolution 100-01. The Commission is organized around the traditional heads of Makah families for the purpose of advising and making recommendations to the Makah Tribal Council regarding "rules and regulations to govern the conduct of treaty ceremonial and subsistence whaling," and "the administration and enforcement of such regulations, and [the] conduct[ing of] educational programs and research relating to ceremonial and subsistence whaling" (Makah Whaling Commission Charter 2001). The Makah Tribal Council considers the Whaling Commission's recommendations regarding tribal regulations and tribal permits authorizing the conduct of treaty ceremonial and subsistence whaling.

The Whaling Commission confirms that the whaling captain and crew have met the training guidelines and other applicable requirements for a permit. The Whaling Commission issues whaling permits which must then be approved by the Makah Tribal Council. The tribal whaling permit is issued to the whaling captain. It identifies the whaling captain, date issued, vessels involved, names of crew members, and area where the hunt is authorized. The permit must incorporate all of the requirements of the Tribe's management plan and any additional

requirements the Whaling Commission and the Tribal Council deem appropriate. It also must identify conditions that will result in its termination. For example, landing of a gray whale, striking and losing a gray whale, expiration of the permit after 10 days (without a strike or landing), and termination by the Whaling Commission or Tribal Council.

Makah Finance Department provides administrative financial services to the Tribe, including complying with applicable federal, state, and local policies; ensuring effective financial, personnel, procurement, and property management; promoting the highest standards of integrity, impartiality, and professionalism (in conduct of administrative programs); and promoting effective coordination and improved management practices among tribal programs, the Makah Tribal Council, enterprises, and outside agencies.

Tribal Enterprises. There are several separately chartered enterprises: Makah Business Enterprises, Makah Forestry Enterprise, Makah Cultural and Research Center, and Port of Neah Bay/Makah Marina. Makah Business Enterprises "operates within the structure of the Tribe." The other entities operate under independent boards (appointed by Makah Tribal Council).

- **Makah Business Enterprises** is responsible for creating and enhancing a for-profit sector for the betterment of the Makah tribal community. The businesses operating under Makah Business Enterprises are intended to generate profits, develop self-sufficiency, and create employment. As of 2012, five businesses operate under Makah Business Enterprises: Makah Mini-Mart/Fuel Station, Hobuck Beach RV and Cabin Resort, Cape Resort and RV Park.
- **Makah Forestry Enterprise** focuses on sustainable timber harvests while marketing logs and other forest-related products.
- **Makah Cultural and Research Center** is a nonprofit organization dedicated to revitalizing and preserving Makah culture. Its operations include an archive and research library, a museum, an education department, a language program, and a Tribal Historical Preservation Department that manages cultural properties on the Reservation.
- **Port of Neah Bay** operates the Makah Marina, Marina Conference Center, and the Makah Office of Marine Affairs. The Port manages contracts with two oil spill response contractors to provide 24-hour response coverage and oversees the Big Salmon Fishing Resort lease. The Port's mission is to develop, construct, regulate, and operate facilities and infrastructure for the transportation and industrial needs of the Makah Reservation to create profitable opportunities for tribal and individual businesses through project revenues, bonds, grants, and other sources.

- **Makah Dock**: the mission of the Makah Dock is to provide sustainable support to the commercial fishing fleet while maintaining the assets of the Makah Tribe. There are two permanent fish buyers and activities of the Dock include: fish buying, ice delivery, floor ice, hoist and forklift services and staging services for oil spill response organizations. The Makah Dock's revenue is generated from ice sales, staging fees, forklift and crane services and offload fees.

3.1.2.2 Makah Tribal Programs and Management Plans

Through the Makah Tribal Council and tribal departments, the Makah Tribe operates numerous governmental programs under a variety of management plans. Those most relevant to this FEIS are described below.

3.1.2.2.1 Makah Public Safety Program

In addition to weapons training, police officer training includes advanced narcotics training, forensics, and critical incident management. In 2005, the Makah Tribal Council adopted the National Management Incident System for response to emergencies that may affect the tribal community. Most emergency situations are handled locally, but major incidents may require assistance from state, county, or federal authorities. The National Management Incident System was developed to better coordinate responders from different jurisdictions and disciplines in the event of natural disasters and emergencies, including acts of terrorism. Benefits include a unified approach to incident management; standard command and management structures; and emphasis on preparedness, mutual aid, and resource management. The website is http://www.fema.gov/emergency/nims/index.shtm.

Using the National Management Incident System template, the Makah Tribal Council adopted an integrated comprehensive emergency plan in 2005. The plan provides for coordinated response and unified command structure under the Makah Director of Public Safety (Police Chief). The handling of any emergency, including civil disturbance, falls under the plan. One example of the plan's implementation occurred in December 2005, when there was a water shortage emergency on the reservation because of a combination of unusual drought and storm damage. In response to the emergency, the Police Chief sought a Makah Tribal Council declaration of emergency, which placed the comprehensive emergency plan in effect. Another example was in July 2010, when the Tribe hosted the Tribal Journeys event and the incident command system used border patrol, state, and other Tribal agencies.

3.1.2.1.1 Makah Fisheries Management Department

Fisheries in Puget Sound, the Strait of Juan de Fuca, and nearshore coastal waters are co-managed by the Indian treaty tribes and the Washington Department of Fish and Wildlife (WDFW). Ocean fisheries in United States waters of the Makah U&A are regulated by the PFMC with NMFS oversight and approval under the Magnuson-Stevens Act. State and tribal biologists participate in developing the scientific information that guides the decision-making and deliberative processes of the PFMC and NMFS. Harvest of salmon is also governed internationally under the 1985 Pacific Salmon Treaty, developed through cooperation by tribes, state governments, United States and Canadian federal governments, and sport and commercial fishing groups. The treaty is implemented by the eight-member bilateral Pacific Salmon Commission, which includes representatives of federal, state, and tribal governments. The Pacific Salmon Commission does not regulate salmon fisheries, but provides regulatory advice and recommendations, and is a forum for the two countries to reach agreement on mutual fisheries issues.

The Makah Tribe regulates and coordinates its own fishery management program within its U&A following the guidance of the Makah Ocean Policy (Makah Tribe 2017). The Tribe manages fisheries for salmon, halibut and other bottom fish, rockfish, Pacific whiting, black cod/sablefish, shellfish, and other marine species off the Washington coast, in coastal rivers and bays, and in the Strait of Juan de Fuca.

According to the Makah Fisheries Management 2022 Annual Report (Makah Tribe 2022b), the following divisions and programs are under Makah Fisheries Management:

Groundfish Management Program. The Program's primary goal is to protect the Makah Tribe's treaty rights through sustainably managing marine fisheries with emphasis on environmental, economic, and social aspects. The Groundfish Management Program manages the following Makah treaty fisheries: long-line black cod (sablefish) fishery; bottom trawl fishery; mid-water trawl yellowtail rockfish-directed fishery; Dungeness crab pot fishery; Pacific halibut long-line fishery, and mid-water trawl Pacific whiting fishery. Management activities include: participation in international, federal, state, and tribal management forums and processes, including the International Pacific Halibut Commission, the Pacific Whiting Treaty Joint Management Committee, and the PFMC development and implementation of Makah management measures to preserve the resources, allow harvest of target species, and minimize bycatch; promulgation and issuance of regulations; observing, monitoring, and sampling the catch; and development of new fisheries.

Salmon Management Program. The Program's primary goal is to increase harvest opportunities of salmonids for Makah tribal fishermen while protecting, conserving, and enhancing salmonid stocks. The salmon management program manages the following Makah salmonid fisheries: ocean troll fishery, Strait of Juan de Fuca troll fishery, Strait of Juan de Fuca drift gillnet fishery, Strait of Juan de Fuca setnet fishery, and on-Reservation river fisheries. Management activities include participation in international, federal, regional, state, and tribal management forums and processes, including the Pacific Salmon Commission, North of Falcon process, and the PFMC.

Marine Mammal Program. Program staff is responsible for researching and participating in scientific and management forums regarding marine mammals, which are important biological and cultural resources within the Makah U&A. The Tribe's Marine Mammal Biologist attends and participates in the meetings of the International Whaling Commission (IWC) Scientific Committee and its subcommittees and the Pacific Scientific Review Group, which provides advice to NMFS and USFWS on marine mammal stock assessments and review of sources of mortality. In addition to these activities, the Marine Mammal Program conducts whale research, including research on gray and humpback whale life history through photo-identification and stock structure through the collection of biopsy samples. In addition to whale research, the Program's research projects have investigated a wide range of topics resulting in publications in peer-reviewed scientific journals. The Program is an active member of the regions stranding and whale disentanglement networks and monitors marine mammal strandings in the Makah U&A. The Program also has education and outreach functions including coordinating internships for Makah youth on fisheries and environmental science (https://mfminterns.home.blog) and conducting presentations in classrooms in Neah Bay and other schools in the region. The Program's activities can change and expand depending on the availability of grant funding.

Marine Ecology Program. The program addresses emerging issues that can affect treaty resources and rights. Recent issues addressed include a rapid increase in invasive European green crabs, evaluating the transmission of harmful algal bloom toxins within the ecosystem, and participating in work groups on ocean acidification and climate change. The program conducts monitoring of the nearshore ecosystems to establish baseline population numbers and distributions. The program also assists in research activities conducted by other programs within the department.

Scientific Research Program. The primary objective of this program is to conduct scientific research to solve management problems at the request of Makah Fisheries Management managers. Since 2000, the program has used stable isotope analysis to investigate questions on

fish early life history, population structure, migration, and climate change. This research has resulted in about 40 publications in national and international scientific journals.

Hatchery Operations Division. The hatchery operations program raises and rears six salmonid stocks, including two stocks of steelhead, two stocks of Chinook salmon, coho salmon, and sockeye salmon. The goals of the program are to: provide harvestable steelhead, coho salmon, and Chinook salmon for tribal and sport fishers; provide coded-wire tagged Chinook salmon smolts for the U.S./Canada wild Chinook salmon indicator stock study; increase the range and abundance of Hoko River Chinook salmon; increase the range and abundance of Lake Ozette sockeye salmon; and provide assistance with various salmon research and monitoring projects.

Environmental Division. The primary objective of the Environmental Division is to protect air, marine nearshore, freshwater, and terrestrial environments and resources for ecosystem health and human use. This objective is achieved through the Division's Air Quality Program, Water Quality Program, and Land and Solid Waste and Environmental Health Program. The Division also plays an active role in engaging and monitoring international, national, regional, and local forums on environmental issues affecting the Makah Tribe.

Habitat Division. The primary goal of the Habitat Division is to protect and restore freshwater aquatic resources on the Makah Reservation and within the Makah U&A. Principal activities of this division include participating with other tribal departments regarding planning, development, and resource extraction projects that affect freshwater resources; participating in habitat enhancement with WDFW under the State of Washington Forest Practices Act; identifying, prioritizing, and implementing habitat rehabilitation projects benefiting aquatic habitat on the Makah Reservation and in the U&A; participating in recovery efforts of Lake Ozette sockeye salmon; and developing watershed planning and protection efforts with adjacent communities to protect aquatic resources on the Makah Reservation and U&A.

Salmon Field Research and Monitoring Program. This program of the Habitat Division conducts field research and data collection on local salmon stocks for use in fishery management, stock assessments, and evaluation of salmon recovery programs. Many of the division's projects are ongoing projects with long-term data sets that can be used to assess population trends over many years. The division's main project areas are Lake Ozette sockeye monitoring, coho smolt out-migration monitoring, adult spawner surveys, and coded wire tag recovery.

3.1.2.2.2 Makah Comprehensive Economic Development Strategy

The Makah Tribe's Comprehensive Economic Development Strategy (Makah Tribe 2006b) identifies the Makah Tribal Council as the approving body for economic development within the reservation. The Makah Tribe obtains most of its tribal income through marina and harbor development, Makah Forest Enterprise, and the Makah Business Enterprises.

Goals identified within the plan include the following:

- Determine the feasibility of and priority ranking for seven projects associated with marina and harbor development (marina expansion, haul-out facility, upgraded marine fuel float [for large vessels in the fishing fleet], aquaculture, log dump expansion, Neah Bay Harbor deep-water entry, and cruise ship facility).
- Develop a small business program for ancillary businesses that support, enhance, and fulfill needs associated with the new marina.
- Expand the forested land base for the Tribe.
- Study the feasibility of a marine fish hatchery.
- Provide academic and business training and education.
- Diversify the Makah fishing industry, specifically the whiting fishery.
- Identify new projects consistent with the Makah Tribal Land Use Committee, including a visitor center (that may be associated with an ocean-front cabin resort and motel), road improvements, boardwalk (walking paths on beach side of downtown), trails for tsunami escape ways, walking path, and a new development area that would provide a wellness/medical center, senior citizen apartments, clinic staff housing, baseball fields, and new Makah Tribal Council offices.

Other priorities included in the plan are a new clean water source for tribal use, projects that provide for downtown revitalization, Shi Shi Trail expansion, tribal communications network upgrades, a potential wind generation development, and opportunities to provide value-added seafood processing.

3.1.2.1.2 Makah Living Forest Management Plan

The Makah Living Forest Management Plan (Makah Tribe 2009) identifies goals and objectives for maintaining a desired future condition for the Tribe's forest resources. The intent of the forest plan is to guide harvest of mostly second-growth timber while allowing for harvest of only small, scattered pockets of older timber (exceeding 100 years of age) in an attempt to keep the remaining, large, contiguous blocks of older timber intact. Annual harvests of 8.5 million board feet are expected to achieve this goal, while providing for a long-term sustainable timber harvest

level. Approximately 23,437 acres (78 percent of the reservation) are managed for timber harvest. The Tribe has also acquired, and continues to acquire, land off the Reservation for forest management.

3.2 Water Quality

3.2.1 Introduction

The following section describes the management and existing condition of water resources in the action area. Topics addressed include drinking water sources, shellfish harvest areas, and existing practices for the prevention of and response to spills of fuel and other contaminants. This section also addresses solid waste disposal as it relates to options for disposal of a whale carcass. Ocean currents and nearshore mixing are discussed in Section 3.3 (Marine Habitat and Species).

3.2.2 Regulatory Overview

The federal Clean Water Act (33 USC 1251 *et seq.*) establishes standards and regulations for protecting the quality and beneficial uses of the nation's waterways and regulates navigable waters of the United States. Federal agencies responsible for enforcing the Clean Water Act include EPA and the Army Corps of Engineers. On the Makah Reservation, EPA has delegated authority under sections 303(c) and 401 (both water quality standards and implementation plans and dredge and fill permits) of the Clean Water Act to the Makah Tribe. On the Makah Reservation, Makah Health Code Title III states that "it shall be a violation [of the Health Code] to conduct activities in the watershed which may degrade the physical, chemical, microbiological, viral, or radiological quality of the source of supply." All proposed activities require a written permit from the Tribal Council. EPA has retained some authority over Clean Water Act management on the Makah Reservation and administers programs such as the National Pollutant Discharge Elimination System under section 402.

Off the Makah Reservation, EPA has delegated authority over state waters (including sections 401 and 402) to Ecology, which is responsible for the implementation of the Washington State Water Pollution Control Act (RCW 90.48). This law is intended to maintain the highest possible standards for all waters of the state consistent with public health and enjoyment; the propagation and protection of wildlife, birds, game, fish, and other aquatic life; and prevention and control of pollution within waters of the State of Washington. Ecology has set water quality standards to protect the beneficial uses of surface waters. Ecology has established fresh and marine water quality standards for fecal coliform bacteria (an indicator of fecal contamination); dissolved oxygen; total dissolved gas; temperature; pH; turbidity; aesthetics; and toxic, radioactive, and deleterious materials (WAC 173-201A-210).

Ecology routinely collects marine water quality data as part of the long-term Marine Waters Monitoring Program initiated in 1967. Ecology uses these long-term data to assess marine water quality in Washington State, including coastal estuarine areas represented by Willapa Bay and Grays Harbor (Ecology 2012a). The agency uses these data to differentiate inter-annual and seasonal variations from those resulting from human activities at specific locations. Ecology uses the data primarily to maintain the federal Clean Water Act 303(d) list of impaired waterbodies throughout the state, and 305(b), the report describing the overall status of the waters of the state.

3.2.3 Existing Conditions

The primary saltwater resources in the action area include the Pacific Ocean from the mouth of the Strait of Juan de Fuca to the EEZ boundary and the western portion of the Strait of Juan de Fuca that includes the Makah Tribe's U&A (Figure 3-1). The EEZ extends up to 200 miles (321.9 km) offshore, and coastal states have the right to explore, exploit, and manage within its limits. Freshwater resources in the action area occur in portions of Water Resource Inventory Areas 20 (Soleduck-Hoh) and 19 (Lyre-Hoko), and portions of the Makah Reservation fall within both. Major rivers include the Wa'atch and Sooes Rivers, the two main tributaries that drain into Makah Bay from the Makah Reservation, as well as the Ozette River, which runs from Ozette Lake to the nearshore area of the Olympic National Park (Figure 3-2). These rivers all occur in Water Resource Inventory Area 20. Numerous additional smaller streams in the action area drain to the Pacific Ocean, the Strait of Juan de Fuca, and Neah Bay. Based on information Ecology provided, these waterbodies have extraordinary water quality, and none of the designated uses (shellfish harvesting, primary contact recreation, wildlife habitat, harvesting, commercial navigation, boating, and aesthetics) is restricted (WAC 173-201A-210).

Ecology implements marine water quality management activities in Puget Sound and the outer coastal estuaries based, in part, on periodic quantitative water quality monitoring data. The data are also used for interdisciplinary efforts aimed at assessing the health of marine ecosystem components, ranging from eelgrass to salmon, because these organisms live in and are affected by marine water and its quality.

Ecology has not listed the Pacific Ocean, the Strait of Juan de Fuca, Neah Bay, or any of the rivers and streams within the action area as impaired for water or sediment quality parameters. These parameters generally include temperature, dissolved oxygen, pH, nutrients, bacteria, metals, and toxic substances (WAC 173-201A-210). In addition, Ecology and the Washington Department of Health have monitored for fecal bacteria through the BEACH program at six beaches in the Makah U&A: Dakwas Park Beach, Front Street Beach, East Hobuck Beach, Sooes

Beach, Third Beach, and Warmhouse Beach (Figure 3-2). Of the nearly 2,500 samples taken between 2010 and 2013, fecal bacteria levels (*Enterococcus*) exceeded the EPA's water quality limits on just 35 occasions with half of these from sampling sites at Dakwas Park Beach in Neah Bay (Ecology 2013a).

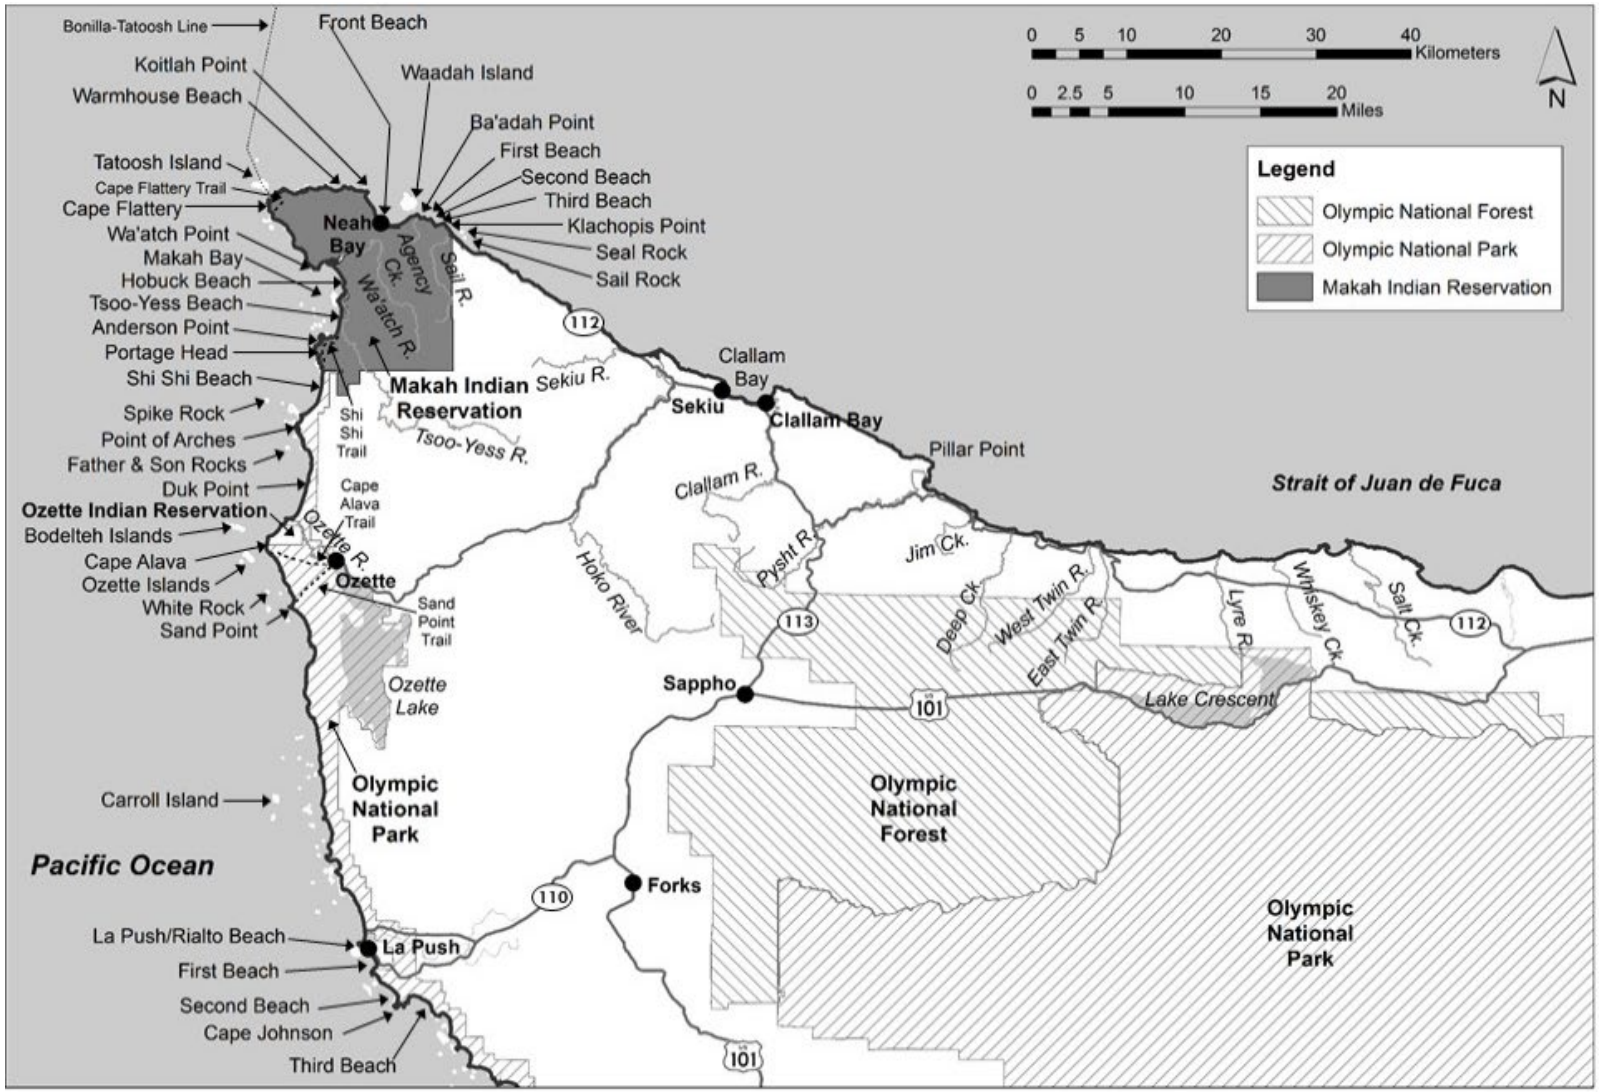

Figure 3-2. Topographic features of interest.

3.2.4 Drinking Water Sources

Drinking water sources for the Makah Reservation (with three primary settlement areas) are local rivers and the Educket Reservoir (United States Bureau of Reclamation 2006). In 2006, a drought resulted in the Makah Tribal Council issuing a state of emergency for Neah Bay. During this time, the Tribe depended on the U.S. Army to provide water to the reservation via a diesel-powered desalinization system. The Bureau of Reclamation is considering the following options for increasing the availability of drinking water for current use and planned growth:

- Reclamation of Educket Reservoir;
- Development of an additional collection system from three creeks along Cape Flattery;
- Construction and operation of a reverse osmosis desalinization plant that would collect water from the Wa'atch River intertidal zone south of the existing tribal center through an underground collection system near the outlet of the Wa'atch River.

3.2.5 Shellfish

The Washington Department of Health regularly monitors shellfish areas because shellfish tend to accumulate pollutants and generally reflect long-term (chronic) water quality concerns (Washington State Department of Health 2012a). This information supplements the periodic samples Ecology takes at discrete water quality monitoring stations. The state Surface Water Quality Standards also contain criteria to reduce the chance of people becoming ill from eating shellfish or from swimming or wading in waters of the state. Makah Fisheries and the Makah Port Authority also monitor shellfish for contamination. Managers can close shellfish beds to human harvest for three reasons: the presence of human fecal coliforms (typically from failing septic systems), fuel releases, and toxic algal blooms. Fecal coliforms are used as indicators of contamination. Although generally not harmful themselves, they indicate the possible presence of pathogenic (disease-causing) bacteria, viruses, and protozoans that live in the digestive systems of humans and other animals (EPA 1997). Toxins associated with algal blooms include domoic acid, saxitoxin, okadaic acid, and gonyautoxin derivatives. These naturally occurring neurotoxins may be harmful if consumed in significant concentrations, which can occur when people eat crabs or shellfish that have accumulated toxins by feeding on toxic algae.

In 2008, the Washington Department of Health conducted a Sanitary Survey of Neah Bay (Washington State Department of Health 2008). This survey is conducted as part of a routine 12-year evaluation of the Neah Bay commercial shellfish growing area. Shoreline survey information and water quality data indicated that Neah Bay meets the criteria for an Approved classification. A prohibited area was established to accommodate the marina/moorage area and an unclassified

area exists in the northwest portion of the bay. The Sanitary Survey also noted that the major potential sources of pollution in Neah Bay include the overboard discharge of sewage by boats, stormwater, and animals. However, none of these were cited as having had a significant adverse impact on water quality in Neah Bay and the survey noted that elevated bacteria levels in water samples are infrequent and random (except for one site in the prohibited area adjacent to the marina).

In addition to the Neah Bay site, the Washington Department of Health has also mapped an approved commercial shellfish bed in Makah Bay. These are the only two approved commercial shellfish beds within the action area (Washington State Department of Health 2022). Both have been listed as inactive since 2020 due to lack of harvest activities (Washington State Department of Health 2021a and 2021b). Subsistence shellfish gathering takes place at Neah Bay, Makah Bay, and other relatively rocky areas on the reservation. Butter clams, steamer clams, and cockles are gathered on the west and east ends of Neah Bay. A horseclam bed occurs on Front Beach, near where the gray whale was landed in 1999. A pilot project by Makah Fisheries Management with geoduck aquaculture is also underway on Front Beach. Additional species, such as mussels, are gathered in intertidal rock areas throughout the reservation.

In general, the beaches located within the action area are hotspots for algal blooms, at least partially because of the nutrient-rich waters and mixing that occur at the mouth of the Strait of Juan de Fuca (WDFW 2004). Algal blooms are triggered by a complex interaction of environmental conditions, and the duration and timing of closures are difficult to predict. The most recent closure in Neah Bay was due to saxitoxin in August of 2022. Levels remained high for several months and shellfish gathering was reopened in October 2022. In order to reopen, levels must remain below the closure level of 80 micrograms per 100 grams for two concurrent weeks. Closures, while hard to predict, typically occur in the spring – summer months when phytoplankton diversity increases and populations bloom. Different species of shellfish hold onto toxins at different rates which may result in extended closures (E. Miller, Makah Tribe Water Quality Specialist, pers. Comm., March 17, 2023). The most recent review of fecal coliform samples by the Washington Department of Health classified both Makah Bay and Neah Bay as meeting the water quality standards of the National Shellfish Sanitation Program of the U.S. Food and Drug Administration (Washington State Department of Health 2021a and 2021b).

3.2.6 Spill Prevention

The action area includes national and international shipping lanes and is open to recreational boating and commercial and recreational fishing. Wherever marine vessels are present, there is a

risk that pollutants from boat emissions and/or spills will enter the water. However, as discussed above, Ecology has not listed any of the waters of the action area as impaired for water or sediment quality parameters; however, some impairment of marine waters has occurred during major spill events.

The Washington State Department of Ecology maintains a list of organizations that are prepared to respond to emergency spills in Puget Sound, the Strait of Juan de Fuca, and off the Washington coast (Ecology 2022a). As part of Ecology's Spill Prevention, Preparedness, and Response Program, it stations a rescue tug in Neah Bay seasonally to assist tankers and cargo ships that are drifting or need support during bad weather (Ecology 2023). In general, these pollutants (such as hydrocarbons) are associated with gasoline and diesel engines used by transiting vessels, and they enter the environment from spills and/or exhaust. Smaller oil spills could occur during fueling and maintenance operations at docks.

The nearshore portion of the Makah U&A corresponds largely with the designated area to be avoided for the OCNMS. This designation is meant to reduce the potential for catastrophic oil spills by encouraging big ships (carrying large amounts of bunker fuel) to avoid the nearshore areas of the coast. While this designated area does not encompass the entire OCNMS, its boundaries protect sanctuary resources most at risk from vessel casualties, while being compatible with existing vessel traffic lanes (Galasso 2000). See Subsection 3.1.1.1.3, Olympic Coast National Marine Sanctuary, Current Issues, Area to be Avoided, and Subsection 3.13.2, Transportation, Regulatory Overview.

3.2.7 Solid Waste Disposal

Until 2012, there was a landfill at Neah Bay (the Warmhouse Beach dump site) used by U.S Air Force (USAF), U.S. Navy, U.S Army, Bureau of Indian Affairs (BIA), Indian Health Services (IHS), and the Makah Tribe for disposal of solid and hazardous waste for at least 40 years. The facility, under the jurisdiction of the Makah Tribal Council, was the only landfill in Clallam County that accepted municipal solid waste (Parametrix 2007). In the 1980s, a solid waste management plan for the Makah Reservation recommended closure of the dump site and construction of a transfer station to haul waste to the closest permitted disposal facility (Paul S. Running and Associates 1983). Previous reports indicate that materials disposed by the USAF included paint cans, paint, paint thinner, pesticides, lubricants, waste oil, asbestos-containing materials, and sewage sludge (Tecumseh 1997). Items identified in the dump include batteries, tires, appliances, construction materials, car bodies, glass, and hypodermic needs (White Shield 1995). Contaminants found in environmental samples at the Warmhouse Beach Dump and in the

creeks include polycyclic aromatic hydrocarbons (PAHs), polybrominated diphenyl ethers (PBDEs), polychlorinated biphenyls (PCBs), dioxins and furans, perchlorate, pesticides, metals, and asbestos. Mussels from Warmhouse Beach were found to contain elevated concentrations of lead. A comprehensive solid waste management plan update prepared for Clallam County indicated that siting a new municipal solid waste landfill in Clallam County is not feasible because of various factors, including climate, geography, land use, and the availability of a lower-cost option to export waste (Parametrix 2007).

In the fall of 2012, the Tribe opened a solid waste transfer station in Neah Bay and closed the Warmhouse Beach dump site (Greene 2013). The Makah Transfer Station includes a number of features aimed at recycling and sustainability, including sites to collect recyclable materials (e.g., paper, metal, and plastic) and collect hazardous wastes for proper disposal, and natural stormwater controls that capture water and filter sediments in natural vegetated swales and channels before allowing it to seep into the adjacent wetlands (Ridolfi 2013). Waste from the Makah Transfer Station is eventually transported in containers via truck and railway to the Roosevelt Landfill in Klickitat County, Washington (J. Garcelon, Clallam County Environmental Health Specialist, pers. Comm., November 27, 2013).

In response to a petition from the Tribe, the U.S. Environmental Protection Agency (EPA) added the Warmhouse Beach dumpsite to the General Superfund section of the National Priorities List on December 12, 2013 (78 FR 75475). The Makah Tribe considers cleanup of the dump of highest environmental priority (EPA 2013). This listing allows the EPA to utilize funds under the Comprehensive Environmental Response, Compensation, and Liability Act to clean up the site. Since the listing in 2013, the EPA has undertaken a remedial investigation in collaboration with the Makah Tribe to understand the nature and extent of the contamination at the site and to assess the associated risks to human health and the ecology. Once the level of risk is determined, a feasibility study can be undertaken to identify and compare cleanup alternatives (EPA 2021).

Given that the Warmhouse Beach site is now closed, it is highly unlikely that any whale carcass remains would be brought there for disposal. It is possible that some remains could be brought to the new transfer station; however, this too is unlikely given the high costs of shipping to a landfill. The Tribe may choose to allow unused portions of the whale carcass to decompose at the beach landing site or at other land-based sites, especially if there was interest in retrieving the whale bones after natural decomposition had made them more suitable for handicraft. It is most likely that whale carcass remains would be disposed of in deep marine waters of the Strait of Juan de Fuca or the Pacific Ocean. Doing so would lessen the chance for adverse water quality impacts

in nearshore waters (e.g., impairment of shellfish growing areas) as well as in the vicinity of the transfer stations (e.g., via decomposition and seepage).

The two primary generators of animal carcasses in Clallam County are the Humane Society (in Port Angeles) and Battelle Marine Sciences Laboratory (near Sequim). Both organizations use Petland Crematorium in Aberdeen for cremation of animals. Battelle sends hazardous carcasses to Pacific Marine Laboratory for disposal. The Clallam County Road Department buries roadkill carcasses at remote locations on public lands scattered throughout the county (Parametrix 2007).

3.3 Marine Habitat and Dependent Species

3.3.1 Introduction

The entire range of the ENP gray whale stock is vast and crosses many large marine ecosystems, including the Pacific Central American Coast, California Current, Gulf of Alaska, and Bering and Chukchi Seas (Longhurst 2006; Sherman and Alexander 1989). The action area is located within a coastal transitional zone between the Gulf of Alaska and the California Current large marine ecosystems (Sherman and Alexander 1989; Longhurst 1998). These ecosystems are largely defined by the splitting of the North Pacific Current into two broad coastal currents as it encounters the U.S./Canada west coast: the north-flowing Alaska Current and the south-flowing California Current (see Figure 3-1). Within the California Current Province, scientists regularly study and predict physical and biological features and processes in the northern California Current ecosystem, which is generally described as extending from northern California to Vancouver Island (e.g., Field et al. 2001; Field et al. 2006; Hickey and Banas 2008; Sydeman and Elliott 2008; Harvey et al. 2017; Wells et al. 2017), though some studies extend only to the U.S.–Canada border in the north because of differing management regimes between the two countries (Field et al., 2001; Field et al., 2006).

Some whales from the ENP stock forage seasonally in the semi-enclosed inland waters of Washington State and British Columbia, an area collectively known as the "Salish Sea." As described below in Subsection 3.4.3.4, Pacific Coast Feeding Group (PCFG) of Gray Whales, some PCFG whales forage during the summer/fall in the westernmost part of the Salish Sea (in the Strait of Juan de Fuca). Additionally, each spring a small number of whales from the ENP stock break off from the northward migration to feed for 2-3 months in isolated areas of North Puget Sound. Therefore, we have included information about the Salish Sea in this chapter to clarify its overlap with the action area and the potential for the action alternatives to have indirect effects on resources in these waters.

Thus, the action area is associated with the confluence of three marine ecosystems: the Gulf of Alaska, California Current, and Salish Sea. For purposes of our MMPA analysis, we took a precautionary approach of examining the impact of the proposed waiver and regulations at an ecosystem scale commensurate with the action area – specifically the northern California Current and Salish Sea ecosystems. These are the smallest recognized marine ecosystems of which ENP gray whales are a part, and, combined, they encompass the entire Makah U&A. The proposed hunt area on the outer Washington coast lies within the U&A.

The marine environment off the coast of Washington is highly energetic, productive, and dynamic, supporting a wide range of invertebrates, fish, and marine wildlife. The ecological importance of the habitat was acknowledged in the OCNMS designation (NOAA 1993). High biological productivity, diversity of habitats, the wide variety of marine mammals and birds living in or migrating through the area, and the presence of endangered and threatened species and essential habitats were identified as some of the biological resources giving the Sanctuary particular value (refer to Subsection 3.1.1.1, Olympic Coast National Marine Sanctuary, for more detail). The dynamic physical processes and high levels of disturbance experienced along the Washington coast, including the action area, affect ecosystem structure, ecological interactions, and species' recruitment dynamics. Understanding the physical processes in the action area will inform the analysis of potential direct and indirect effects to the ecosystem from activities associated with the proposed whale hunt.

The description of the marine ecosystem that follows is organized by pelagic environment (open water column) and benthic environment (bottom substrata), identifying physical features and processes and biological resources associated with each environment. ENP gray whales and other marine wildlife in the action area are described in more detail in other sections (Section 3.4, Eastern North Pacific Gray Whale, and Section 3.5, Other Wildlife Species).

3.3.2 Regulatory Overview

The conservation, preservation, and management of marine habitat and biological resources in the action area occur under several statutory and regulatory authorities, the most pertinent of which are detailed below.

Under federally granted Coastal Zone Management Act authority, Ecology administers Washington State's Coastal Zone Management Program on the state's shoreline (under the Shoreline Management Act) and waters (under the Aquatic Management Act), except for excluded federal lands (i.e., lands that the federal government owns, leases, or holds in trust, such

as the Olympic National Park coastal strip and the Makah and Ozette Reservations, and other lands the use of which is subject to the sole discretion of the federal government).

Under the National Marine Sanctuaries Act and regulations, marine plants and algae, invertebrates, plankton, and fish are protected and conserved as Sanctuary resources within the boundaries of the OCNMS. Federal designation and management of the OCNMS and protection of Sanctuary resources by NOAA's National Marine Sanctuaries Program under the National Marine Sanctuaries Act, including protection and management of habitat such as bottom formations and substratum, is described above in Subsection 3.1.1.1, Olympic Coast National Marine Sanctuary. Federal designation and management of the rocks and islands that compose the Washington Islands National Wildlife Refuges are also described above in Subsection 3.1.1.2, Washington Islands National Wildlife Refuges.

The PFMC and NMFS are the primary federal management authorities for managing and conserving living marine resources, including marine fish and plants, out to 200 miles (322 km) from shore under the Magnuson-Stevens Act and the North of Falcon planning process. Northwest Indian tribes and WDFW also participate in fisheries management. Under the Magnuson-Stevens Act, NMFS and the PFMC also protect habitat identified as essential for commercially important fish species. Essential fish habitat is defined under the Magnuson-Stevens Act as "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity" (16 USC 1802 Section 3(10)). Regulatory guidelines elaborate that the words 'essential' and 'necessary' mean that essential fish habitat should be sufficient to "support a population adequate to maintain a sustainable fishery and the managed species' contributions to a healthy ecosystem." The PFMC describes essential fish habitat in its fishery management plans, minimizes impacts to essential fish habitat resulting from fishing activities, and consults with NMFS about activities that might affect essential fish habitat. The Council may use fishing gear restrictions, time and area closures, harvest limits, and other measures to lessen adverse impacts on essential fish habitat. The Magnuson-Stevens Act also encourages NMFS to designate habitat areas of particular concern. These are specific habitat areas, a subset of the much larger area identified as essential fish habitat, that play a particularly important ecological role in the fish life cycle or that are especially sensitive, rare, or vulnerable. Designating habitat areas of particular concern allows the PFMC and NMFS to focus their attention on conservation priorities during review of proposals, affords those habitats extra management protection, and gives the fish species within these areas an extra buffer against adverse impacts.

Under the ESA, NMFS and USFWS are responsible for the conservation of threatened and endangered species, including fish, wildlife, and plants under their jurisdiction. The agencies are required, to the maximum extent prudent and determinable, to identify and designate critical habitat for threatened and endangered fish and wildlife species under their jurisdictions. Critical habitat is 1) specific areas within the geographical area occupied by the species at the time of listing if they contain physical or biological features essential to conservation, and those features may require special management considerations or protection; and 2) specific areas outside the geographical area occupied by the species if the agency determines that the area itself is essential for conservation. Under section 7 of the ESA, all federal agencies must ensure that any actions they authorize, fund, or carry out are not likely to jeopardize the continued existence of a listed species, or destroy or adversely modify its designated critical habitat. These complementary requirements apply only to federal agency actions, and the latter apply only to habitat that has been designated. A critical habitat designation does not set up a preserve or refuge; it applies only when federal funding, permits, or projects are involved.

3.3.3 Existing Conditions

3.3.3.2 Pelagic Environment

The term 'pelagic' is commonly used in reference to the upper water column of the open ocean that is not in association with the ocean bottom or bathymetric features. The oceanographic processes in the action area are generally large in scale, with ocean circulation driven by a major eastern boundary current system, the California Current System. Local conditions are energetic, dynamic, and affected by oceanographic processes operating across a spectrum of temporal and spatial scales. These physical processes and their pronounced effects on the area's biota are described in the following sections.

3.3.3.2.1 Physical Features and Processes

Large-scale Ocean Currents

The action area on the Washington coast is situated in an eastern boundary current system where the North Pacific Current divides into the northward flowing Alaska Current and the California Current System to the south (Hickey 1998; Gramling 2000). The California Current System is composed of the California Current, the California Undercurrent, the wintertime Davidson Current, and possibly a subsurface Washington Undercurrent. The relative strength of these currents and their influence on the temperature, salinity, flow, and productivity of the action area varies considerably over seasonal and interannual time scales (Hickey 1998; Hickey and Banas 2003; MacCall et al. 2005). The components of the California Current System are described

below, along with discussion of how they contribute to the dynamic physical environment of the action area.

The California Current extends up to 600 miles (966 km) offshore and ranges from the Pacific Northwest south to Baja California (Hickey 1979; Miller 1996; Hickey 1998; Burtenshaw et al. 2004). The California Current is a major force in shaping local ecosystems by affecting upwelling, downwelling, and biological production along the Pacific coast (Airamé et al. 2003). Despite being one of the most studied oceanographic systems in the Pacific Ocean, the mechanisms underlying the variability of this meandering current are still obscurely understood and inadequately sampled (Miller 1996). Flow of the California Current is strongest in the summer and early fall and weakest in the winter (Hickey 1998; Gramling 2000; Hickey and Banas 2003). The California Current is strongly affected by seasonal wind forcing (Thomas et al. 2003), and shifts in regional climate can have dramatic effects on its flow (e.g., during El Niño events, the flow of the California Current is unusually weak) (Hickey 1979; Gramling 2000). For further description of El Niño events, see El Niño Southern Oscillation Cycle below in this subsection.

The California Undercurrent is a permanent, relatively narrow (6- to 25-mile/9.6- to 40.2-km), deep subsurface feature that flows northward over the continental slope from Baja California to Vancouver Island (Reed and Halpern 1976; Hickey 1998; Neander 2001). The California Undercurrent transports warm, saline, low-oxygen, equatorial water to the northern Pacific, with strongest northward flows in the summer or early fall and minimum flows in the spring (Hickey 1998; Neander 2001; Hickey and Banas 2003). During El Niño years, when flow of the California Current is weakened, the California Undercurrent is unusually enhanced (Hickey 1979; Gramling 2000).

The Davidson Current is an inshore, seasonal, northward flowing feature that develops when the southward flowing California Current is weaker and situated further offshore. The Davidson Current is approximately 60 miles (97 km) wide, extends seaward of the continental slope, and transports warm, saline, low-oxygen, high-phosphate, equatorial water to the north (Gramling 2000; Hickey and Banas 2003). The Davidson Current develops along the Washington coast in September, is well established in January, and dissipates by May (Purdy 1990; Hickey and Banas 2003). The strongest flow of the current occurs during the winter months (Hickey and Banas 2003). There is speculation that the Davidson Current is a surface expression of the California Undercurrent (Hickey 1979).

There is some indication that a southward undercurrent, the Washington Undercurrent, occurs over the continental slope of Washington and Oregon in the winter (Werner and Hickey 1983; Purdy 1990). This undercurrent is located 1,000 to 1,600 feet (305 to 488 m) deep, deeper than the northward-flowing California Undercurrent (Hickey 1998; Hickey and Banas 2003).

Dynamic Processes and Variability

Seasonal Variability, Upwelling, and Downwelling

Seasonal variations in the oceanography of the action area occur in response to various forcing events, including solar heating and cooling, wind mixing, freshwater runoff, and coastal upwelling (Brueggeman et al. 1992). The seasonal pattern of the physical environment is typified by periods of intense coastal upwelling (April through September) and periods of relaxed winds (October through March) punctuated by strong winter storms (November to March).

Upwelling is a wind-driven, dynamic process that brings nutrient-rich deep water to the surface and transports nutrient-poor surface waters offshore (Mann and Lazier 1991). During spring and summer, northwesterly winds and the earth's rotation combine to push the surface waters offshore. This, in turn, results in the movement of deeper cold water upward into surface waters, introducing nitrate, phosphate, and silicate nutrients essential for phytoplankton production. Periods of wind relaxation lasting 2 to 6 days may alternate with upwelling-favorable conditions during the spring, contributing to dynamic and patchily distributed nutrient availability and productivity. The strongest upwelling in the action area occurs during July and August (Brueggeman et al. 1992; Airamé et al. 2003). Prolonged periods of wind relaxation may occur from late summer to early fall. The timing and intensity of regional upwelling varies from year to year (Huyer et al. 1979; Strub and James 1988; Bograd et al. 2009) and with changes in long-term climatic phenomena (El Niño Southern Oscillation Cycle and Pacific Decadal Oscillation in this section, below) (Huyer and Smith 1985; Barth and Smith 1997).

In October or November, there is a shift in wind direction that results in predominant winds that flow from the east/southeast (Norman et al. 2004), resulting in the onshore transport of surface waters and the conditions typical of fall and winter that favor downwelling (Hickey 1998). During periods of diminished upwelling or downwelling, the survivorship and reproductive success of planktivorous invertebrates and fishes decrease in response to reduced plankton abundance and productivity (Airamé et al. 2003; Bograd et al. 2009). Between late November and mid-March, low pressure systems from the Gulf of Alaska generate strong winter storms, southerly winds, and large waves in the Pacific Northwest (Strub and Batchelder 2002; Airamé et

al. 2003). These winter storms create intense vertical mixing, usually persist for only a few days, and are important sources of localized oceanographic disturbance.

Eddies and Fronts

During the spring, the large counterclockwise Juan de Fuca Eddy (or Tully Eddy) (Tully 1942) develops offshore of northern Washington at the mouth of the Strait of Juan de Fuca (Burger 2003; Hickey and Banas 2003). The eddy forms as a result of the interaction between effluent from the Strait of Juan de Fuca, southward wind-driven currents along the continental slope, and the bathymetry of the region (Hickey and Banas 2003). At its maximum, the eddy has a diameter of approximately 30 miles (48 km), and it is the dominant circulation pattern off northern Washington until its decline in the fall (Freeland and Denman 1982; Hickey and Banas 2003). The eddy upwells deep, cold, nutrient-rich water into surface waters, resulting in locally enhanced biological productivity (Freeland and Denman 1982; Thomson et al. 1989; Freeland 1992).

Ephemeral eddies and offshore filaments of variable duration (days, weeks, months, years) are also generated by meanders of the California Current, bathymetric features, and coastal upwelling events. Such ephemeral features are most common during summer and fall in the California Current System (Huyer et al. 1998; Barth et al. 2000; Strub and James 1988; Ressler et al. 2005). As with the Juan de Fuca Eddy, ephemeral counterclockwise eddies stimulate enhanced productivity by drawing cooler, nutrient-rich waters to the surface, while clockwise eddies are associated with warmer, nutrient-poor, and less productive conditions. Ephemeral eddy-like features are also generated by the Columbia River plume (see Columbia River Plume below in this section) (Yankovsky et al. 2001; Berdeal et al. 2002). Subsurface eddies are generally observed within and overlying submarine canyons off the Pacific coast (Hickey and Banas 2003), providing an effective mechanism for locally increased productivity and the suspension of sediment and organic detritus over these features (Hickey 1995).

Oceanic ‘fronts’ are zones of high water property gradients (e.g., gradients in temperature, salinity, and nutrients). Ephemeral fronts often exist at the interface between upwelled water and ambient coastal water, and the onset and relaxation of upwelling may result in the cross-shelf transport of planktonic organisms associated with these gradients. Persistent fronts tend to occur regularly at certain locations along the coast (e.g., capes and points) and may extend 60 miles (97 km) offshore (Short 1992). Ephemeral fronts generated off of Vancouver Island may extend southward off of the Washington coast near the action area (Freeland and Denman 1982).

Columbia River Plume

The Columbia River plume, through its influence on sea surface salinity, has a major effect on the coastal oceanography of the Pacific Northwest, including the action area. In general, salinity increases southward along the Pacific coast (Hickey and Banas 2003). However, the low-salinity plume of freshwater discharge from the Columbia River constantly changes direction, depth, and width in response to variation in discharge and fluctuations in local wind strength and direction (Hickey et al. 1998; Berdeal et al. 2002; Hickey and Banas 2003). In spring and summer, the plume moves southward, well offshore of the Oregon shelf (Hickey and Banas 2003) and has no influence on the coastal oceanography of the action area. During the winter, however, the plume flows northward and can generate local currents with magnitudes on the order of wind-driven currents in the near-surface layer (Hickey et al. 1998). In addition to seasonal variability, the structure and magnitude of the Columbia River plume has significant interannual and long-term variability (Hickey and Banas 2003). For example, in years of high snowmelt in the Pacific Northwest, fresh water generated from the plume can influence coastal oceanography for prolonged periods.

El Niño Southern Oscillation Cycle

El Niño Southern Oscillation events (including both El Niño and La Niña events) produce extreme interannual anomalies in global climate, atmospheric circulation, and oceanographic processes (Jacobs et al. 1994; Schwing et al. 1996). El Niño Southern Oscillation conditions typically last 6 to 18 months, although they can persist for longer periods (Barber and Chavez 1983; Lynn et al. 1998; Durazo et al. 2001; Schwing et al. 2002a; Schwing et al. 2002b). El Niño conditions occur when unusually high atmospheric pressure develops over the western tropical Pacific and Indian Oceans, and low sea level pressures develop in the southeastern Pacific (Trenberth 1997; Conlan and Service 2000). The trade winds consequently weaken in the central and west Pacific, reducing the normal east to west surface water transport. Upwelling along South America decreases, resulting in shoaling of the thermocline[1], increased sea surface temperatures, and diminished productivity across the mid to eastern Pacific (Donguy et al. 1982). Rainfall patterns also shift eastward across the Pacific, resulting in increased (sometimes extreme) rainfall across the southern United States and Peru (Conlan and Service 2000). La Niña is the opposite phase of El Niño in the El Niño Southern Oscillation Cycle. La Niña is characterized by strong

[1] A thermocline is the depth where water temperature changes relatively rapidly and separates less dense, warmer waters from denser, colder waters.

trade winds that push the warm surface waters back across to the western Pacific (Schwing et al. 2000). Under these conditions there is increased upwelling along the eastern Pacific coastline, the thermocline in the eastern Pacific becomes shallower, and there is increased upwelling and productivity.

Although the direct effects of El Niño Southern Oscillation events are observed in the equatorial latitudes, significant correlations exist between the climate of the Pacific Northwest and El Niño/La Niña events (e.g., Pulwarty and Redmond 1997; Cayan et al. 1999). In the Pacific Northwest, El Niño events are characterized by increases in ocean temperature and elevated sea level (4 to 12 inches/10.2 to 30.5 cm), enhanced onshore and northward flow, and reduced coastal upwelling (Crawford et al. 1999; Smith et al. 1999; Freeland 2000; Airamé et al. 2003). Historically, the region was impacted by strong El Niño events in 1940, 1958, 1983, 1992, 1997 to 1998, and 2004 to early 2005 (Hayward 2000; Lyon and Barnston 2005). The 1997 to 1998 El Niño was one of the largest ocean perturbations in the historical record, inducing a 4 to 5 °Fahrenheit (F) (2.2 to 2.8 °Celsius [C]) warming of sea surface temperatures over the historical average and profoundly affected the productivity and marine ecology of the region (Castro et al. 2002; Airamé et al. 2003; Childers et al. 2005; Zamon and Welch 2005). This El Niño was immediately followed by an equally strong, cold La Niña event in 1999. While the effects of such events can be conspicuous in the water column, Paine (1986) noted that they may be masked or diluted for the benthic community. For the ENP gray whale, Subsection 3.4.3.3, Distribution and Habitat Use, discusses the effect of oceanic climatic cycles, including El Niño/La Niña events, on gray whale distribution and habitat use; and Subsection 3.4.3.4.2, Stranding Data, discusses the potential relationship between the 1997 and 1998 El Niño events and the ENP gray whale unusual mortality event.

Marine Heatwaves

Marine heatwaves (MHWs) are extreme warm sea surface temperature (SST) events that persist for days to months and can extend up to thousands of square kilometers (Scannell et al. 2016; Frölicher et al. 2018). Hobday et al. (2016) outlined three specific characteristics to define MHWs: (1) an area of anomalously warm water compared to a 30-year baseline for that area; (2) prolonged duration lasting for at least five days; and (3) discrete in that there is a defined start and end date that may include gaps of less or no warming. The SST generally exceeds the local 90th percentile for the duration of the five-day minimum period. MHWs are believed to be caused by unusual weather patterns that either cause the ocean to absorb more heat, which warms the surface layer, or prevent heat from escaping from the ocean (NOAA Research 2019). Anomalous

barometric pressure at sea level is often linked to MHWs because it suppresses heat loss from the ocean to the atmosphere (Bond et al. 2015; Leising et al. 2015; Cavole et al. 2016).

The frequency of MHWs has increased globally since 1985 as the upper ocean temperatures have warmed around the world (Oliver et al. 2018). It is very likely that 84-90 percent of MHWs have occurred between 2006 and 2015, caused by increased temperatures due to anthropogenic climate change. Future MHWs are projected to increase in frequency, duration, spatial extent, and intensity (maximum temperature) (IPCC 2019). The largest changes in MHW occurrences are projected for the tropical Pacific and the Arctic Ocean (Frölicher et al. 2018). There have been six notable MHWs in recent history: in the northern Mediterranean Sea in 2003; off the Western Australian coast in 2011; in the northwest Atlantic in 2012; in the northeast Pacific from 2013 to 2015; off of southeastern Australia in 2015 and 2016; and through northern Australia in 2016 (Oliver et al. 2018). The MHW in the northeastern Pacific from 2013 to 2015, referred to as the "Blob," was the largest recorded MHW (Frölicher & Laufkötter 2018). During that event, the West Coast of North America experienced increased marine layer stratification, decreased nutrient fluxes (due to decreases in upwelling), and the deepening of the nutricline (Cavole et al. 2016). Offshore ocean temperatures reached as high as 4 degrees Celsius above the climatological mean (Leising et al. 2015). A Blob-like event developed in the northeastern Pacific Ocean again in the summer and fall of 2019. It was the second largest MHW event in terms of area and was one of the top five largest MHWs recorded within the last 40 years in the region (Northwest Fisheries Science Center 2019).

The long-term impacts of MHWs remain uncertain. Short-term impacts have been severe in some regions. Recent MHWs have resulted in kelp forest loss, coral bleaching, decreases in surface chlorophyll, mass mortality of marine invertebrates, greater toxicity of harmful algal blooms (HABs), rapid shifts in species ranges, fisheries closures, increases in seabird and sea lion disability and mortality, and increases in whale entanglements (Cavole et al. 2016; McCabe et al. 2016; Oliver et al. 2018; Santora et al. 2020). Marine species appear more susceptible to acute environmental extremes than to slower changes in ocean temperature (Oliver et al. 2018). Many species have shifted their distributions north during the warming events in the North Pacific Ocean (Cavole et al. 2016), similar to range shifts witnessed during El Niño events (Sanford et al. 2019). Some species' ranges return to their normal extent once the warming has stopped; other species have developed relict populations that slowly disappear or sink populations that can persist indefinitely (Sanford et al. 2019).

The Blob resulted in lower primary productivity from weak upwelling and extremely low levels of ocean mixing and a shift in warm water copepod abundance in the northern California Current (Leising et al. 2015; Di Lorenzo & Mantua 2016). The decrease in productivity led to a decrease in the amount of krill near the coast, which resulted in prey switching by large cetaceans such as humpback whales and large die-offs of some seabirds (Cavole et al. 2016; Harvey et al. 2020). HABs in Washington, Oregon, and California resulted in increased levels of domoic acid that delayed and closed fisheries and led to the death of many seabirds (Cavole et al. 2016; Di Lorenzo & Mantua 2016). However, some of these impacts appear to be temporary. For example, northern copepod biomass has increased steadily since 2016, as has the mean body length of krill (Harvey et al. 2020). Another study found that ecological communities returned back to their usual state following disturbance after the Blob (Hunsicker et al. 2022). Although reported entanglements of humpbacks were higher in 2019 than pre-2014 levels, they were lower than the number of reports received each year from 2015-2018 (Harvey et al. 2020). In addition, while it is unclear what, if any, impact the Blob may have had on the ENP gray whale stock, that stock continued to grow steadily through that event, with a 22 percent increase in abundance estimates in 2014/2015 and 2015/2016 since the 2010/2011 estimates (Durban et al. 2017). Still, the California Current Ecosystem has experienced exceptional ocean warming due to El Niño events and MHWs since 2013, and the impacts of this warming will continue to warrant investigation (Harvey et al. 2020).

Pacific Decadal Oscillation

The Pacific Decadal Oscillation is a long-term (approximately every 20 to 30 years) climatic pattern correlated with alternate regimes of sea surface temperature, surface winds, and sea level atmospheric pressure (Mantua 2002; Mantua and Hare 2002). The Pacific Decadal Oscillation is often described as a long-lived, El-Niño-like pattern of Pacific climate variability with both warm and cool phases (Mantua 2002; Mantua and Hare 2002; Airamé et al. 2003; Minobe et al. 2004). There are, however, noteworthy distinctions between the Pacific Decadal Oscillation and El Niño Southern Oscillation-induced events: (1) Pacific Decadal Oscillation regimes can persist for 20 to 30 years, in contrast to the comparatively shorter duration of El Niño Southern Oscillation events (typically up to 18 months) (Minobe 1997; Minobe 1999; Hare and Mantua 2000; Mantua and Hare 2002); (2) the ecosystem effects of the Pacific Decadal Oscillation are more pronounced in temperate latitudes (Hare and Mantua 2000); and (3) the mechanisms controlling the Pacific Decadal Oscillation are unknown, while those underlying El Niño Southern Oscillation variability have been well resolved (Mantua and Hare 2002). During warm Pacific Decadal Oscillation

regimes, the western and central North Pacific Ocean typically exhibit cold sea surface temperature anomalies, while the eastern Pacific (including the action area) exhibits above-average temperatures and reduced productivity. The opposite conditions exist during cool Pacific Decadal Oscillation regimes. The Pacific Decadal Oscillation has been correlated with markedly different regimes of Columbia River discharge (Mantua et al. 1997), ocean productivity, zooplankton species composition, and forage fish and salmonid recruitment in the Pacific Northwest (e.g., Hare et al. 1999; Tanasichuk 1999; Botsford 2001; Mueter et al. 2002; Gustafson et al. 2006). The Pacific Decadal Oscillation regime shifts are abrupt, with observed shifts occurring in 1925, 1947, and 1977 (Hare 1996; Minobe 1997). The most recent shift, from a warm to a cool phase, occurred in 1998 (Airamé et al. 2003; Peterson and Schwing 2003; Childers et al. 2005; Gómez-Gutiérrez et al. 2005). For the ENP gray whale, Subsection 3.4.3.3, Distribution and Habitat Use, discusses the effect of oceanic climatic cycles, including the Pacific Decadal Oscillation, on gray whale distribution and habitat.

3.3.3.2.2 Biological Resources

Phytoplankton

The biological productivity and composition of the action area is best characterized as diverse, variable, and patchily distributed owing to the dynamic physical processes described above which vary across a spectrum of temporal and spatial scales. Phytoplankton (freely floating photosynthetic organisms) are responsible for the bulk of the primary production in the ocean (the conversion of inorganic carbon to organic matter) and form the basis of the pelagic food web. The distribution and concentration of phytoplankton are affected by ocean currents, vertical mixing, and the rate of photosynthesis. The intensity and quality of light, the availability of nutrients, and seawater temperature all influence rates of photosynthesis (Valiela 1995). The Pacific Northwest coast supports high phytoplankton production, stimulated by the upwelling of nutrient-rich waters and retention of phytoplankton by local oceanographic currents and bathymetric features (Sutor et al. 2005). In general, the Washington coast experiences two seasonal peaks in phytoplankton production; the first occurs from February to April, and the second occurs in October. There is, however, considerable spatial and temporal variability in the production and distribution of phytoplankton caused by the physical oceanographic processes described above. For example, during an El Niño event, less upwelling occurs along the Pacific Northwest coast, fewer nutrients are available for phytoplankton growth, and phytoplankton concentration may decrease by as much as 70 percent compared to an average year (Wheeler and Hill 1999; Thomas and Strub 2001).

In addition to controlling the distribution and concentration of phytoplankton, physical oceanographic processes also affect the species and size composition of phytoplankton in the water column. For example, the onset and relaxation of upwelling events result in dramatic shifts in the phytoplankton community within the California Current System. Newly upwelled water along the shelf is composed chiefly of high concentrations of large, chain-forming diatoms. Following upwelling events, the phytoplankton community is predominantly composed of reduced concentrations of small phytoplankton species (less than 5 microns in size) (Sherr et al. 2005) better adapted to survival in low-nutrient conditions. Similarly, during low productivity conditions induced by El Niño events, 80 to 90 percent of the phytoplankton community along Pacific Northwest shelf waters consists of these smaller phytoplankton species (Corwith and Wheeler 2002; Sherr et al. 2005).

Zooplankton

Zooplankton are a taxonomically diverse group of organisms that consume phytoplankton (as well as other zooplankton). Juvenile crabs (megalopae), copepods, amphipods, euphausiids, and chaetognaths tend to dominate the near-surface zooplankton community (Peterson 1997; Reese et al. 2005; Swartzman et al. 2005). The distribution of zooplankton along the coastline can be described as spatially and temporally patchy, reflecting the variable concentration and distribution of phytoplankton prey, as well as the underlying dynamic physical environment (Reese et al. 2005; Ressler et al. 2005). The highest zooplankton concentrations typically are found within 90 miles (145 km) of the coastline (Swartzman and Hickey 2003; Ressler et al. 2005; Swartzman et al. 2005) in the upper 66 feet (20 m) of the water column over the inner and mid shelf (Peterson and Miller 1975; Peterson and Miller 1977). Zooplankton densities along the Pacific Northwest are highly seasonal, with summer densities ten times greater than those observed during the winter months (Burger 2003; Reese et al. 2005). Copepods form the largest fraction of the zooplankton biomass. Although smaller copepods are numerically dominant (e.g., *Acartia* spp.), larger copepods make up most of the zooplankton biomass (e.g., *Calanus* spp.) (Strickland 1983) and tend to feed on the diatoms that dominate under upwelling conditions. Euphausiids, amphipods, and mysids are also important components of the zooplankton assemblage (Strickland 1983). Ephemeral, seasonal, interannual, and interdecadal physical oceanographic processes (described above) largely control the abundance, distribution, and species composition of zooplankton in the region (e.g., Batchelder et al. 2002; Botsford 2001; Peterson 1999; Peterson and Miller 1977; Peterson and Keister 2003; Tanasichuk 1999; Bograd et al. 2009).

Fish and Invertebrates

The productivity of the action area is strongly affected by the California Current System and the dynamic physical oceanographic processes that induce variability within the California Current System, as noted in Subsection 3.3.3.1.1, Physical Features and Processes, Large-scale Ocean Currents. The high productivity of the region produces a diverse plankton community that, in turn, supports a large assemblage of pelagic marine fish and invertebrates dependent upon this spatially and temporally patchy planktonic food supply (e.g., diatoms, dinoflagellates, copepods, euphausiids, and other organisms). Marine fish and invertebrate species associated with the pelagic environment include coastal pelagics, salmonids, midwater groundfish, and highly migratory species (Table 3-1). Various physical features within the action area such as ocean currents, upwelling, the Columbia River plume, fronts, and eddy features influence the distribution and abundance of pelagic prey species, as well as that of their fish and invertebrate predators (Doyle 1992; Dower and Perry 2001; Nasby-Lucas et al. 2002; Williams and Ralston 2002; Bosley et al. 2004; Emmett et al. 2004; Emmett et al. 2006). The distribution and abundance of pelagic fish and invertebrate species also are profoundly affected by interannual and interdecadal climatic variations such as El Niño/La Niña or the Pacific Decadal Oscillation (Hickey 1993). For example, dramatic changes in species assemblages were observed during extreme El Niño/La Niña years (1998 to 2002) off northern Washington State to central Oregon. The pelagic community shifted from one dominated by southern species (mackerels and hake) to one dominated by northern species (squid, smelts, and salmon), with the small pelagic species (sardines, herring, and anchovy) showing no consistent trends in abundance over this time (Brodeur et al. 2005).

Coastal Pelagic Species

The coastal pelagic species in the action area include four commercially valuable finfish species (Pacific sardine, *Sardinops sagax*; Pacific [chub] mackerel, *Scomber japonicus*; northern anchovy, *Engraulis mordax mordax*; and jack mackerel, *Trachurus symmetricus*) and market squid (*Loligo opalescens*) (NOAA 1993; PFMC 2022a) (Table 3-1). The distribution of coastal pelagic species typically depends on water temperature, but can vary both annually and seasonally (PFMC 2022a). For many of these species, occupancy zones may vary by life-history stage.

Table 3-1. Associations and times of occurrence for common pelagic and benthic species potentially present in the action area.

Fish	Typical Habitat	Time of Occurrence
Coastal Pelagic Species		
Sardine/anchovy/herring	Pelagic (open water) schooling fish	Year-round
Mackerel	Pelagic, schooling fish	Spring-summer
Squid	Pelagic, shelf zone	Spring-summer
Salmon		
Pacific salmon and steelhead	Pelagic, nearshore, upwelling areas	Year-round
Sea-run bull and cutthroat trout	Pelagic, nearshore, upwelling areas	Fall through winter (returning adults); spring (juvenile outmigrants)
Highly Migratory Species		
Tuna	Pelagic, shelf and slope	Year-round
Shark	Pelagic, nearshore, upwelling areas	Year-round
Groundfish		
Rockfish	Demersal (on or near the bottom), nearshore, shelf, and slope rocky areas	Year-round
Thornyhead	Demersal, shelf or slope, soft-bottom areas	Year-round
Flatfish	Demersal, nearshore/shelf, and slope sandy, muddy, or gravelly bottoms	Year-round
Gadid	Pelagic/semipelagic, nearshore, and shelf in large inlets	Year-round
Shark	Pelagic, nearshore and shelf	Year-round
Skate	Demersal, shelf, mud or sand substrate	Year-round
Lingcod and cabezon	Demersal, nearshore, rocky, or steep slopes	Year-round
Sablefish	Demersal, shelf slope, sand, mud, or clay substrate	Year-round
Green sturgeon	Demersal, shelf slope, sand, mud, or clay substrate	Summer
Other Demersal Species		
Halibut	Demersal, shelf, sand, and gravel substrate	Year-round
Crustaceans: mysids, euphausiids, amphipods	Nearshore, sand/mud substrate	Year-round
Crab	Nearshore, sand/mud substrate	Year-round

The PFMC and NMFS identified essential fish habitat for coastal pelagic species based on the temperature range where the fish occur and on the geographic area where they are present at any particular life stage. This range varies widely according to ocean temperature. Identifying essential fish habitat for coastal pelagic species is also based on where these species have been observed in the past and where they may occur in the future.

The east-west boundary of essential fish habitat for coastal pelagic species includes all marine and estuary waters from the coasts of California, Oregon, and Washington to the limits of the EEZ and above the thermocline (PFMC 2021). Surface temperatures above the thermocline exhibit considerable variability, ranging from 50 to 79 °F (10 to 26 °C). The northern essential fish habitat boundary is defined as the position of the 50° F isotherm, which varies seasonally and annually. The 50 °F (10 °C) isotherm is a rough estimate of the lowest temperature where coastal pelagic finfish managed by PFMC are found; thus, it represents their northern boundary. In years with cold winter sea surface temperatures, the 50 °F (10 °C) isotherm during February is around 43 degrees north latitude in the offshore zone and slightly farther south along the coast. In August, this northern boundary moves up to Canada or Alaska (PFMC and NMFS 2006). Therefore, the northern extent of essential fish habitat for coastal pelagic species likely occurs south of the action area in winter. During spring and summer months, with the northward migration of the 50 °F (10 °C) isotherm, essential fish habitat likely occurs within the action area.

Salmonid Species

All Pacific salmonid species exhibit varying forms of anadromy (they spend their early life stages in fresh water, migrate to the ocean to grow and mature, and return to fresh water as adults to reproduce). For further information on the life history and behavioral ecology of Pacific salmonid species, see Groot and Margolis (1991) and Emmett et al. (1991). Twenty-eight population groups of West Coast salmon and steelhead (*Oncorhynchus* spp.) are currently listed as threatened (23) or endangered (5) under the ESA. Threatened bull trout (*Salvelinus confluentus*) populations occur in major coastal rivers of Washington (64 FR 58913, November 1, 1999). Although limited data exist regarding the distribution of bull trout in marine waters, they are known to migrate between these rivers and are expected to occur occasionally in the action area (USFWS 2004). Although some of the ESA-listed salmonids noted above might occur in the action area, there is no designated critical habitat for these salmonids within the action area, except for the freshwater habitat areas used by threatened Ozette Lake sockeye salmon. The depressed production of many West Coast salmonid stocks, particularly the ESA-listed species, is due to a combination of factors, including freshwater habitat degradation and unfavorable ocean

conditions during the 1990s. The population sizes of some of these salmonid species have increased in recent years, presumably in part because of improved ocean survival conditions (Ford 2011; PFMC 2022b). As noted above, run sizes of salmonid species over decadal time scales appear to be strongly affected by the Pacific Decadal Oscillation ocean climate cycle (Subsection 3.3.3.1.1, Physical Features and Processes, Dynamic Processes and Variability, Pacific Decadal Oscillation). Salmonid species are also influenced by El Niño events, with the effect depending on the preferred water depth of the given species. Salmon that prefer more shallow habitats, such as coho salmon, are more likely to be affected by El Niño than other salmon species, such as Chinook salmon (PFMC 2022c).

The PFMC and NMFS identified essential fish habitat for salmon in estuaries and marine areas extending from the shoreline to the 200-mile (322 km) limit of the EEZ and beyond. In fresh water, salmon essential fish habitat includes all lakes, streams, ponds, rivers, wetlands, and other bodies of water that have been historically accessible to salmon (PFMC and NMFS 2006). The PFMC may use gear restrictions, time and area closures, and harvest limits to reduce negative impacts on salmon populations and essential fish habitat. Salmon essential fish habitat occurs throughout the year in the action area.

Highly Migratory Species

Highly migratory species include tuna, billfish, and sharks. These species exhibit a wide-ranging distribution throughout the Pacific Ocean and are not typically associated with specific substrata or benthic habitats (e.g., kelp forests or rocky substrata). Rather, their distribution often reflects large-scale oceanographic features with preferred levels of physical characteristics (for example, temperature, salinity, and oxygen), or concentrations of preferred prey (PFMC 2022d; see also PFMC (2022e) for a description of essential fish habitat by species).

For a general description of gray whale feeding on pelagic prey, see Subsection 3.4.3.1.3, Feeding Ecology and Role in the Marine Ecosystem. For a description of variable and dynamic gray whale habitat use and distribution in the action area related to pelagic prey distribution and climatic and ocean condition variability, see Subsection 3.4.3.3.1, ENP Seasonal Distribution, Migration, and Movements.

3.3.3.3 Benthic Environment

3.3.3.3.1 Physical Features and Processes

Substrata

Nearshore Habitats

As with the pelagic environment, nearshore benthic habitats are dynamic environments subject to energetic disturbances from climatic, oceanographic, and terrestrial processes. Nearshore habitat characteristics and species composition are strongly influenced by the dominant forms of marine algae, tidal range, depth, and type of substrate (Proctor et al. 1980). The nearshore habitats in the action area are composed of rocky shores, sandy beaches, and gravel beaches (Department of the Navy 2006). These habitats can be divided into several vertical zones: the splash zone, the upper intertidal zone (submerged for a short time and exposed to the widest range of temperatures), the mid-littoral zone (alternately submerged and exposed for moderate periods of time), the swash zone (submerged for approximately 12 hours per day), the low intertidal zone (exposed for brief periods of time during the lowest tides), and the subtidal zone (substrata below the lowest tides that are always submerged). These vertical zones reflect the intensity of the physical forces affecting nearshore habitats and structure the ecosystems that inhabit them.

Coastal Benthos

The continental shelf off the action area varies from 15 to 40 miles (24 to 64 km) wide, including habitats of hard and soft substrata. The most common seafloor habitat, particularly north of La Push, consists of mixed hard and soft substrates (e.g., coarse sand, gravel); hard-bottom habitats are the least common component of seafloor substrate (N. Wright, OCNMS, pers. comm., June 12, 2012). The Department of the Navy (2006) estimated that, beyond the depths of kelp beds (more than 100 feet/30 m), approximately 3 percent of the sea floor consists of hard-bottom substrata. Hard-bottom habitats may be composed of bedrock, boulders, cobble, or gravel.

The Columbia River is a major source of sediment for soft-bottom habitats along the Pacific coastline. The sediment is initially deposited near the mouth of the Columbia River. As winter storms pass through the Pacific Northwest, much of this sediment is transported northward along the coast, resulting in a 30-foot-thick (9-meter-thick) deposit of silt overlying the Washington continental shelf (Hickey and Banas 2003). Offshore soft-bottom habitats are composed primarily of silt and mud with sandy areas occurring closer to the coastline.

Submarine Canyons

The otherwise smooth bathymetry along the action area is broken by two submarine canyons, the Juan de Fuca and Quinault canyons, running perpendicular to the shore (Strickland and Chasan 1989). These habitats are dynamic, highly productive, and complex ecosystems. Submarine canyons facilitate locally increased upwelling, high nutrient availability, and vigorous productivity (Freeland and Denman 1982; Hickey 1995). Submarine canyons are also sites of

accumulation for organic debris from drift macroalgae, surfgrass, and plankton detritus produced in surface waters. The complex habitat structure of submarine canyons (such as vertical cliffs, ledges, talus, cobble and boulder fields, and soft sediments) also provides cover for numerous fish and invertebrate species.

Dynamic Processes and Variability

Nearshore community structure and species composition in rocky tidal and beach habitats are principally determined by the frequency and magnitude of physical disturbances (Sebens 1987), intense intra- and inter-specific competition and predation (Connell 1978; Paine 1969; Robles and Desharnias 2002), and highly variable recruitment dynamics (Gaines and Roughgarden 1985; Menge and Sutherland 1987; Roughgarden et al. 1988). These nearshore habitats and the organisms that inhabit them are subjected to nearly constant and intense physical agitation and disturbance (Proctor et al. 1980; Airamé et al. 2003) from wind, waves, tides, temperature, desiccation, sediments, and sand scouring. Despite some protection from offshore islands, submarine ridges, projecting headlands, and large offshore kelp beds, the coast of the action area is subject to strong wave action even in calm weather.

Soft substrata habitats of the coastal benthos are structured by depth gradients in temperature, disturbance by storms and wave action, and movement and accumulation of sediments (Maragos 2000). Submarine canyons that indent the Washington coastal shelf, such as the Juan de Fuca and Quinault canyons in the action area, facilitate locally increased upwelling and nutrient availability in nearshore areas (Freeland and Denman 1982; Hickey 1995). Turbidity currents associated with submarine canyons represent episodic disturbances that serve as major conduits for sediment transport to the deep sea. These turbidity currents erode canyon walls, transport loose sediments and detrital material, and significantly structure infaunal communities associated with submarine canyons (Vetter and Dayton 1998; Vetter and Dayton 1999).

As in the pelagic environment, benthic and nearshore environments may also be affected by short-term MHWs that are becoming more frequent in the 21st century (Frolicher et al. 2018; Hobday et al. 2016; Oliver et al. 2018).

The Salish Sea

The semi-enclosed inland waters of Washington State and British Columbia are collectively known as the Salish Sea. This area encompasses the Strait of Juan de Fuca, the Strait of Georgia, and Puget Sound. These three areas were seen as distinct water bodies until 2010 when they were unified under the Salish Sea name to honor the region's first inhabitants, the Coast Salish people

(Gaydos et al. 2009; Tucker and Rose-Redwood 2015; Western Washington University 2020). The Salish Sea is bordered by 7,470 km (4,642 mi) of coastline, has a sea surface area of 16,925 km^2 (6,535 mi^2), and contains the largest estuary by water volume in the United States (Puget Sound Partnership 2019; SeaDoc Society 2020). Researchers estimate that 37 mammal species (including gray whales, see subsection 3.2.1.2), 172 bird species, 253 fish species, and over 3,000 invertebrate species utilize the Salish Sea habitat to some degree (Gaydos and Brown 2011; Gaydos and Pearson 2011).

The environment of the Salish Sea is characterized by strong seasonality and spatial gradients in dissolved oxygen, temperature, salinity, and primary productivity (Masson and Cummins 2007; Grundle et al. 2009; Johannessen and Macdonald 2009). Snowmelt and rain in the Cascade and Olympic mountain ranges drain into the Salish Sea, delivering minerals and nutrients to the marine zone (EPA 2019). In addition to the nutrients delivered from freshwater input, coastal upwelling also plays an important role in primary productivity in the Salish Sea, as ocean-derived nutrients entering the Strait of Juan de Fuca spur spring phytoplankton blooms and fuel biogeochemical cycles (Mackas and Harrison 1997; Khangaonkar et al. 2012; Allen and Wolfe 2013). On the sea floor, the primary driver of benthic productivity in the Salish Sea is temperature, followed by the quality of organic matter on the benthic substrate following phytoplankton blooms (Belley et al. 2016). Like the adjacent northern California Current Ecosystem, dynamic physical processes affect the ecosystem structure, ecological interactions, and species' recruitment mechanisms in the Salish Sea, especially in that portion overlapping with the action area.

3.3.3.3.2 Biological Resources

Marine Algae, Marine Plants, and Associated Biota

Surfgrass (*Phyllospadix* spp., and associated macroalgae) and kelp (bull kelp *Nereocystis luetkeana*, giant kelp *Macrocystis pyrifera*, and other brown algae) communities are associated with rocky nearshore habitats. Surfgrass (*Phyllospadix* spp.) is an aquatic plant species present in rocky subtidal and intertidal habitats with high wave exposure. Surfgrass occurs from the intertidal zone to 23 feet (7 m) deep (Ramírez-García et al. 2002), exhibits very high rates of production (Proctor et al. 1980), and hosts a diverse community of invertebrates and fishes. Kelp communities are found 6 to 200 feet (2 to 61 m) deep (Rodriguez et al. 2001) and can persist in areas subject to severe wave action and tidal currents. The overlying canopies, understory, turf, and coralline algae layers of kelp forests provide essential refuge, forage, and nursery habitats for associated algal, invertebrate, and fish communities (Proctor et al. 1980; Rodriguez et al. 2001).

Kelp forests also provide an important food resource for inhabitants of soft and rocky benthic habitats, submarine canyons, deep channel basins, sandy and gravel beaches, rocky shores, and coastal lagoons (Airamé et al. 2003). Several marine mammal species, including sea otters and gray whales, forage and find refuge from predators in kelp forests (Cummings and Thompson 1971; Deysher et al. 2002; Nerini 1984). Kelp forests exhibit extremely high rates of primary production, growing up to 4 inches (10.2 cm) per day. Temperature, light, sedimentation, substrate, relief, wave exposure, nutrients, salinity, and biological factors (i.e., grazing, competition with other species) determine the distribution and abundance of kelp (Graham 1997). The highest densities are found on moderately low relief rocky substrata with moderate to low sand coverage (Deysher et al. 2002), while areas with very low relief and abundant sand are less favorable to persistent stands of kelp (Foster and Schiel 1985; Graham 1997). In addition to the primary habitat that kelp forests provide, they also provide secondary habitat for juvenile fishes, invertebrates, and seabirds in the form of drifting rafts of detached kelp.

Infaunal, Benthic, and Epibenthic Organisms

Rocky benthic subtidal habitats support extensive communities of benthic marine algae and invertebrates, as well as demersal invertebrates (e.g., mysids and cumaceans) living in close association with the sea floor (refer to Marine Algae, Marine Plants, and Associated Biota above). Sessile benthic invertebrates in these habitats are subject to less severe physical agitation and disturbance than in rocky intertidal habitats. As with intertidal communities, however, intense intra- and inter-specific competition and predation, along with highly variable recruitment dynamics, are principal forces in structuring the abundance, composition, and variability of these communities.

Soft-bottom subtidal habitats also support a rich diversity of infaunal invertebrates, including amphipod crustaceans, echinoderms, and polychaete worms, as well as highly motile epibenthic invertebrate species (such as Dungeness crab). Benthic infauna are organisms that live in the sediments by attaching to the soft substratum, dwelling in tubes, or burrowing through the sediments. Infaunal communities are often used as baselines for ecological assessments because they tend to exhibit more stable species composition and population dynamics than more mobile epifaunal assemblages such as crabs or bottom fish. This apparent stability is, however, subjected to considerable physical disturbance and variability and should not be interpreted to reflect a static environment. Soft-bottom benthic habitats along the Washington coast, including the action area, are productive biological environments influenced by a variety of complex physical processes (Braun 2005). The major short-term processes that affect infaunal communities include

predation (e.g., by gray whales; Feyrer 2010), as well as tidal-, wind-, and wave-induced turbulence; currents; sedimentation from the Columbia River plume and local rivers; storms; and variability in food availability associated with upwelling and plankton blooms (Braun 2005). The infauna that inhabit this environment are adapted to these high-energy environments with high sediment deposition, erosion, and sediment transport. Large storms with large waves, large freshwater outputs from the Columbia River and other rivers, and semi-diurnal tides act to suspend sediments and organic particulates. The organisms that inhabit these constantly shifting substrata tend to be highly motile rapid burrowers, rapid tube builders, or rapid colonizers with regular recruitment. Seasonal and interannual variability in the species composition and abundance of infaunal communities off the Washington coast is considerable, particularly at inshore locations influenced by sediment movement resulting from winter storms and river outfalls (Richardson et al. 1977). In summary, benthic soft-bottom habitats are subject to frequent high-intensity disturbances and are inhabited by infaunal communities of opportunistic colonizers exhibiting strong seasonal variability and spatial patchiness (Richardson et al. 1977; Oliver et al. 1980; Hancock 1997).

For a general description of gray whale feeding on benthic prey, refer to Subsection 3.4.3.1.4, Feeding Ecology and Role in the Marine Ecosystem. For a description of gray whale benthic feeding in the northern portion of the summer range, refer to Subsection 3.4.3.3.1, Summer Range Distribution and Habitat Use, Northern Portion of the Summer Range. For a description of gray whale benthic feeding occurring in the action area, refer to Subsection 3.4.3.3.1, ENP Seasonal Distribution, Migration and Movements.

Groundfish

Benthic habitats along the continental shelf support a large biomass of demersal (bottom-dwelling) groundfishes (Dark and Wilkins 1994). Adult groundfish species (e.g., rockfish, *Sebastes spp*.; sablefish, *Anoplopoma fimbria*; Pacific hake/whiting, *Merluccius productus;* spotted ratfish, *Hydrolagus colliei*; and spiny dogfish, *Squalus suckleyi*) can be associated with hard substrata of offshore reefs, banks, and submarine canyons, as well as soft or mixed substrates. As with pelagic species, physical oceanographic processes such as currents, upwelling, the Columbia River plume, fronts, and eddy features influence the distribution and abundance of groundfish species (Doyle 1992; Dower and Perry 2001; Nasby-Lucas et al. 2002; Williams and Ralston 2002; Bosley et al. 2004; Emmett et al. 2004; Emmett et al. 2006). The groundfish community in the Pacific Northwest also exhibits a strong depth gradient in species composition and diversity (Tolimieri and Levin 2006). Many groundfish species produce pelagic larval and

juvenile life stages, which generally float or swim near the sea surface and may be associated with floating debris such as kelp rafts. Pelagic larval and juvenile life stages are widely dispersed by storms, upwelling and ocean currents, and have limited associations with specific nearshore or benthic habitats (NOAA 1993). Older life stages, however, exhibit stronger habitat associations based on specific zones, depths, or substrate characteristics. Other groundfish species may exhibit seasonal migrations, resulting in an annual variation in habitat preferences (NMFS 2005c). The distribution, abundance, and recruitment of groundfish species is also strongly affected by climatic/oceanographic variability such as El Niño events. During periods of El Niño, there is an overall northward shift of tropical and temperate species (Cross 1987; Cross and Allen 1993). Rockfish respond in a range of ways to climate variability: in some major El Niño events, rockfish experienced a decline in overall biomass as a result of recruitment failure and reduced growth of adults due to poor ocean conditions in the region (Lenarz et al. 1995; Moser et al. 2000). In contrast, many rockfish experienced surprisingly strong recruitment in the midst of the 2015 MHW, due in part to local upwelling that produced good reproductive conditions for adult females (Schroeder et al. 2019).

With respect to conservation status, one West Coast groundfish species, yelloweye rockfish (*Sebastes ruberrimus*) occurring in the action area is designated as rebuilding under the Magnuson-Stevens Act (PFMC 2022f) (an overfished species is defined as a population below 25 percent of its natural [unfished] population size, a rebuilding species is defined as a population below 40 percent of its natural [unfished] population size). The PFMC and NMFS have established the Yelloweye Rockfish Conservation Area in the action area to limit the incidental catch of this rebuilding species.

Two non-salmonid, ESA-listed species of fish occur in the action area—green sturgeon and eulachon. The Southern distinct population segment of North American green sturgeon (*Acipenser medirostris*), which spawns in the Sacramento River (California), was listed as threatened on April 7, 2006 (71 FR 17757). Its critical habitat includes the entire action area out to a depth of 60 fathoms (74 FR 52300, October 9, 2009). The Southern distinct population segment of Pacific eulachon was listed on March 18, 2010 (75 FR 13012) and also occurs in the action area. None of its critical habitat occurs within the action area.

Essential fish habitat has been designated by the PFMC and NMFS for groundfish in the action area. A comprehensive description of essential fish habitat off the coast of Washington is available in the Final Groundfish Essential Fish Habitat EIS (NMFS 2005c), and was recently updated in 2019 (PFMC 2019). In addition to designating essential fish habitat for groundfish,

NMFS has also identified habitat areas of particular concern (HAPCs) for groundfish. HAPCs include seagrass, canopy kelp, rocky reef, and estuaries along the Pacific coast, including the action area (PFMC 2022f).

3.4 Gray Whales

3.4.1 Introduction

The Makah Tribe included in its request "certain management measures . . . designed to minimize impacts to those whales that exhibit inter-annual site fidelity to the Pacific coast south of Alaska."[2] While a Makah whale hunt (as proposed by the Tribe) would target migrating ENP gray whales, it might also kill gray whales from the Pacific Coast Feeding Group (PCFG), and there is a chance that Western North Pacific (WNP) gray whales might be killed, subjected to harpoon attempts, or approached. More detailed information about ENP, WNP, and PCFG whales is contained in Subsection 3.4.3, Existing Conditions. The status, population structure, distribution, and habitat use of the gray whale are relevant when analyzing the effects of any hunt on the population and on whales that migrate through or stop to feed in the waters off the Washington coast. We also describe information to analyze how an individual gray whale may be affected by a hunt.

[2] Also known as the Pacific Coast Feeding Group (PCFG) whales.

3.4.2 Regulatory Overview

The regulatory information presented for the MMPA and Whaling Convention Act (WCA) in Subsection 1.2, Legal Framework, including the Treaty of Neah Bay and the Makah Tribe's whaling rights, describes the legal processes relevant to our evaluation of the tribe's proposal to resume hunting gray whales. The information in the current subsection focuses on the statutory and regulatory conservation standards that inform our management of cetaceans in general, including gray whales.

GRAY WHALE DEFINITIONS AS USED IN THIS FEIS

Western North Pacific (WNP) gray whales: Gray whales that feed during the summer and fall in the Okhotsk Sea (primarily off northeast Sakhalin Island, Russia), some of which also feed off southeastern Kamchatka in the Bering Sea.

Eastern North Pacific (ENP) gray whales: Gray whales that feed during the summer and fall primarily in the Chukchi, Beaufort, and northwestern Bering Seas, but also as far south as California.

PCFG whales: Gray whales observed in at least 2 years between June 1 and November 30 in the PCFG area (along the U.S. and Canada coasts between 41°N and 52°N, excluding areas in Puget Sound) and entered into the Cascadia Research Collective's photo-identification catalog. For purposes of determining whether a harvested whale is a PCFG whale (i.e., counts against a bycatch or mortality limit) the Tribe's proposal under Alternative 2 would include cataloged whales seen in at least 1 year, while the other action alternatives would include cataloged whales seen in 2 or more years. Alternative 7, the preferred alternative, would assume any whale struck, struck and lost, or approached during the summer hunt time period to be a PCFG whale.

OR-SVI whales: PCFG whales observed in any survey area from southern Oregon to southern Vancouver Island (excluding areas in Puget Sound) from June 1 to November 30.

Makah U&A whales: PCFG whales observed in either the northern Washington survey area (from Cape Alava to Cape Flattery) or Strait of Juan de Fuca survey area (from Cape Flattery to Admiralty Inlet) from June 1 to November 30.

3.4.2.1 Marine Mammal Protection Act Management

NMFS has jurisdiction over cetaceans and most other marine mammals under the MMPA, the primary federal law governing marine mammal conservation and protection in the United States (Subsection 1.2.3, Marine Mammal Protection Act) (the USFWS has jurisdiction over some marine mammals). Therefore, the discussion below describes basic principles of marine mammal management under the MMPA that are relevant to the Tribe's request. The take moratorium, waiver, regulations, and permits are discussed in Subsection 1.2.3.2, Section 101(a) – Take Moratorium and therefore are not addressed here. The requirements of the MMPA help inform the evaluation criteria we use to analyze and compare the alternatives; however, it is not the purpose of this EIS to resolve legal issues.

3.4.2.1.1 Defining Marine Mammal Population Parameters

Optimum Sustainable Population — OSP

The MMPA declares that marine mammals should "not be permitted to diminish beyond the point at which they cease to be a significant functioning element of the ecosystem of which they are a part" and that "consistent with this major objective, they should not be permitted to diminish

below their optimum sustainable population" (OSP) (16 USC 1361(2)). OSP is defined statutorily as "the number of animals which will result in the maximum productivity of the population or the species, keeping in mind the carrying capacity of the habitat and the health of the ecosystem in which they form a constituent element" (16 USC 1362(9)). We have further defined OSP in agency implementing regulations as "a population size which falls within a range from the population level of a given species or stock which is the largest supportable within the ecosystem [known in biological terms as carrying capacity, abbreviated as K] to the population level that results in maximum net productivity level [MNPL]" (50 CFR 216.3). We manage impacts to marine mammal populations according to congressional directives with the goal of maintaining the number of animals within OSP (i.e., between K and MNPL), or, if a population is below OSP, achieving that level. To understand the operating theory of OSP, it is important to understand the biological implications of K and MNPL, the endpoints of the OSP range.

Carrying Capacity — K

K (the upper limit of OSP) is the population level that can be supported in the ecosystem as determined by the natural elements, such as food, predation, temperature, ice cover, etc. As population density increases, birth rates often decrease and death rates typically increase. K is the point at which birth rates and death rates are equal. It is, thus, the number of individuals an environment can support and is the largest size of a density-dependent population at which the population maintains equilibrium (population size neither increases nor decreases). For a particular environment, K will vary by species and can change over time because of a variety of factors, including food availability, disease, competition, predation, environmental conditions, and space. It is possible for a species to exceed its K temporarily.

Maximum Net Productivity Level — MNPL

MNPL (the lower limit of OSP) is a population level related to maximum net productivity, a rate of change defined in NMFS regulations as "the greatest net annual increment in population numbers or biomass resulting from additions to the population due to reproduction and/or growth less losses due to natural mortality" (50 CFR 216.3). In practical terms, MNPL is the population level (i.e., number of animals) that will yield the maximum recruitment into a marine mammal population (i.e., births minus deaths). Sometimes, MNPL is expressed as a fraction of K.

3.4.2.1.2 Calculating Marine Mammal Population Parameters

As implemented by NMFS, K is not the historic but the current carrying capacity of the habitat, without correctable human influence (Gerodette and DeMaster 1990; NMFS 1992a). As described in NMFS (1992a):

> "NMFS has determined that recreating historic carrying capacity before intereference by human activities is not possible in most cases. Instead, NMFS will rely on current carrying capacity and will modify OSP determinations to account for situations where correctable habitat degradation or destruction has been caused by human activities… Where human-cased, correctable degradation of the marine environmental has occurred, OSP levels would reflect K modified (increased) by habitat restoration efforts. If data are available, NMFS would determine K based on the long-term equilibrium population that can be supported under reasonable and proper use of the marine environment and living marine resources."

Gerodette and DeMaster (1990) describe various methods of estimating K. For a population that was hunted or subjected to fisheries bycatch, one method is to start with the present size of the population and back-calculate, using the numbers of animals that were killed by hunting or killed as bycatch. Various researchers used this method to estimate the K value for dolphin populations being incidentally killed in tuna fisheries and for ENP gray whales and bowhead whales (Gerodette and DeMaster 1990). The challenge of this method is that it requires reliable information about several different factors, including present population size and numbers of removals.

Another method described by Gerodette and DeMaster (1990) is to estimate K based on some environmental limiting factor, such as food supply or haulout sites (e.g., the work by Laidre et al. 2011 to estimate carrying capacity of sea otters in Washington State). A third method is to infer K based on an estimate of MNPL. In a logistic model of population growth, MNPL (the lower limit of OSP) is 50 percent of K. However, it is generally accepted that because marine mammals are long-lived with slow rates of reproduction, they have MNPL closer to K (Eberhardt and Siniff 1977).

In the absence of direct measurements of MNPL, we have chosen the model-derived value of 60 percent of K as the MNPL for long-lived marine mammals (45 FR 72178, October 31, 1980). Some researchers have assessed OSP for some species using estimates of abundance over time as the population recovered from exploitation to an equilibrium level. By fitting logistic growth models to the abundance estimates, the researchers have been able to determine the point at which productivity peaked and population growth slowed, indicating the population had passed its MNPL (the lower bound of OSP) (Wade and Perryman 2002; Jeffries et al. 2003; Brown et al. 2005; Punt and Wade 2012).

3.4.2.1.3 Linking Marine Mammal Population Parameters to Removals

A goal of the MMPA is to prevent stocks from diminishing below their OSP (that is, below MNPL). The difficulty of determining whether a stock is at OSP, and how human-caused mortality might affect population abundance relative to OSP, makes it challenging to manage

toward this goal. Given these challenges, NMFS explored other options that specifically focus on human-caused mortality, as reducing this mortality is a primary focus of management efforts. This led to the development of a management tool known as the potential biological removal (PBR) approach that allows NMFS to determine whether particular mortality levels would maintain a given stock within OSP, or allow it to reach OSP if it was below that level. In 1992, NMFS submitted a legislative proposal to Congress outlining the PBR approach which determines the number of individuals that can be removed from a population stock of marine mammals while allowing the stock to recover to, or be maintained within, its OSP (NMFS 1992a).[3]

3.4.2.1.4 Defining and Calculating PBR

Congress amended the MMPA in 1994 to incorporate a regime to govern the taking of marine mammals incidental to commercial fishing operations (section 118); many aspects, including the PBR approach, of the new provision were based on the legislative proposal we submitted to Congress in 1992 (NMFS 1992a). Under 16 USC 1362(20), PBR level is defined as the "maximum number of animals, not including natural mortalities, that may be removed from a marine mammal stock while allowing that stock to reach or maintain its optimum sustainable population."

The MMPA (16 USC 1362(20)) also prescribes a formula for calculating PBR, which is the product of three factors:

$$PBR = N_{min} * 0.5R_{max} * F_r$$

- N_{min} is the minimum population estimate of the stock.
- $0.5R_{max}$ is one-half the maximum theoretical or estimated net productivity rate of the stock at a small population size.
- F_r is a recovery factor of between 0.1 and 1.0.

[3] NMFS and the IWC use different methods to calculate allowable removals from marine mammal populations. Under the MMPA, NMFS applies the PBR approach for certain types of take, which focuses on maintaining marine mammal populations at OSP. The IWC operates under the ICRW, which historically had a harvest focus. The IWC calculates allowable removals or catch limits by focusing on sustainable yield under the maximum sustainable yield model (refer to Subsection 1.2.4.1.3, IWC Aboriginal Subsistence Whaling). The IWC's Scientific Committee advises the IWC on a minimum stock level for each stock, below which whales are not taken, and on a rate of increase towards the maximum sustainable yield level for each stock (footnote to IWC Schedule, Paragraph 13(a)(2)). The ENP gray whale stock is at or above the maximum sustainable yield level (IWC 2022a), so aboriginal subsistence catches are allowed as long as they do not exceed 90 percent of that maximum sustained yield (Paragraph 13(a)(1)).

As long as the total number of animals removed from the population as a result of human sources is no more than the calculated PBR of an affected stock of marine mammals, then the removals will not prevent the stock from recovering to, or being maintained within, its OSP.

3.4.2.1.5 Implementing the PBR Approach

Before implementing the PBR approach, we evaluated whether maintaing human-caused mortality below the PBR level would maintain OSP or allow recovery to OSP. To do this, we selected default values for the parameters of the PBR formula that would meet specific performance criteria and ran simulations in performance trials (Barlow et al. 1995). In these trials, individuals from a hypothetical marine mammal stock were removed from the population at levels up to the calculated PBR each year. One of the following two conditions was satisfied for at least 95 percent of simulation trials: 1) populations at MNPL (i.e., the low end of the OSP range) would remain at that level or above it after 20 years, and 2) populations below OSP (i.e., depleted populations considered as 30 percent of K) would recover to OSP within 100 years. In their conclusions, Barlow et al. (1995) noted that the PBR approach, as recommended and tested, would satisfy the objectives of the MMPA and would facilitate the section 2 mandate to develop marine mammal stocks to the greatest extent feasible. In other words, for marine mammal stocks at OSP, human-caused mortality at or below the PBR level would not cause the stock to fall below OSP, and for marine mammal stocks below OSP, human-caused mortality at or below the PBR level would not prevent the stock from achieving OSP. Wade (1998) reported on more extensive trials simulating the PBR approach and confirmed the major conclusions related to the performance of PBR from Barlow et al. (1995).

Wade and Angliss (1997) describe the results of a NMFS-convened workshop to review the initial PBR guidelines. Workshop participants recommended only relatively minor revisions to the initial guidelines for the use of abundance estimates in calculating PBR. The most notable recommendation was that PBR levels should be reported as unknown when the supporting abundance estimate for the affected marine mammal stock is at least 8 years old, unless there is compelling evidence that the stock has not declined since the last abundance estimate.

3.4.2.1.6 Stock Assessment Reports

Section 117 of the MMPA (16 U.S.C. 1386) requires preparation of a stock assessment report for each recognized marine mammal stock occurring within U.S. jurisdiction. The report must describe the geographic range of the stock; provide a minimum population estimate (Nmin), current and maximum (MNPL) net productivity rates, and current population trend; report human-caused mortality and serious injury by source; describe commercial fisheries that interact

with the stock; categorize the status of the stock according to whether human-caused mortality and serious injury are likely to cause it to be below OSP; and estimate PBR for the stock. The reports are reviewed by the regional scientific review groups and made available for review and comment by the Marine Mammal Commission and the public before they are finalized. The most recent stock assessment report for gray whales is Carretta et al. (2023).

As noted above, in 2005, we adopted new Guidelines for Preparing Stock Assessment Reports pursuant to section 117 of the MMPA and produced a report "Revisions to Guidelines for Assessing Marine Mammal Stocks" (commonly known as GAMMS) (NMML 2005). A workshop of NMFS scientists convened in 2011 recommended revisions to the 2005 GAMMS (Moore and Merrick 2011). The proposed revisions were made available for public comment via a Federal Register notice on January 24, 2012 (77 FR 3450) and in which NMFS emphasized a number of specific issues discussed at the workshop, including:

- Improving stock identification – proposals included 1) specifying whether it is plausible that a stock may actually comprise multiple stocks, and 2) identifying where human-caused mortality or serious injury is concentrated within the range of such a stock.
- Apportioning PBR across feeding aggregations, allocating mortality for mixed stocks, and estimating PBR for transboundary stocks – proposals included 1) ways to apportion and report on mortality or serious injuries, and 2) clarifying when and how to estimate PBR over broad areas with disparate survey data.

Workshop participants also recommended that the criterion for determining when a group of animals should be considered a separate population stock is when it is demographically independent, rather than demographically isolated. The workshop report states:

> "The group agreed to replace references to 'reproductive isolation' and 'demographic isolation' in the Report guidelines with references to 'demographic independence,' as the term 'isolation' is likely to be interpreted by some as implying that there should be no interchange between stocks."

After receiving public comments on the proposed revisions, NMFS finalized the revised guidelines on March 2, 2016 (81 FR 10830) as a NMFS Procedural Directive (NMFS PD 02-204-01). Seven of the nine topics were revised as proposed, including improving stock identification, and replacing "reproductive/demographic isolation" with "reproductive/demographic independence" as described above.

Under the NMFS Policy Directive System, the GAMMS were scheduled for another review in February 2021. In July 2020, NMFS initiated the process to review and revise the guidelines via an internal working group, instead of the usual in-person workshop, due to the COVID-19

pandemic. The working group identified eight topics for potential revisions, which were made available for public comment on August 25, 2022 (87 FR 52368). The 2023 revisions include updated guidance regarding Nmin in post-survey years, strategic stock designations, unobserved mortality and serious injury, incorporation of information on climate change, among other topics. The revised guidelines were finalized on February 7, 2023 (88 FR 7953).

Prior to 2019, the stock assessment process was the appropriate mechanism for designating population stocks of marine mammals under the MMPA. In 2019, NMFS established procedural directive 02-204-03: *Reviewing and Designating Stocks and Issuing Stock Assessment Reports under the Marine Mammal Protection Act* (NMFS 2019a), which separates the stock designation process from the SAR development. Prior to the annual SAR revision, NMFS identifies if "there are (1) any stocks that should be examined for possible revision or (2) potential new stocks that should be added" (NMFS 2019a). The procedural directive outlines examples and criteria for when a stock revision may need to occur, as well as the steps involved in conducting such an assessment.

3.4.2.2 Whaling Convention Act

3.4.2.2.1 Whaling License

Under the WCA (16 USC 916d) and implementing regulations (50 CFR 230.3(b)), no person may engage in whaling without a license. We have by regulation issued a license "to whaling captains identified by the relevant Native American whaling organization" (50 CFR 230.5(a)). We may suspend the license of any captain who fails to comply with NMFS' regulations. Our regulations further specify that any aboriginal subsistence whaling quota shall be allocated to each whaling village or captain by the appropriate Native American whaling organization. At least annually, we are to publish aboriginal subsistence whaling quotas and any restrictions on subsistence whaling in the Federal Register. When we published the first aboriginal subsistence whaling quotas for the use of the Makah Tribe, we also explained the background of the request to the IWC and the relevance of the IWC authorization (see, for example, 63 FR 16701, April 6, 1998).

3.4.2.2.2 Equipment, Crew, Supplies, and Training

WCA section 916d(d) requires an applicant for a whaling license to furnish evidence or an affidavit that the whaling vessel is adequately equipped and competently manned to engage in whaling in accordance with the provisions of the ICRW, the regulations of the IWC, and NMFS' regulations. NMFS' regulations regarding aboriginal subsistence whaling prohibit whaling without adequate crew, supplies, or equipment (50 CFR 230.4(d)). In the past, when we published aboriginal subsistence whaling quotas for the use of the Makah Tribe, we executed agreements

with the Makah Tribal Council that specified the details regarding the supplies, equipment, crew, and training.

3.4.2.2.3 Wasteful Manner Restrictions

WCA regulations prohibit whaling captains from engaging in whaling in a wasteful manner (50 CFR 230.4(k)). Wasteful manner means "a method of whaling that is not likely to result in the landing of a struck whale or that does not include all reasonable efforts to retrieve the whale" (50 CFR 230.2). Related to reasonable efforts to retrieve any whale, WCA regulations also require whaling captains to use harpoons, lances, or explosive darts that bear a permanent distinctive mark identifying the whaling captain (50 CFR 230.4(j)). The mark allows struck and lost whales that wash ashore, or are found later, to be identified and reported as struck and lost whales. WCA regulations also prohibit whaling for any calf or parent accompanied by a calf (50 CFR 230.4(c)).

3.4.2.2.4 Recording and Reporting

WCA regulations require the Native American whaling organization to monitor the hunt, keep a tally of the number of whales struck and landed, and close the season when the quota is reached (50 CFR 230.7(b)). Whaling captains must provide oral or written reports on whaling activities to the Native American whaling organization, including, but not limited to, striking, attempted striking, or landing of a whale, and (where possible) specimens from a landed whale (50 CFR 230.8(b)). The report must include information on the number, dates, and locations of each strike, attempted strike, or landing; the length and sex of the whale landed; and an explanation of the circumstances involving any whale struck and not landed. We are also authorized to provide technical assistance to facilitate prompt reporting and collection of specimens from landed whales, including, but not limited to, ovaries, ear plugs, and baleen plates (50 CFR 230.8(b)). Following the 1999 and 2000 hunts, the NMFS' observers to the hunt provided their own reports to NMFS (Gosho 1999; Gearin and Gosho 2000). The Makah Tribe and NMFS also published a joint report for the 1999 hunt (NMFS and Makah Tribal Council 2000).

3.4.3 Existing Conditions

3.4.3.1 General Life History and Biology

3.4.3.1.1 Identifying Physical Characteristics

Adult gray whales are 36 to 50 feet (11 to 15 m) long and weigh between 16 and 45 tons; females are larger than males. Gray whales have two to five deep longitudinal creases on their throats, and their heads appear narrowly triangular when viewed from above; there is no head ridge (Leatherwood et al. 1982). Gray whales have a dorsal hump followed by a series of bumps or

"knuckles" along the back. Body coloration varies from light to dark gray and is typically mottled and covered with barnacles, scrape marks, and whale lice (Calambokidis et al. 1994). Scientists are able to identify individual whales using the shape of the dorsal hump, knuckle patterns, body scars, and coloration (Darling 1984; Calambokidis et al. 2004a). Gray whales have two blowholes that are side-by-side on top of their heads and can produce a large and distinctive V-shaped blow when they exhale. Migrating gray whales surface to breathe at regular intervals, generally blowing three to five times at intervals of 30 to 50 seconds, then lifting their flukes and submerging for 3 to 5 minutes (Leatherwood et al. 1982). Gray whales usually make shallow dives of 13 to 400 feet (4 to 120 m) to feed (Jones and Swartz 2009).

3.4.3.1.2 Global Distribution and Population Structure

Historically, gray whales occurred in both the North Pacific and North Atlantic Oceans (Fraser 1970; Mead and Mitchell 1984) but are currently found only in the North Pacific Ocean (Rice et al. 1984). At one time, the whales may have accessed both the Pacific and Atlantic Oceans by swimming through migratory corridors in the Arctic (Gilmore 1978), but the distribution of the species changed, likely due to periodic closures of the Bering Sea during ice ages (Swartz et al. 2006). Glaciation dropped sea levels and exposed underlying continental shelf regions, including the Bering Isthmus, which effectively blocked access to the Arctic (Berta and Sumich 1999). Gray whales disappeared in the North Atlantic by the end of the seventeenth century (Mead and Mitchell 1984). However, two anomalous sightings have occurred—one in the Mediterranean Sea in 2010 and one in the South Atlantic in 2013, suggesting that the present reduction in Arctic ice may someday allow gray whales to re-inhabit the North Atlantic (Scheinin et al. 2011; Elwen and Gridley 2013; Hoelzel et al. 2021).

U.S. and international management authorities, including NMFS and the IWC, have identified two populations for this species: an ENP and a WNP population (IWC 2018a; Carretta et al. 2023).[4] These populations are also recognized as separate subpopulations by the International Union for Conservation of Nature (IUCN) (Reilly et al. 2008). Genetic studies using both mitochondrial and microsatellite markers[5] have found statistically significant differences between

[4] Both NMFS and the IWC also commonly refer to these populations as "stocks" (e.g., in NMFS' Stock Assessment Reports), although the IWC's stock definition may not be equivalent to a stock as defined under the MMPA. Also, WNP gray whales are sometimes referred to as the "Korean stock" while ENP gray whales are occasionally termed the "California stock."

[5] Mitochondrial DNA (commonly referred to as mtDNA) is maternally inherited and provides information about historic gene flow of females only. Microsatellites are short segments of nuclear DNA inherited from both parents and reflect gene flow of both males and females.

the two populations (LeDuc et al. 2002; Meschersky et al. 2015; Lang et al. 2022; Brüniche-Olsen et al. 2021). Lang et al. (2022) noted that the significant but low level of differentiation may reflect recent divergence of the two populations as well as some limited degree of interchange between them. Genetic analysis showed that although there was apparent ENP admixture (i.e. interbreeding) in some of the individuals sampled off Sakhalin Island, Russia, as well as those sampled in the Mexican wintering lagoons, the analysis revealed significant genetic differences between the two locations (Lang et al. 2022). Although some have speculated that the observed movements of whales between the WNP and ENP (refer to Subsection 3.4.3.2.1, WNP Seasonal Distribution, Migration, and Movements) signifies a lack of gray whale population structure (Bickham et al. 2013), the results of the aforementioned genetic comparisons represent the best available science and clearly demonstrate that significant mitochondrial and nuclear genetic differences exist between whales sampled in the ENP and those sampled on the feeding ground off Sakhalin Island in the WNP (Lang et al. 2022).

In addition, there is emerging evidence for possible substructure within the ENP population, specifically a PCFG that exhibits seasonal fidelity to feeding grounds off the west coast (Subsection 1.1.3, Summary of Gray Whale Status). After reviewing results from photo-identification, telemetry, and genetic studies available in 2010 (i.e., Calambokidis et al. 2010; Mate et al. 2010; Frasier et al. 2011), the IWC agreed that the hypothesis of the PCFG[6] being a demographically distinct feeding group was plausible and warranted further investigation (IWC 2011a). The term 'feeding aggregation' has been used in scientific literature to describe concentrations of feeding whales (e.g., Berzin 1984; Calambokidis et al. 2002). Research by Lang et al. (2014) provided further support for recognizing the PCFG as a distinct feeding aggregation. These researchers compared genetic markers from whales in the southern (i.e., in the seasonal PCFG range) and northern feeding areas (north of the Aleutians, principally near Chukotka, Russia and Barrow, Alaska). They found that samples from whales demonstrating site fidelity to the southern feeding area (i.e., whales sighted over 2 or more years) had mtDNA patterns that were marginally but significantly different from whales sampled in northern feeding areas, which included samples collected off Chukotka, Russia. However, no significant differences were found when microsattelite allele frequencies were compared between whales representing the PCFG and

[6] The PCFG is defined by the IWC as follows: gray whales observed between June 1 to November 30 within the region between northern California and northern Vancouver Island (from 41° N to 52° N) and photo-identified within this area during 2 or more years (IWC 2011a; IWC 2011b; IWC 2011c).

those sampled on northern feeding areas or the Mexican wintering lagoons (D'Intino et al. 2013; Lang et al. 2014). These genetic studies concluded that 1) structure is present among gray whales using different feeding areas, 2) matrilineal fidelity plays a role in creating such structure, and 3) individuals from different feeding areas may interbreed. Although NMFS concluded that the PCFG did not currently warrant designation as a stock, these findings led the agency to state in the stock assessment report that the PCFG may warrant consideration as a stock in the future. Accordingly, NMFS expanded the ENP stock assessment report to include informational abundance, PBR, and human-caused mortality estimates for PCFG whales (Carretta et al. 2023). The issue of stock structure of the PCFG is discussed in more detail in Subsection 3.4.3.4, Pacific Coast Feeding Group (PCFG) of Gray Whales.

The annual migration of gray whales is a conspicuous but unexplained feature of their behavioral repertoire. Some hypotheses offered to explain migratory behavior focus on benefits to newborn calves (e.g., thermoregulation, protected "nursery areas," etc.) and some do not (e.g., resource tracking, the evolutionary "holdover" hypothesis, etc.) (Corkeron and Connor 1999). Corkeron and Connor (1999) propose that migration to low latitude areas provides a major selective advantage for pregnant female whales in that it reduces the risk of killer whale (*Orcinus orca*) predation on their newborn calves. Killer whales are substantially more abundant in high latitudes, and this is where most attacks on gray whale calves have been observed. Seasonally predictable sources of food have broadly shaped gray whale life history into two major periods: summers, when whales feed in higher latitudes with abundant food and minimal sea ice, and winters, when whales migrate to lower latitudes to escape sea ice and inclement weather and to nurture newborn calves in warmer waters (Swartz 1986; Swartz et al. 2006). Gray whales feed opportunistically on a diversity of prey species throughout their entire range (Nerini 1984). Similarly, they breed in the late fall in their summer range at the onset of the southward migration, breed and calve along the migratory corridor, and breed and calve in the winter on the winter grounds (Rice and Wolman 1971). The summer range is primarily a feeding area but also serves as a weaning and, potentially, a breeding area late in the season. The winter range is primarily a resting and nursing area, although some breeding also occurs. The migratory corridor supports a continuum of behaviors (feeding, breeding, and calving) as whales shift between summer and winter ranges.

Gray whale distribution and habitat use are dynamic, varying seasonally and year-to-year in response to changes in the prey base and the physical properties of the ocean environment (Subsection 3.4.3.1.4, Feeding Ecology and Role in the Marine Ecosystem) (Yablokov and

Bogoslovskaya 1984; Darling et al. 1998; Gardner and Chávez-Rosales 2000; Dunham and Duffus 2001; Feyrer and Duffus 2011). Additionally, the species can shift its range over longer time frames in response to long-term environmental variability such as oceanic climate cycles (Pyenson and Lindberg 2011).

During summer and fall, most whales in the ENP population feed in the Arctic (Chukchi, Beaufort, and Bering Seas) (Figure 3-3). An exception to this generality is the relatively small number (100s) of whales that summer and feed along the Pacific coast between Kodiak Island, Alaska and northern California (Darling 1984; Calambokidis et al. 2002; Gosho et al. 2011; Calambokidis et al. 2014). These whales include animals north of the PCFG area (i.e., northern British Columbia), as well as PCFG animals and 'stragglers,' 'transients,' or 'visitors' (IWC 2012e; Calambokidis et al. 2014; Carretta et al. 2014) that have only been seen feeding in the PCFG area in a single year (presumably using feeding grounds north of the PCFG area in other years). By late November, the southbound migration is underway as ENP whales begin to travel from summer feeding areas to wintering areas associated with lagoons off the west coast of Baja California, Mexico and the southeastern Gulf of California (Rugh et al. 2001; Swartz et al. 2006).

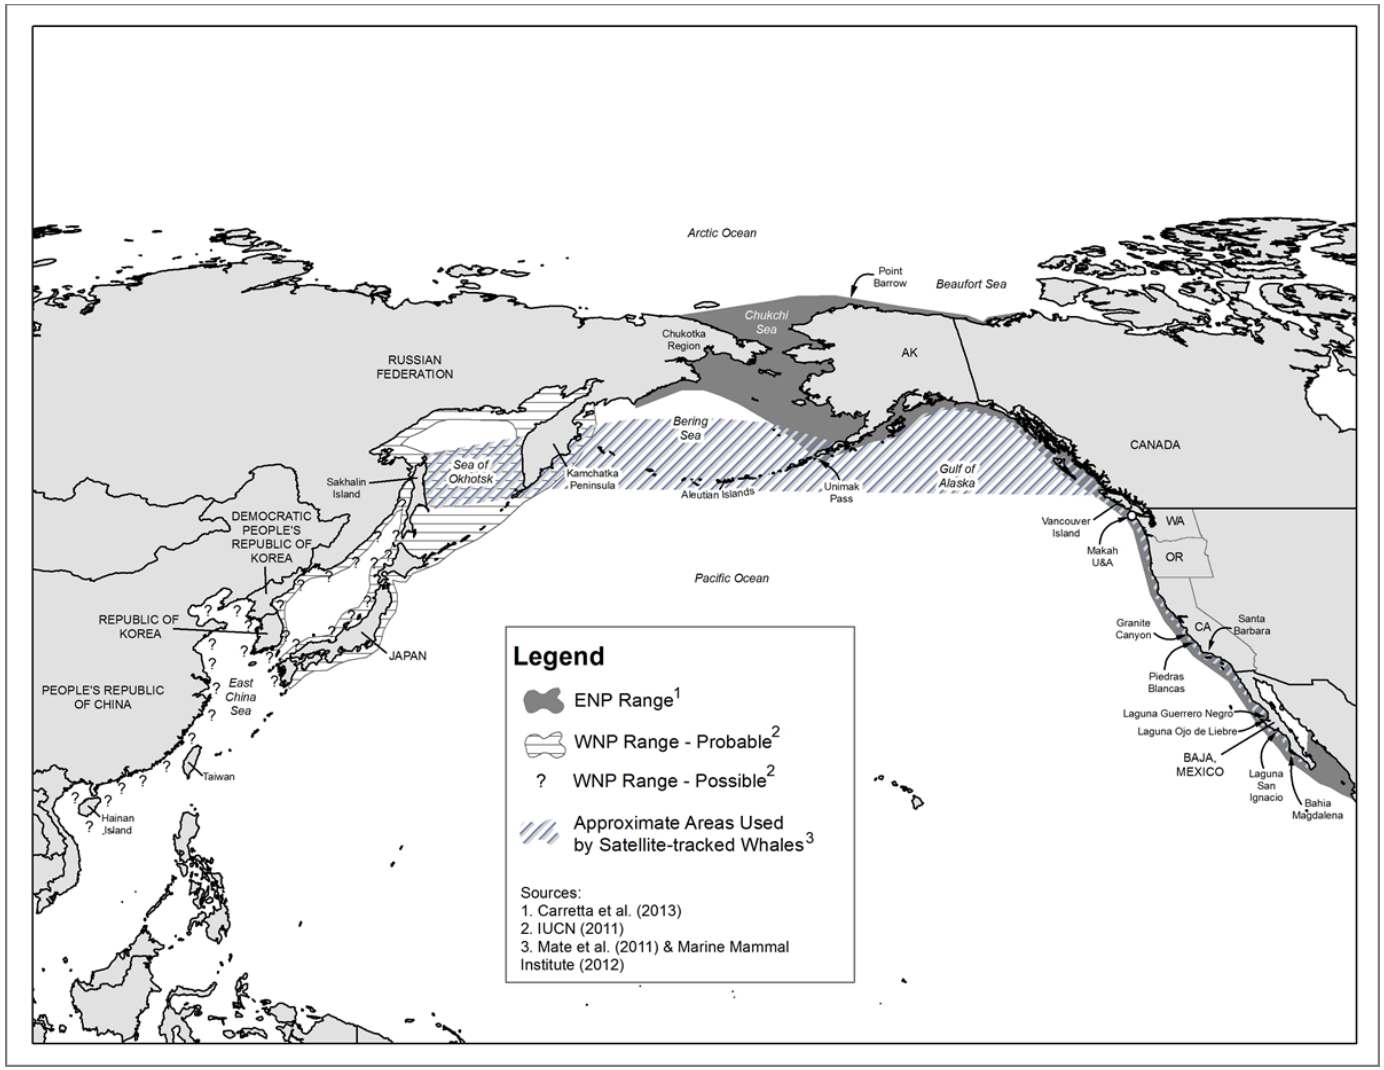

Figure 3-3. Approximate rangewide distribution of the ENP and WNP gray whale populations.

The distribution and migration patterns of gray whales in the WNP are less clear. The main feeding ground is off the northeastern coast of Sakhalin Island, Russia in the Okhotsk Sea, but some animals occur off eastern Kamchatka and in other coastal waters of the northern Okhotsk Sea (Figure 3-3) (Weller et al. 2002; Vertyankin et al. 2004; Tyurneva et al. 2010). Some WNP whales are thought to migrate south along the coast of Asia in the fall, but the migration route(s) and winter ground(s) are poorly known. Information collected over the past century indicates that the gray whale range in the WNP is much more restricted than it was historically (Reeves et al. 2008), and that whales once migrated along the coasts of Japan and South Korea (Andrews 1914; Mizue 1951; Omura 1984) to wintering areas somewhere in the South China Sea, possibly near Hainan Island (Wang 1984). No sightings off South Korea have been reported since 1977 (Park 1995; Kim et al. 2013), although an unconfirmed sighting off South Korea was reported in 2015 (Kim et al. 2018).

Photo-identification (Urbán-Ramirez et al. 2012, 2019; Weller et al. 2012; Martinez-Aguilar et al. 2022a), genetic (Lang et al. 2010; Lang et al. 2022), and telemetry studies (Mate et al. 2011; 2015) have documented that some gray whales observed on the feeding grounds in the WNP migrate to and from the ENP. Such documentation includes: 1) eleven whales photographically matched from off of Sakhalin Island and/or southeastern Kamchatka and waters off of California or the Pacific Northwest, 2) four whales genetically matched from samples off of Sakhalin to and on the ENP migratory route, 3) 48 whales photographically matched from Sakhalin Island and/or southeast Kamchatka to those sighted in Mexican wintering lagoons, and 4) three satellite-tagged whales that migrated from Sakhalin Island to the west coast of North America, with one whale tracked from the WNP to Baja Mexico and back to the WNP over the course of 408 days (August 2011 to October 2012) (Mate et al. 2011; 2015). In combination, these studies have recorded a total of 60 gray whales known to have traveled between the eastern and western North Pacific.

Although these studies show that some whales use both the ENP and WNP, significant mtDNA and nuclear DNA differences exist between samples of whales summering in the WNP and samples of those summering in the ENP (Lang et al. 2022). In addition, gray whales in the WNP and the ENP have exhibited different rates of recovery and levels of abundance following overexploitation as a result of commercial harvest (Rugh et al. 1999; Swartz et al. 2000; Swartz et al. 2006). Bickham et al. (2013) identified several hypotheses regarding the potential stock structure of North Pacific gray whales, and in April 2014 the IWC Scientific Committee convened a rangewide workshop that included a review of these and other hypotheses (IWC 2014b). A key objective of that meeting was to begin developing a modeling framework to better

assess the status (including stock structure and movements) of North Pacific gray whales. Workshop participants reviewed a number of potential hypotheses for inclusion in the modeling framework. Currently, the following two hypotheses are identified as high priority for inclusion in in the modelling framework used for assessing stock status of North Pacific gray whales (IWC 2021a) given available data:

- Hypothesis 4a – Two breeding stocks characterized by maternal feeding ground fidelity. The eastern breeding stock (EBS) consists of northern feeding group (NFG) and PCFG whales, the second, unnamed breeding stock includes western feeding group whales that breed with each other on the migration route to Mexico for overwintering.
- Hypothesis 7a – Three breeding stocks characterized by maternal feeding ground fidelity: the EBS consists of NFG and PCFG whales that overwinter in Mexico, the western breeding stock consists of whales that feed in the WNP and overwinter in the South China Sea, the third, unnamed breeding stock consists of whales that feed in the WNP and breed with each other on the migration route to Mexico for overwintering.

In 2023, NMFS convened a status review team (SRT) to determine whether WNP gray whales qualify as a DPS under the ESA. The SRT evaluated three separate WNP groups that they determined warranted consideration as a DPS under the ESA. They concluded that a combined unit of animals that remain in the WNP year-round and that migrate to the ENP during the winter was most appropriate for designation as a DPS (see Subsection 3.4.3.2.2, WNP Population Structure for more detail) (Weller et al. 2023; NMFS 2023c).

3.4.3.1.1 Population Exploitation, Protection, and Status

Both WNP and ENP populations were greatly reduced by commercial whaling that began in the mid-19th century and continued as late as the 1960s for WNP gray whales (Swartz et al. 2006; Weller et al. 2002). For WNP gray whales, Yablokov and Bogoslovskaya (1984) speculated that pre-exploitation numbers may have been between 1,500 and 10,000 individuals, and Berzin and Vladimirov (1981) estimated only 1,000 to 1,500 remaining WNP gray whales by 1910. However, Weller et al. (2002) noted that it is unclear how the estimates from pre-exploitation and 1910 were derived. Bradford (2003) concluded that at least 1,868 WNP gray whales were harvested in the 20th century, predominantly by commercial whalers off the Korean Peninsula between 1905 and 1935. WNP gray whales were thought to be extinct as recently as the 1970s (Bowen 1974); however, more recent reports and research efforts indicate that a small relic WNP population still exists (Weller and Brownell 2012; Cooke et al. 2013).

From 1845 to about 1900, American whalers hunted gray whales in the ENP from the winter grounds in Baja to the summer feeding areas in the subarctic. Scammon (1874) and Henderson (1984) estimate that approximately 11,300 whales from the population were killed between 1845 and 1874. A more recent assessment by Reeves et al. (2010) estimates that the number of gray whales killed was likely lower (between 6,124 and 8,021 animals) and may not have accounted for calves that were killed or orphaned and presumably died. Punt and Wade (2012) reported a similar commercial catch estimate of 8,300 gray whales between 1846 and 1874 and noted that catch estimates prior to 1930 are subject to considerable uncertainty. Hunts in and near the Baja California lagoons greatly reduced the reproductive capacity of the population by killing the females with calves (Swartz et al. 2006; Reeves et al. 2010).

From approximately 1914 to 1946, modern industrial whaling by the United States, Japan, Norway, and the Soviet Union in the North Pacific took an estimated 940 gray whales (Reeves 1984). Estimates of ENP gray whale abundance before commercial exploitation vary. Henderson (1984) estimated that the original population was between 15,000 and 20,000 whales. Reilly (1981) estimated that there may have been 24,000 gray whales before 1846. Scammon (1874) proposed that the population numbered about 30,000 whales from 1853 to 1856. After the heavy exploitation of gray whales, especially from 1855-1874, the abundance may have dropped to only a few thousand animals (Henderson 1984).

More recently, Alter et al. (2007 and 2012) used estimates of genetic diversity to infer that the pre-whaling abundance of gray whales may have been approximately three to five times more numerous (76,000 to 118,000) than the average census size at the time of publication (22,000). Alter et al. (2007) note that their estimate likely measures both the ENP and WNP stocks together and that an important question is whether carrying capacity has declined over time. If it has, then ENP gray whales may be reduced from historical numbers but may have reached an alternative stable state with a lower carrying capacity today (refer to Subsection 3.4.3.3.4, ENP Status, Carrying Capacity, and Related Estimates).

Estimates of ENP gray whale abundance after commercial exploitation vary. Reilly (1981) estimated that the population declined to below 12,000 whales; Henderson (1984) estimated that the population did not exceed 8,000 to 10,000 whales; and Butterworth et al. (2002) estimated a number between 4,000 to 5,000 whales, down to as low as 1,500 to 1,900 whales after commercial whaling stopped in 1937 and 1938. Since then, gray whales have been protected pursuant to a suite of international agreements and federal laws (refer to Subsection 1.2, Legal Framework). The list below includes a summary of these efforts and expands on the protection

provided under the ESA. Although ENP gray whales were removed from the ESA list of endangered species in 1994, the history of their listing and de-listing provides relevant context for analysis of the Makah Tribe's request.

1. 1937 International Agreement for the Regulation of Whaling — The 1937 Agreement protected gray whales from commercial whaling but included certain exceptions, including to allow for aboriginal subsistence use and scientific research. Norway, the United States, and others signed the Agreement in 1937 (Reeves 1984), and Canada, the Soviet Union, and Japan signed it in 1938, 1946, and 1951, respectively.

2. 1946 International Convention for the Regulation of Whaling — The ICRW continued the 1937 Agreement's prohibition on commercial whaling of gray whales, as well as allowing aboriginal subsistence and scientific whaling (refer to Subsection 1.2.4.1, International Whaling Governance under the ICRW for more detail). Consequently, since 1951, all nations with factory ships operating in the North Pacific Ocean have been subject to the provisions protecting gray whales from commercial whaling (Reeves 1984). During the fall southward and spring northward migrations between 1959 and 1969, scientists in the United States took 316 gray whales off the coast of central California under IWC special research permits to establish the status of the population (Rice and Wolman 1971).

3. Whaling Convention Act — The WCA prohibits commercial whaling in the United States and authorizes aboriginal subsistence whaling consistent with the IWC Schedule (i.e., regulations of the IWC that are an integral part of the ICRW) (refer to Subsection 1.2.4, Whaling Convention Act, for more detail).

4. Endangered Species Act — The gray whale (i.e., the entire taxonomic species) was listed as an endangered species under the statute preceding and replaced by the ESA (35 FR 8495, June 2, 1970). Following a comprehensive evaluation of its status (Breiwick and Braham 1984), NMFS concluded on November 9, 1984 (49 FR 44774) that the population should be listed as threatened, instead of endangered. On November 22, 1991, NMFS proposed to remove the gray whale population from the list of endangered and threatened wildlife (56 FR 58869). NMFS published a final notice of determination (58 FR 3121, January 7, 1993) to remove the population from the list because the species had recovered to near its estimated original population size and was neither in danger of extinction throughout all or a significant portion of its range, nor likely to again become endangered within the foreseeable future. On June 16, 1994 (59 FR 21094), the ENP gray

whale population was formally removed from the list of endangered and threatened wildlife. The WNP stock remained on the list as an endangered species. As required under section 4(g) of the ESA, we drafted a plan to monitor the status of the ENP stock for at least 5 years following the delisting. A comprehensive status review, completed in August of 1999, recommended that the population continue under a non-threatened classification (Rugh et al. 1999).

In 2001, we received a petition to relist the gray whale under the ESA but found that the petition did not present substantial scientific or commercial information indicating that relisting was warranted (66 FR 32305, June 14, 2001). We have continued monitoring the population since delisting.

5. Marine Mammal Protection Act — The MMPA established a moratorium on the taking of all marine mammal species, including gray whales, with certain exemptions and exceptions (Subsection 1.2.3, Marine Mammal Protection Act). The agency publishes annual stock assessment reports for gray whales and other marine mammals, as required by section 117 of the MMPA (Subsection 3.4.2.1.6, Stock Assessment Reports).

   On October 21, 2010, NMFS received a petition requesting a status review under the MMPA for the ENP stock of gray whales but found that the petition did not present substantial information indicating that a status review may be warranted (75 FR 81225, December 20, 2010). NMFS released the most recent stock assessment report for ENP gray whales in July 2023 (Carretta et al. 2023). The report was reviewed by the independent scientific review group (established under the MMPA) and made available for comment by the Marine Mammal Commission and the public. This report, along with the scientific information cited therein, summarizes the best available scientific information on the status of the ENP gray whale stock.

The WNP population was listed as critically endangered by the IUCN in 2000 (Hilton-Taylor 2000; Reilly et al. 2000; Baillie et al. 2004). The most recent population assessment (Cooke 2017; Cooke et al. 2018) resulted in a median estimate of 290 individuals of age 1+ (non-calf), with a 90 percent confidence interval of 271 to 311 individuals. The estimated population growth rate over the 10 years from 2006 to 2016 was 2.8 percent per annum (±0.8 percent).

In contrast, the ENP population is thought to have recovered to pre-exploitation numbers, and it was removed from the endangered species list in 1994 (59 FR 21094, June 16, 1994) after 3 decades of research supported the conclusion that it had recovered (Buckland and Breiwick

2002). The most recent abundance estimate for the ENP population is 14,526 whales (Eguchi et al. 2023a), and the PCFG population currently numbers 212 whales (Harris et al. 2022). Washington State, in the latest Periodic Status Review, maintained that gray whales are a "state sensitive" species due to the presence of WNP and PCFG gray whales in Washington and the current status of threats (Sato and Wiles 2021).

Based on their conclusion that there may have been as many as 118,000 gray whales historically, Alter et al. (2007) concluded that the ENP stock should be designated as depleted based on genetic approach to estimating historic abundance. NMFS rejected this conclusion for the following reasons: 1) the analysis of Alter et al. (2007) included both the WNP and the ENP, and may have included Atlantic gray whales as well, whereas NMFS' stock assessments are based on individual stocks and "it is speculative to try to determine what proportion of the estimated abundance may have been in the eastern or western populations," and 2) NMFS relies on current carrying capacity in making MMPA determinations and "an estimate of stock abundance 1,100 to 1,600 years ago is not relevant to MMPA decision-making, even if such an estimate were available."

PCFG whales are not recognized by NMFS as a separate population stock, but we have determined that these whales appear to be a distinct feeding aggregation and may warrant consideration as a stock in the future (Carretta et al. 2023). Given this possibility, and because the Tribe's request specifically addresses the potential for "local depletion" of gray whales in the Tribe's U&A, we have included PCFG-related sections in this FEIS where appropriate.

3.4.3.1.2 Feeding Ecology and Role in the Marine Ecosystem

Gray whales use various feeding techniques, including 1) suction feeding, also called benthic feeding or bottom feeding, which allows them to feed on crustaceans that live burrowed in (infauna) and just above (epifauna) the sea floor; and 2) engulfing or skimming prey in the water column and on the sea surface. This broad foraging capability allows gray whales to feed on a wide variety of prey throughout their range (Nerini 1984; Darling et al. 1998; Dunham and Duffus 2001; Moore et al. 2003; Moore et al. 2007; Budnikova and Blokhin 2012). Pyenson and Lindberg (2011) hypothesized that flexibility in feeding modes and migratory behavior allowed gray whales to survive major, glacially-driven changes in sea levels and available foraging habitat during the Pleistocene. Such flexibility may account for the gray whale's more rapid recovery from commercial whaling when compared with other large whale species (Nerini 1984; Moore et al. 2001).

Gray whales regularly consume benthic prey (Nemoto 1970; Nerini 1984), often creating furrows or pits and leaving a tell-tale plume of mud in the water column (Johnson and Nelson 1984; Nerini 1984; Kvitek and Oliver 1986; Weitkamp et al. 1992). Gray whales display an adaptation to bottom feeding because their baleen plates are thicker and the hairs are coarser and stronger than those of other whales. This allows them to excavate coarse bottom sediments on a regular basis (Nemoto 1959; Nerini 1984). Nerini (1984) and more recently Budnikova and Blokhin (2012) and Budnikova et al. (2013) listed prey obtained from gray whale stomachs comprising up to 33 genera, including a wide variety of benthic and epibenthic invertebrates, such as amphipods, decapods, molluscs, polychaete worms, algae, and sponges. Moore et al. (2007) and Gosho et al. (2011) also documented tens to hundreds of gray whales feeding off Kodiak Island, primarily on epibenthic marine crustaceans commonly referred to as hooded shrimp. Fadeev (2011) and Vladimirov et al. (2012) noted that the primary prey of WNP gray whales are benthic amphipods, but noted circumstantial evidence that they also feed on sandlance near Sakhalin's Piltun Lagoon. Various studies in the PCFG area have affirmed that gray whales are opportunistic foragers on a wide variety of prey species, including mysids, crab larvae, amphipods, ghost shrimp, clams, and herring eggs/larvae (Murison et al. 1984; Darling et al. 1998; Dunham and Duffus 2002; Coyle et al. 2007; Nelson et al. 2008; Newell 2009; Feyrer 2010; Feyrer and Duffus 2011; Lindsay 2013; Burnham and Duffus 2016; Hildebrand et al. 2021; 2022).

Excavation of bottom sediments by feeding gray whales may play a role in maintaining the benthic habitat in some areas, though its relative importance is not clear. Some investigators hypothesize that gray whale benthic feeding may help maintain the substrate (Johnson and Nelson 1984; Oliver and Slattery 1985) or otherwise have an important influence on the benthic community (Nelson and Johnson 1987; Grebmeier et al. 1989; Burnham and Duffus 2016). Excavated sites also trap woody debris, which affects benthic productivity (Oliver and Slattery 1985). Gray whale excavation has been proposed as a major source of disturbance and part of a cycle of exploitation, recolonization, succession, and maturing of the prey community (Nerini 1984; Oliver et al. 1984; Oliver and Slattery 1985). Conversely, some investigators have proposed that the growing gray whale population has reached carrying capacity and that the population's overexploitation of benthic amphipods in the Bering Sea may have led to a decrease in amphipod abundance during a documented period from 1986 to 1988 (Highsmith and Coyle 1992). It has further been suggested that gray whale foraging can lead to localized loss of amphipod or other prey communities, forcing whales to forage elsewhere (Highsmith and Coyle 1992; Weitkamp et al. 1992; Feyrer 2010; Feyrer and Duffus 2011). In the action area, gray whales may be feeding on both pelagic and benthic prey (Lindsay 2013; Scordino et al. 2014a).

Gray whales excavating the benthos may also make food available for surface-feeding seabirds. As the whales stir up the benthos, particularly in shallow waters, feed rises to the surface. Observations in the Bering Sea suggested this association (e.g., Grebmeier and Harrison 1992), but no similar observations have been made in the action area. When gray whales die, decomposing whale carcasses also deliver large pulses of organic material to the seafloor. This material may serve as islands of habitat for unique assemblages of deep-sea macrofauna (Dahlgren et al. 2004; Goffredi et al. 2004). Barrett-Lennard et al. (2011) speculated that the frequent occurrence of gray whale carcasses (as a result of predation by killer whales) in shallow waters and beaches near Unimak Pass, Alaska, may affect the structure of bear and shark populations that scavenge on the remains. These authors also report on an apparent shallow water carcass-storing behavior that may promote the development and cultural transmission of specialized feeding behaviors by the area's killer whale population.

Although gray whales are consistently characterized as benthic feeders in the literature, they also feed on pelagic prey, including mysid crustaceans, crab larvae, herring eggs and larvae, sandlance, ghost shrimp, and euphausiids (Murison et al. 1984; Nerini 1984; Oliver et al. 1984; Weitkamp et al. 1992; Duffus 1996; Darling et al. 1998; Benson et al. 2002; Dunham and Duffus 2002; Nelson et al. 2008; Stelle et al. 2008; Newell 2009; Brownell et al. 2010; Feyrer and Duffus 2011; Lindsay 2013; Scordino et al. 2014a). They feed in the water column by making short dives and random movements in kelp beds and within the surf zone of rocks and islets (Murison et al. 1984; Nerini 1984; Darling 1998). When they skim feed on the sea surface, they move along the surface, biting down on plankton streams along the tide line (Darling 1998).

Over the years, researchers have observed gray whales aggregating in particular areas to feed where prey densities are high, especially in areas of benthic prey densities in the northern seas (e.g., Berzin 1984; Yablokov and Bogoslovskaya 1984; Clarke and Moore 2002; Moore et al. 2000; Moore et al. 2003; Highsmith et al. 2007). Areas where whales congregate to feed on a regular basis have been referred to as 'feeding grounds' or 'feeding areas' (e.g., Berzin 1984; Calambokidis et al. 2002; Moore et al. 2003; Calambokidis et al. 2004a), though the whales also feed continuously along their migration route (e.g. Vancouver Island, Burnham and Duffus 2022) and in Mexican lagoons (Gelippi et al. 2022). Some scientists have proposed that whales primarily feed on benthic prey in higher latitudes and switch to pelagic prey in lower latitudes (Nerini 1984), or that prey are in primary, secondary, or tertiary feeding grounds with pelagic prey occurring further south in the range (Kim and Oliver 1989). Others have proposed that whales select pelagic prey first when available because it is easier to obtain than benthic prey

(Dunham and Duffus 2001). Dunham and Duffus (2001) hypothesize that pelagic prey concentrate in the water column, making a relatively easy filter-feeding target and that the distribution of pelagic prey is not as patchy or unpredictable as benthic prey.

Rather than exhibiting strong regional or prey-type preferences, whales probably exhibit highly flexible and opportunistic foraging behavior using a variety of prey resources, both benthic and pelagic, within a given feeding area (Darling et al. 1998; Dunham and Duffus 2001, 2002; Fadeev 2011; Feyrer and Duffus 2011; Vladimirov et al. 2012). After 26 years of observations off the southwest coast of Vancouver Island, some researchers noted that whales could be observed feeding in discrete pockets of habitat over short time frames, depending on prey availability. Over longer time frames, however, virtually all of the southwest coast study area was used by feeding gray whales (Darling et al. 1998; Dunham and Duffus 2001). Darling et al. (1998) proposed that gray whales are attuned to natural patterns of abundance and absence occurring within a prey assemblage and that different prey species play equal roles over a season or several years.

The best available information indicates that feeding aggregations (the whales) and feeding areas (the prey) are dynamic, with both small- and large-scale changes over time and space. Gray whales change location and habitat to exploit the optimum prey species at any one time, based on abundance, density, size, caloric content, and predation pressure. Such factors may vary by season and year, depending on environmental variability and the population dynamics of prey (Darling et al. 1998; Clarke and Moore 2002; Moore et al. 2007).

3.4.3.1.3 Reproduction and Calf Production

Gray whale breeding and calving are seasonal and closely synchronized with migratory timing. Sexual maturity is attained between 6 and 12 years of age (Rice 1986; Rice and Wolman 1971; Bradford et al. 2010). The reproductive cycle in female gray whales lasts approximately 2 years and includes copulation, pregnancy, lactation, and a resting period (Yablokov and Bugoslovskaya 1984). A calf therefore can be produced every other year. The sexual cycle is tied to annual migrations and environmental conditions favorable for the early development of calves (Swartz 1986; Swartz et al. 2006). Both male and female gray whales are promiscuous breeders and copulate repeatedly with more than one mate (Jones and Swartz 1984). Mating behavior is observed during most seasons (Gilmore 1960; Rice and Wolman 1971; Jones and Swartz 1984; Swartz 1986; Berta and Sumich 1999).

Female gray whales come into estrous primarily during a 3-week period from late November to early December, which coincides with the onset of the southward migration from the summer feeding grounds to wintering grounds (Rice and Wolman 1971; Shelden et al. 2004). At this time,

ENP whales are known to congregate in nearshore areas of the summer feeding range at or near the top of the migratory corridor, possibly to find mates (Swartz et al. 2006). The mean conception date is approximately December 5 (Rice and Wolman 1971). Mating occurs throughout the southward migration in the migratory corridor. Females that have not successfully bred may enter a second estrous cycle within 40 days (Rice and Wolman 1971), such that a few females may breed as late as the end of January while present on the winter grounds (Jones and Swartz 1984). Estrous females and mature males in the second breeding cycle have been observed in Baja lagoons at highest densities near lagoon inlets and in adjacent coastal waters (Swartz et al. 2006). The gestation period lasts approximately 13.5 months (or approximately 418 days) (Rice et al. 1984), so newly pregnant females can calve about a year later during the winter.

As noted previously, we have a poor understanding of the migration route(s) and winter breeding ground(s) used by gray whales in the WNP. It was believed that these whales migrate along the coasts of Japan and South Korea (Andrews 1914; Mizue 1951; Omura 1984) to wintering areas somewhere in the South China Sea, possibly near Hainan Island (Wang 1984). More recent information from photo-identification and genetic and telemetry studies indicates that some whales winter in the ENP (refer to Subsection 3.4.3.2.1, WNP Seasonal Distribution, Migration, and Movements).

In contrast, we have a much better understanding of the migration route and breeding grounds used by ENP whales. Some gray whales in the ENP calve in the shallow, protected lagoons of Baja Mexico (often referred to in scientific literature as birthing lagoons, calving lagoons, or breeding lagoons), starting around December 26 and ending approximately at the beginning of March (Swartz and Jones 1983; Sánchez-Pacheco 1998), with a median birthdate around January 27 (Rice and Wolman 1971). Since the late 1970s and early 1980s, calf sightings have increased near Carmel (Shelden et al. 2004) and scientists currently believe that perhaps one-quarter to one-half of the calves are born north of Carmel (well north of the Baja lagoons) during the southward migration (Shelden et al. 2004). Shelden et al. (2004) propose that some mothers that reach parturition along the southward migration may winter with their calves in the Southern California Bight, near the Channel Islands, until the calves are large enough to return north.

Calves are approximately 15 feet (4.6 m) long and weigh 1,000 pounds (454 kg) at birth (Rice 1986). The sex ratio of calves is 1:1 for the ENP gray whale (Rice and Wolman 1971; Jones and Swartz 1984), but it is closer to 66 percent males and 34 percent females for whales first identified as calves on the WNP feeding grounds (Weller et al. 2009; Lang 2010). The mothers' rich milk is more than 50 percent fat and nourishes the calves for several weeks while they

prepare for the long northward migration to summer feeding areas. Calves are weaned and become independent by 6 to 8 months of age while on the summer feeding ground (Rice and Wolman 1971; Calambokidis et al. 2010). Gray whale calves are approximately 28 to 30 feet (8.5 to 9.1 m) long before migrating southward (Rice 1986).

Gray whale calf production trends have been monitored in the ENP using three methods:

1. Surveying for calves from shore and from aircraft in central California during the northward migration (Perryman et al. 2002; Perryman et al. 2004; Perryman et al. 2011; Perryman and Weller 2012; Weller and Perryman 2019; Stewart and Weller 2021a; Eguchi et al. 2023b)
2. Counting calves from shore at Granite Canyon, California during the southward migration (Shelden et al. 1995; Shelden and Rugh 2001; Shelden et al. 2004)
3. Conducting aerial and vessel surveys for calves in the lagoons of Baja California, principally Laguna Guerrero Negro, Laguna Ojo de Liebre (most occupied), Laguna San Ignacio, and the Bahia Magdalena Lagoon complex (Urbán-Ramírez et al. 2003; Urbán-Ramírez et al. 2010; Rosales-Nanduca et al. 2012; Swartz et al. 2012; Swartz et al. 2020; Urbán-Ramirez et al. 2018; 2019; 2022)

NMFS' Southwest Fisheries Science Center has conducted shore-based sighting surveys of northward migrating whales annually since 1994 to estimate the number of calves passing Piedras Blancas, California (Perryman et al. 2002, 2021; Eguchi et al. 2023b). Additional research included aerial surveys in 1994 and 1995 to determine offshore distribution, and concurrent replicate watches near the peak of each migration to estimate sightings missed by the standard watch team (Perryman et al. 2002). Data from these surveys, including calf counts, corrected calf estimates (to account for periods not on watch and for calves missed), and calf production indices (calf estimate/total population estimate) are summarized in Table 3-2 and illustrated in Figure 3-3.

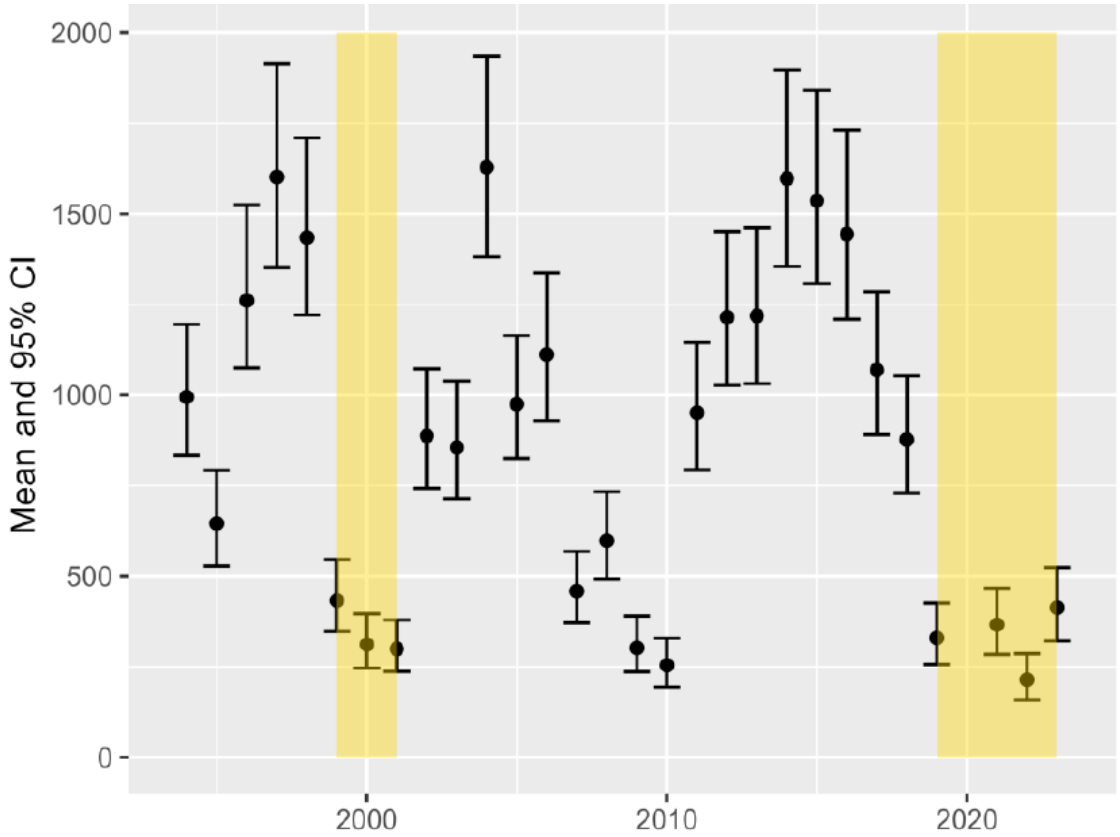

Figure 3-3. Annual estimates of eastern North Pacific gray whale calf production from 1994 to 2023 with associated 95% confidence intervals. Yellow vertical bars indicate unusual mortality events (figure from Eguchi et al. 2023b).

Table 3-2. Eastern North Pacific gray whale calf production from 1994-2023 with mean, median, standard error (SE), 95% lower (LCL) and upper (UCL) confidence limits. Years with unusual mortality events are highlighted in gray (table from Eguchi et al. 2023b).

Year	Mean	Median	SE	LCL	UCL
1994	1,038.9	1,027.0	99.0	873.5	1,254.5
1995	656.3	652.0	69.4	538.5	809.0
1996	1,195.1	1,184.0	108.0	1,016.0	1,420.5
1997	1,632.8	1,619.0	142.6	1,394.0	1,938.0
1998	1,435.6	1,419.0	117.3	1,253.5	1,697.0
1999	484.0	481.0	52.8	395.0	595.0
2000	318.0	315.0	36.9	254.0	403.0
2001	300.8	299.0	36.3	235.5	375.0
2002	922.3	918.0	84.3	771.5	1,105.0
2003	845.2	839.0	77.6	710.5	1,013.6
2004	1,643.4	1,636.0	145.5	1,388.5	1,958.6
2005	1,014.4	1,008.0	93.5	859.5	1,215.0
2006	1,137.6	1,132.0	106.8	958.5	1,373.5
2007	453.9	451.0	50.7	364.0	568.0
2008	612.1	608.0	62.2	501.5	750.5

The calf estimates and calf production index in the ENP indicate that the gray whale population experienced periods of decreased production from 1999 to 2001 and 2007 to 2010. The 1999 to 2001 period coincides with an unusual mortality event that resulted in numerous stranded gray whales in 1999 and 2000 (Gulland et al. 2005) (Subsection 3.4.3.1.7, Strandings). It is apparent that, although calf production dipped from 1999 to 2001, it recovered during 2002 to 2006 (Table 3-2). Perryman et al. (2021) noted the high interannual variability in calf production between 1994 and 2016 and found that environmental indices (the Pacific Decadal Oscillation and the North Pacific Index) in combination with ice cover in the Bering and Chukchi Seas during the early phase of gestation are important factors in explaining the observed variability. They concluded that access to prey early in the gestation period is critical to reproductive success in the ENP population.

Starting in 2019, calf production has been among the lowest years on record (Stewart and Weller 2021b; Eguchi et al. 2022b; Eguchi et al. 2023b), coinciding with the onset of the current UME. Eguchi et al. (2022b) noted that there was a linear relationship between estimated abundance of the ENP population and estimated calf production, suggesting that the factor(s) mediating mortality may also be influencing fecundity. In 2023, the calf production estimate nearly doubled from the year prior (412 in 2023), although Eguchi et al. (2023b) note that the counts are still much lower than in years prior to the current UME.

Additional evidence of changes in calf production comes from observations at the Mexican calving lagoons. Annual mother-calf counts by Urbán-Ramírez et al. (2010) in two of the lagoons (San Ignacio and Ojo de Liebre) closely reflect the variability seen during the 1994 to 2010 period monitored by Perryman et al. (2011), including the steep decline in 1999 to 2001 coincident with the unusual mortality event (Figure 3-4a). The data for Laguna Ojo de Liebre also suggests that there was a significant rebound in mother-calf pairs during 2002 to 2006 (nearly 900 pairs in 2004) followed by another decline to low counts (less than 200 pairs) in 2010 (Figure 3-4a) (Urbán-Ramírez et al. 2010). Swartz et al. (2012) reported that maximum counts of mother-calf pairs in Laguna San Ignacio during 2011 to 2012 were 175 to 232 percent higher than the 2007 to 2010 average counts and that more females appear to be using this lagoon (including females that gave birth elsewhere). These authors speculated that increasing numbers of mother-calf pairs might be a result of new, mature females replacing those that were lost during the 1999 to 2000 unusual mortality event. Swartz et al. (2012) also noted that observations of healthy “fat”

calves and few "skinny" adults in Laguna San Ignacio in 2011 and 2012 suggests that gray whale females had found adequate prey resources during previous summers.

Coincident with the 2019-2023 ENP gray whale UME, Urbán-Ramirez et al. (2022) reported significant declines in winter calf counts in Laguna San Ignacio and Bahía Magdalena between 2018 and 2022 (Figure 3-4b), along with an increase in the percentage of "skinny" and "emaciated" whales (Ronzón-Contreras et al. 2021, Christiansen et al. 2021), increased adult mortality (Martinez-Aguilar et al. 2022b), and an approximately two week earlier departure of whales from the lagoons. However, in 2023, body condition of whales in the lagoons improved and the number of mother-calf pairs in the lagoons increased (LSIESP 2023). The number of calves increased during the spring calf count as well (Eguchi et al. 2023b), suggesting a recent change in these trends.

Calf production in the WNP has been monitored annually since 1995 during photo-identification surveys off Sakhalin Island. Between 1995 and 2021, the number of calves observed ranged from a low of 2 calves in 1995 to 20 calves in 2019 (Table 3-3; Figure 3-5) (Burdin et al. 2022). Unlike the California/ENP counts described above, these WNP counts represent calves that reached the Sakhalin feeding grounds but not those that perished during the potentially lengthy migration from birthing areas. Based on photo-identification studies of the gray whales feeding of Sakhalin Island, Russia, between 1995 and 2009, Bradford et al. (2010) reported on two gray whales—out of 17 females first sighted as calves or yearlings—that were observed to have first produced a calf at the ages of 7 and 11 years.

3.4.3.1.4 Natural Mortality

Sources of natural mortality for gray whales include predation, disease, entrapment in ice, and starvation. In an assessment of the ENP stock, Punt and Wade (2012) estimated that the annual natural mortality of non-calf animals is approximately 2 percent in a normal year. Using an individual-based population model fit to photo-identification data collected from WNP whales, Cooke et al. (2019) estimated that the survival of non-calves is 0.975 (SE=0.005). Killer whales are the primary natural predators of gray whales. In the WNP, Weller et al. (2018) reported that gray whales had a relatively high incidence of killer whale tooth scars compared to estimates

made for other baleen whale populations. Corsi et al. (2022) found that ENP gray whales had a higher incidence of predatory scarring than did eastern North Pacific blue and humpback whales. There are many anecdotal reports of killer whale interactions with gray whales, as well as observations of gray whale carcasses with injuries consistent with probable killer whale predation (Willoughby et al. 2022), but it is difficult to quantify the proportion of the gray whale stock killed or approached by killer whales each year (Rice and Wolman 1971; Fay et al. 1978; Jones and Swartz 1984; Poole 1984; Goley and Straley 1994; George and Suydam 1998). Recent studies indicate that killer whale predation could be common in certain locations. In the False Pass-Unimak Island region of Alaska, over 100 transient killer whales amass in the spring to feed on migrating gray whales (Matkin et al. 2007). In May to early June in 2003 and 2004, Matkin et al. (2007) reported killer whales taking gray whales more frequently than any other species, with 19 harassments, of which 18 resulted in kills. Barrett-Lennard et al. (2011) also found that the gray whales migrating past Unimak Island were vulnerable to predation by killer whales. They observed four gray whales killed and three gray whales harassed by killer whales; attacks would sometimes be terminated after brief harassments. All observed attacks occurred in deep water, where young-of-the-year calves and juveniles were selectively attacked. Killer whale attacks on gray whales were also the most frequently observed predation event off the Chukotka Peninsula (Melnikov and Zagrebin 2005). Of the 92 observed killer whale attacks on marine mammals, 66 percent were on gray whales with nearly 80 percent of them resulting in kills (Melnikov and Zagrebin 2005). In a study by Wade et al. (2007), gray whales accounted for approximately 8 percent of 466 observed predation events by transient killer whales off the west coast of North America; calves and juvenile gray whales were taken preferentially over adults.

Predation by transient killer whales has been suggested as a significant cause of gray whale calf mortality (Barrett-Lennard et al. 2011). Several studies suggest that gray whale calves may be particularly vulnerable during their northward (spring) migration (Ternullo and Black 2002; Ford and Reeves 2008). The majority (85 percent) of the gray whales killed off the Chukotka Peninsula were juveniles (Melnikov and Zagrebin 2005). Of the 15 killer whale attacks described in Ford and Reeves (2008), 14 involved groups of gray whales, and eight involved mothers with young calves. Barrett-Lennard et al. (2011) speculate that gray whale migration patterns likely shift over time because of changes in the distribution and abundance of transient killer whales. For example, these authors suggest that gray whales behave most cryptically and follow shorelines most closely in areas where they have encountered killer whales in the past. Gray whale responses to predatory attacks by killer whales have included swimming towards shore, rolling and turning, slashing

their tail flukes, or a female gray whale defending her young by interposing her body between the killer whales and her calf (Ford and Reeves 2008; Barrett-Lennard et al. 2011).

Other predators of gray whales are sharks, including the great white shark (*Carcharodon carcharias*) and tiger shark (*Galaeocerdo cuvier*) (Jones and Swartz 2002), but the impact of such predation is not known.

3.4.3.1.5 Strandings

A stranding is an event where a marine mammal is dead on a beach or shore or in water within the U.S. EEZ, or a marine mammal is alive on a beach or in shallow water within the EEZ but is unable to return to its natural habitat without assistance (50 CFR 216.3). In the 1992 MMPA Amendments, Congress designated NMFS as the lead agency to coordinate a Marine Mammal Health and Stranding Response Program. Through the Marine Mammal Stranding Network, we oversee, coordinate, and authorize volunteers from network partners including non-profit organizations, aquaria, universities, animal care institutions, veterinarians, wildlife agencies, the Makah Tribe, and state and local governments to respond to marine mammal strandings throughout the coastal states. The NMFS Marine Mammal Health and Stranding Response Team also coordinates with partners in neighboring countries when strandings cross national lines. Stranding network volunteers collect and report stranding data to NMFS, and we maintain a database of gray whale stranding records for Alaska, Washington, Oregon, and California. We also have access to some stranding data from Canada and Mexico, but only limited access to stranding data from Asia. Strandings are known to occur in the WNP (see review by Weller and Brownell 2012); however, the information is not recorded in a consistent fashion as is done for whales in the ENP.

Annual gray whale stranding data from Alaska to Mexico (where available) for the years 1995 to 2023 are in Table 3-4 and Figure 3-6. The number of gray whale strandings along the west coast of North America averaged 41 animals from 1995 to 1998. Stranding detection effort during these times was not directed; reports were compiled from opportunistic reports that were later relayed to NMFS' regional stranding coordinators (Gulland et al. 2005). In 1999 and 2000, gray whales stranded dead, or moribund, in unprecedented numbers from Alaska to Baja California, Mexico, with the highest numbers reported in Mexico and Alaska (Norman et al. 2000; Gulland et al. 2005). For comparison, 29 dead gray whales were found on the Alaska coast in 1989 during surveys associated with assessment of impacts caused by the *Exxon Valdez* oil spill (Loughlin 1994). The 1999 and 2000 strandings and the subsequent return to normal conditions from 2002 through 2018 are discussed in detail below. While stranding data from Mexico are not available

for every year, Martinez-Aguilar et al. (2020) reported that from one to seven gray whales have stranded in San Ignacio Lagoon annually from 2009-2019 (prior to the current UME; discussed below).

NA – not available

Sources: Gulland et al. 2005; The U.S. National Marine Mammal Stranding Data was compiled from the Marine Mammal Stranding Report – Level A data form (NOAA Form 89-864; OMB No. 0648-0178; form available at https://www.fisheries.noaa.gov/national/marine-life-distress/level-data-collection-marine-mammal-stranding-events). Level A data include details of each stranding (e.g., species, date, stranding location, carcass condition, sex, length). Details on the National Stranding Database can be found at https://www.fisheries.noaa.gov/national/marine-life-distress/national-stranding-database-public-access Details on the National Database can be found at: https://www.fisheries.noaa.gov/national/marine-life-distress/national-stranding-database-public-access. The final U.S. Marine Mammal Stranding data used in this paper were extracted from the database on 05 October 2022 and data through August 31, 2022 are included for strandings prior to the current UME.

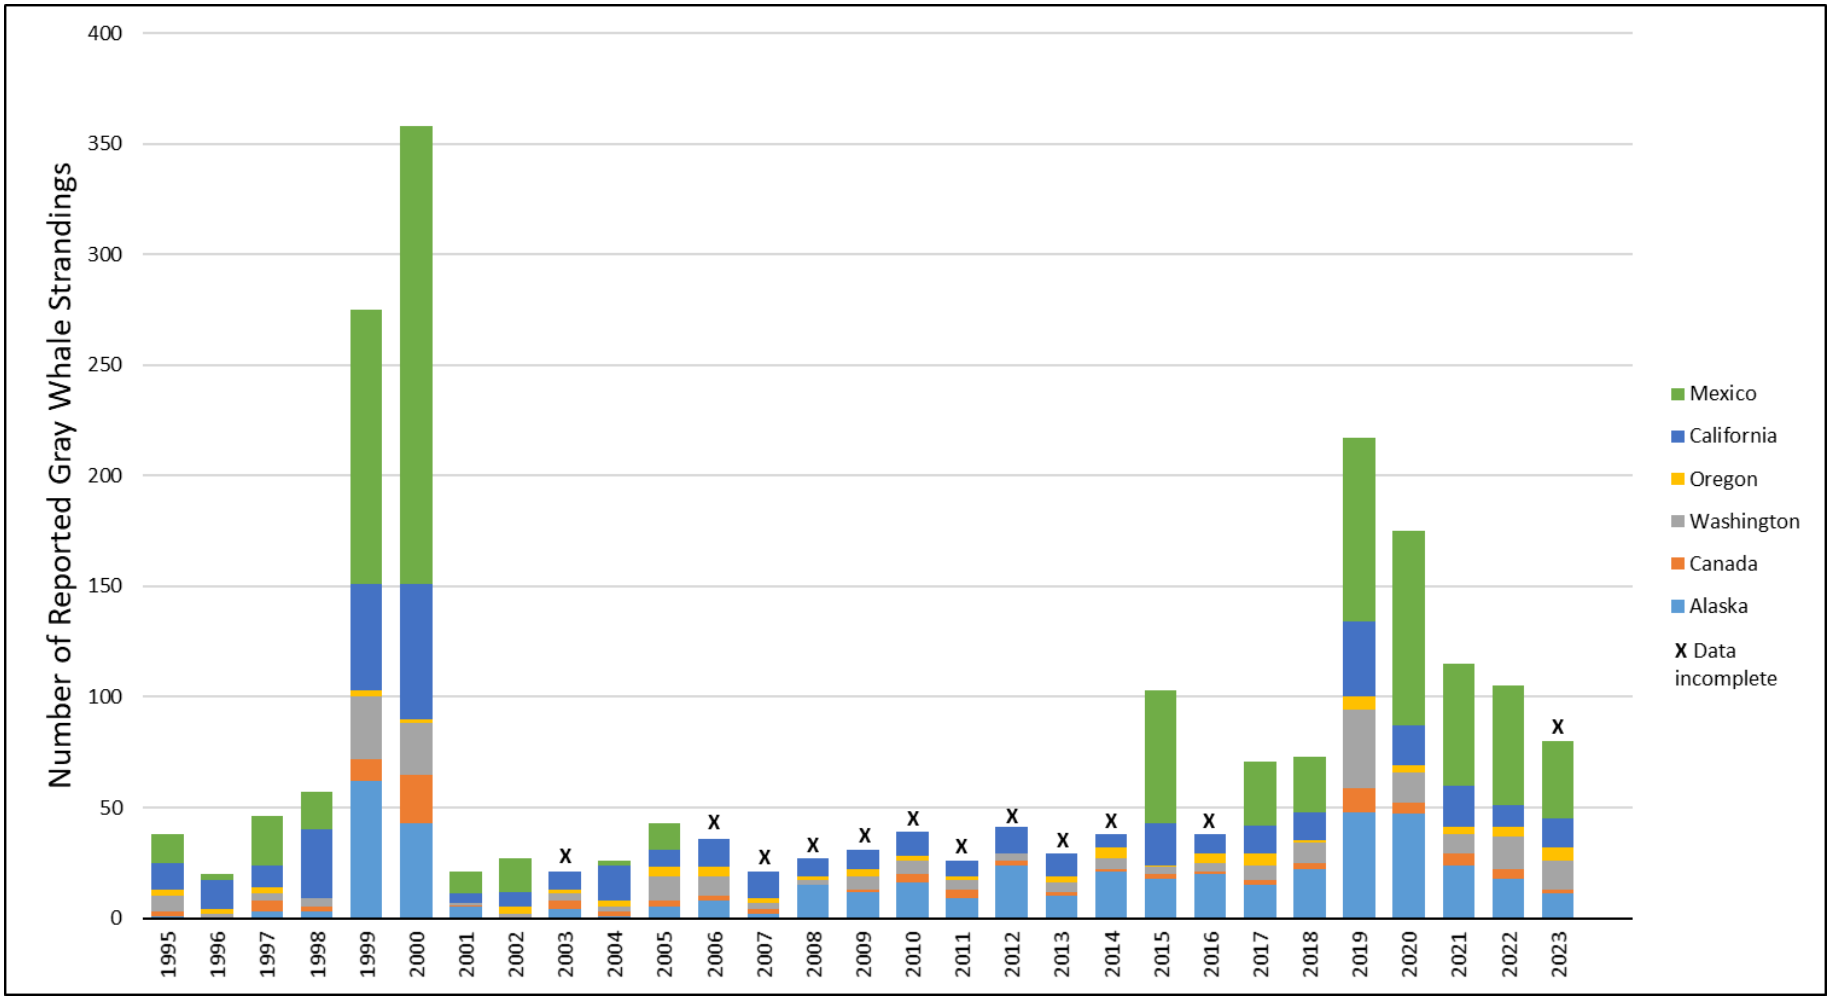

Figure 3-6. ENP gray whale strandings reported from Alaska to Mexico, 1995-2023. Years with an 'X' indicate data are incomplete; years 2003, 2006-2014, and 2016 do not have complete data from Mexico. Year 2023 shows strandings through September 26, 2023.

In 1999, the number of gray whale strandings documented along the west coast of North America increased to approximately seven times the annual mean (41) reported between 1995 and 1998 (Gulland et al. 2005; Figure 3-6). The 1992 amendment of the MMPA defines a mortality event to be "unusual" when the stranding event "is unexpected; involves significant die-off of any marine mammal population; and demands immediate response" (16 U.S.C. 1361 et seq.). Under the MMPA, the declaration of a UME authorizes a federal investigation led by the Working Group on Marine Mammal Unusual Mortality Events (referred to here as the Working Group) into the cause of the event. In July 1999, we consulted the Working Group on Marine Mammal Unusual Mortality Events (Working Group) because of the unusually high number of stranded whales (283) that year (Gulland et al. 2005). The Working Group is an advisory board created under section 404 of the MMPA and comprises 12 members with expertise in marine science, including conservation and veterinary science, who are consulted when marine mammals are dying in an unusual way.

The Working Group weighed the 1999 stranding evidence against the following seven criteria[7] developed to determine whether a stranding event is unusual:

1. A marked increase occurs in the magnitude of or a marked change in the nature of strandings when compared with prior records.
2. Animals strand at a time of the year when strandings are unusual.
3. An increase in strandings occurs in a localized area (possibly suggesting a localized problem), occurs throughout the geographical range of the species/population, or spreads geographically with time.
4. The species, age, or sex composition of the stranded animals differs from that of animals that normally strand in the area at that time of the year.
5. Stranded animals exhibit similar or unusual pathologic findings or the general physical condition (e.g., blubber thickness) of stranded animals is different from that normally seen.

[7] The criteria used to determine an unusual mortality event were updated in 2006 (71 FR 75234, December 14, 2006) to include morbidity, pathology, and population-level declines. See https://www.fisheries.noaa.gov/insight/understanding-marine-mammal-unusual-mortality-events for a list of the current criteria.

6. Mortality accompanies unusual behavior patterns observed among living individuals in the wild, such as occurrence in habitats normally avoided or abnormal patterns of swimming and diving.

7. Critically endangered species are stranding. Stranding of three or four right whales, for example, may be cause for great concern, whereas stranding of a similar number of fin whales may not.

A single criterion or a combination of criteria may indicate the occurrence of a UME.

The Working Group concluded that the 1999 stranding event was a UME because the animals were stranding throughout their range, stranding rates had increased precipitously, animal behavior and body condition were different from those reported previously (emaciated), and animals were stranding in areas where such events had not been historically noted (behavioral change) (Gulland et al. 2005). The Working Group recommended increasing evaluations and examinations of carcasses, providing a small team to summarize the available information for the Working Group, and coordinating and exchanging information between the four countries in which the gray whale stock occurs (Mexico, the United States, Canada, and Russia) (Gulland et al. 2005).

After the 1999 mortality event was declared unusual, coordination between the stranding networks increased, and two workshops were held in Mexico to enhance coordination (La Paz, March 2000 and Guerrero Negro, March 2001) (Gulland et al. 2005). Stranding detection effort varied significantly, both geographically and temporally. Because of the high stranding report rates, an increased emphasis on timely reporting started in April 1999 and continued through 2002 to allow for real-time analysis of trends (Gulland et al. 2005). We prepared a provisional report for the Working Group in 2000 (Norman et al. 2000), and preliminary findings were presented to the Scientific Committee of the IWC (Pérez-Cortés Moreno et al. 1999). In 2000, the number of stranded animals remained high, with 368 carcasses reported, representing a nine-fold increase from the 1995 to 1998 average (Gulland et al. 2005). At the annual Working Group meeting in March 2001, the Working Group recommended keeping the unusual mortality event open for monitoring, but when only 20 strandings had occurred by October 2001, they recommended closing the event (NMFS 2001b). Based on this information, we closed the event (NMFS 2001b).

We examined and synthesized stranding network information for 1999 and 2000 in Gulland et al. (2005). The authors observed that most of the strandings in 1999 and 2000 occurred in Mexican waters during the winter season. Researchers consistently surveyed stranding effort in the wintering

lagoons of Mexico, and the effort in 1999 and 2000 was comparable to that of previous years, except that records of gray whales that stranded outside their normal winter range were obtained opportunistically (Gulland et al. 2005). Increases in all regions, except Oregon, were significant. Fairly consistent stranding detection and reporting in California, Oregon, and Washington (except for remote areas of the Olympic Peninsula) took place from 1995 to 2002. Effort in British Columbia was opportunistic because of the complex coastline. Detection effort and geographic coverage in Alaska differed significantly from year to year, but dedicated surveys were conducted in some areas of the Alaska coast from 1999 to 2001 (Gulland et al. 2005).

Although each stranding was examined as thoroughly as was practical, only 3 (0.5 percent) of the 651 animals that stranded in 1999 and 2000 were examined thoroughly enough to determine the cause of death (including detection of pre-existing conditions). One whale was diagnosed with a viral infection not previously reported in stranded whales (equine encephalitis), one whale had an unusually intense infection of parasites normally associated with baleen whales, and one whale was intoxicated with domoic acid (Subsection 3.4.3.6.3, Harmful Algal Blooms). Researchers considered several factors as possible causes for the high number of gray whale strandings reported in 1999 and 2000. Factors include starvation, chemical contaminants (refer to Subsection 3.4.3.6.2, Environmental Contaminants), biotoxins (refer to Subsection 3.4.3.6.3, Harmful Algal Blooms), disease, parasites, fisheries interactions and ship strikes, variability in detection effort and reporting, and effects of winds and currents on carcass decomposition (Norman et al. 2000; Gulland et al. 2005). While the cause of the 1999-2000 UME is unkown, the emaciated condition of the stranded whales, combined with evidence of low lipid concentrations and organochlorines in the stranded animals (Krahn et al. 2001) and decreases in calf production in the population during the same time frame (Perryman et al. 2002), led many scientists to conclude that starvation was the most likely cause of mortality. Some of the animals that stranded were in good to fair nutritional condition, suggesting that not all of the strandings link logically to food resource limitation and starvation (Gulland et al. 2005).

The cause of such large-scale starvation remains unknown (Gulland et al. 2005). Some scientists think that the starvation was related to a climatically based decline in prey availability, especially related to the 1997 and 1998 El Niño events in the winter range and the Pacific Decadal Oscillation and Arctic Oscillation in the summer range (LeBouef et al. 2000; Moore et al. 2001; Moore et al. 2003). Perryman et al. (2002) also showed that seasonal changes in ice distribution in the Bering and Chukchi Seas might influence the duration of whale feeding. Because gray whales feed opportunistically on a broad suite of prey species throughout their range and move to

alternate areas when the food runs out (Subsection 3.4.3.1.4, Feeding Ecology and Role in the Marine Ecosystem), these explanations seemed simplistic (Nerini 1984; Moore et al. 2001; Moore et al. 2003; Moore 2005; Moore et al. 2007). Others postulated that the starvation related to density-dependent population effects—animals approaching carrying capacity (K) experience heightened competition for food resources and decreased reproductive success. This explanation for the starvation is imperfect, given the suddenness of the demographic change and the relatively larger numbers of adult whales that stranded (Moore et al. 2001). Gulland et al. (2005) suggested that the starvation was probably a result of both density dependence and environmental variability; populations of cetaceans that are at or near K probably are more vulnerable to environmental variability because of nutritional stress.

Weller et al. (2001) reported on the occurrence of unusually "skinny" whales in 1999 and 2000 off Sakhalin Island, Russia and suspected one or more of the following causal factors: 1) disease, 2) stress-induced metabolic shifts, 3) natural or human-produced changes in prey availability, or 4) habitat perturbation by industrial activities. Bradford et al. (2008) noted that the body condition of gray whales in the WNP varied annually and that, in the short term, these whales seem to recover from periods of compromised body condition; however, the long-term consequences are unknown. An assessment by Bradford et al. (2012) revealed that, compared to the reference year of 1997, whales in the WNP were in significantly better body condition in 2004 and in significantly worse body condition in 1999, 2006, and 2007.

Akmajian et al. (2021) used the methodology presented in Bradford et al. (2012) to assess the body condition of PCFG whales over an 18-year time span between 1996 and 2013. They found that the body condition of PCFG gray whales improved throughout the feeding season, although the rate of improvement and body condition at the start and end of the feeding season was variable by year. Local and basin-wide environmental drivers, including the Pacific Decadal Oscillation and measures of sea surface temperature and upwelling, explained some of the observed annual variability in PCFG body condition. Although the body condition of PCFG whales was lower, but not significantly so, between 1998 and 2000 when compared to their reference year of 1997. Body condition in these three years, which directly precede or include the years in which the ENP population of gray whales was undergoing a UME, was higher than in the subsequent years of 2007, 2009, and 2010, and the body condition of PCFG whales was highest in 2001, directly following the 1999/2000 UME. When compared to the data presented in Bradford et al. (2012), Akmajian et al. (2021) found that PCFG whales attained good body condition more slowly, and less predictably, than did the whales feeding in the WNP off Sakhalin

Island, likely reflecting a difference in the availability or density of prey resources on the two feeding grounds.

Using drone photogrammetry, Lemos et al. (2020) applied an index of body area to measure and compare body condition of ENP gray whales foraging off the coast of Oregon between 2016 and 2018. They found that body condition varied with age, sex, and reproductive status, with calves and pregnant females displaying the highest body condition followed by resting females, mature males, and, finally, lactating females. Body condition was significantly higher in 2016 than in 2017 and 2018, which was associated with two prior years of poor local upwelling conditions that may have caused reduced prey availability. Lemos et al. (2021) analyzed hormone levels in the feces of gray whales feeding off the Oregon coast during these same years (2016-2018) and found a significant negative correlation between body condition and the concentration of glucocorticoid metabolites. Glucocorticoid metabolite concentrations were highest in 2018, which may indicate that animals sampled in that year had endured prolonged nutritional stress.

In 2007, researchers investigating one of the main wintering lagoons in Mexico noted large numbers of whales that were "skinny" in appearance, suggesting malnourishment (Swartz et al. 2007; Urbán-Ramirez and Swartz 2007; Urbán-Ramirez et al. 2007). Photographic data collected during 2007 in Laguna San Ignacio indicated that 11 to 13 percent of the whales photographed exhibited obvious signs of malnutrition and/or disease, including noticeable depressions in the head region, sub-dermal protrusions of bony parts (e.g., the scapula), and concave rather than convex profiles of whale dorsal flank areas (Swartz et al. 2007). Urbán-Ramirez and Swartz (2007) noted other studies where some "skinny" whales that were pregnant returned to their summer feeding areas with apparently healthy calves, suggesting that "skinniness" may not be a fatal condition but instead reflect "a tolerable reduction [in] nutritional resources." Researchers have continued photographing and monitoring the condition and health of gray whales as part of the Laguna San Ignacio Ecosystem Science Program (Urbán-Ramirez et al. 2007; Urbán-Ramirez et al. 2010; Swartz et al. 2012; Rosales-Nanduca et al. 2012). More recently, drones were used to measure the body condition of gray whales in San Ignacio Lagoon, Mexico, between 2017 and 2019 (Christiansen et al. 2021). Body condition was significantly lower in 2018 versus 2017 for all reproductive classes (calves, juveniles, adults and lactating females). Torres et al. (2022) compared these images to drone images collected from whales on the PCFG feeding grounds in Oregon to evaluate variability of gray whale body condition relative to changing oceanographic conditions. The whales on the PCFG feeding ground had significantly lower body condition than did the whales in San Ignacio Lagoon. However, while the body condition of the whales

photographed in San Ignacio Lagoon declined over the time period, the body condition of the whales on the PCFG feeding ground improved over the three years of the study. The decline among whales in San Ignacio Lagoon may have been associated with the ongoing UME for ENP gray whales that began in 2019, while the increase among whales feeding off Oregon may reflect recovery from poor prey conditions during the Northeast Pacific marine heatwave that occurred from 2014 to 2016.

Following the 1999 and 2000 stranding events, stranding levels returned to the normal range, decreasing to 21 and 27 whales in 2001 and 2002, respectively, and remaining at similar levels until 2018 (Figure 3-6). Most of the dead whales that biologists examined from 2002 to 2005 died of unknown causes. In a few cases, biologists found evidence of ship strikes (propeller cuts) or entanglement in fishing gear (Gulland et al. 2005).

Elevated strandings of ENP gray whales beginning in January 2019 prompted NMFS to declare another UME for the stock on May 29, 2019 and establish a Working Group to investigate the cause of the event. NMFS assembled an independent team of scientists to coordinate with the Working Group to collect samples from the stranded whales, review the data collected, and determine the next steps for the investigation.

As of September 26, 2023, the UME declared in 2019 is ongoing with 688 gray whales stranded along the coast of Mexico, the United States, and Canada, with the greatest number of strandings concentrated in the United States and Mexico (Table 3-4). The full extent of the mortality from this event is unknown. Although some carcasses have been recovered, it is likely that many carcasses sank, washed out to sea, or stranded in remote locations and were unobserved by humans. However, it is possible to estimate mortality resulting from this UME through ongoing population surveys conducted by NMFS, and noted above in Subsection 3.2.1.2. The current UME coincides with a recent 46 percent decline in abundance observed in the 2019/2020 survey (Stewart and Weller 2021a; Eguchi et al. 2022a; Eguchi et al. 2023a).

NMFS has relied on the West Coast Marine Mammal Stranding Network for compiling reports of stranded animals, collecting data, conducting necropsies, and collecting samples from carcasses when possible in Washington, Oregon, and California. So far, full or partial necropsies have been performed on just a few of the stranded animals. Samples can be difficult or impossible to collect if the whale has become too decomposed or has stranded in an inaccessible location. NMFS does not mandate what necropsy data to collect. However, stranding network partners often record as much basic data as possible (referred to as Level A data), such as the state of decomposition and condition of the animal, the location of the

stranding, and a list of samples that were collected, if any. Some but not all of the stranded whales have shown evidence of emaciation, but more research is needed to determine the cause(s) of the UME.

It is not possible to predict how long the UME will continue. Although the population likely underwent similar events in the past, only one previous event has been designated since the 1992 amendment to the MMPA that established the UME declaration and investigation process. The 1999-2000 UME lasted for two years, after which the population recovered to its highest abundance level since monitoring began in the 1950s. NMFS regularly posts updates regarding this UME on its website at https://www.fisheries.noaa.gov/national/marine-life-distress/2019-2020-gray-whale-unusual-mortality-event-along-west-coast-and.

3.4.3.2 Western North Pacific (WNP) Gray Whales

3.4.3.2.1 WNP Seasonal Distribution, Migration, and Movements

WNP gray whales are considered to be gray whales that spend all or part of their lives in the western North Pacific in the waters of Vietnam, China, Japan, Korea (Republic of Korea and/or Democratic People's Republic of Korea), or the Russian Far East, including southern and southeastern Kamchatka but not necessarily areas north of 55° N in eastern Kamchatka (NMFS 2023c; Weller et al. 2023). This definition is consistent with that used in the IUCN/IWC Western Gray Whale Conservation Management Plan and with how the WNP gray whale subpopulation has been evaluated by the IUCN (Cooke et al. 2018).

Gray whales once were extensively distributed from the northern part of the Sea of Okhotsk to the southern tip of the Republic of Korea (Bowen 1974). They were regularly encountered in the far northeastern corner of the Sea of Okhotsk by American whalers from the 1840s to 1870s (Reeves et al. 2008). The present-day range in the WNP is believed to be considerably more restricted (Brownell et al. 2010); key summer feeding grounds include areas off northeastern Sakhalin Island and southeastern Kamchatka Peninsula, Russia (Weller et al. 2002; Weller and Brownell 2012; Tyurneva et al. 2010, 2013). In these areas, gray whales have only been observed feeding on benthic prey (especially amphipods); however, there is also speculation that they may occasionally feed on sandlance in the vicinity of Piltun Lagoon (Fadeev 2011; Vladimirov et al. 2012). Other summer feeding grounds may include areas near the Kuril and Commander Islands, off the mainland coast of Kamchatka, and in the northern Sea of Okhotsk (Brownell et al. 2010).

Whales associated with the Sakhalin feeding area can be absent for all or part of a given feeding season (Bradford et al. 2008), indicating they use other areas during the summer and fall feeding period. Some of the whales identified and feeding in the coastal waters off Sakhalin, including

reproductive females and calves, have also been documented off the southern and eastern coast of Kamchatka (Tyurneva et al. 2010). Whales observed off Sakhalin have also been sighted off the northern Kuril Islands in the eastern Okhotsk Sea and Bering Island in the western Bering Sea (Weller et al. 2013). These animals that feed in the western North Pacific, including whales found off Sakhalin and southeastern Kamchatka, represent the only large feeding concentration of gray whales in the western North Pacific, and their numbers remain small (271 to 311 age 1+ years in 2016; Cooke et al. 2017).

Little is known about the migratory routes and wintering areas of WNP gray whales, but historic evidence indicates that the coastal waters of eastern Russia, the Korean Peninsula, and Japan were part of the migratory route and that areas in the South China Sea (possibly near Hainan Island, China) and Seto Inland Sea (Japan) were used as wintering or calving grounds (Omura 1984; Weller et al. 2002; Brownell et al. 2010; Weller et al. 2012). Omura (1984) suggested that two populations of WNP whales may once have migrated to coastal waters off Japan. One population was thought to travel along the eastern (Pacific) shore of Honshu during its southbound migration to a possible calving ground in the Seto Inland Sea (Omura 1984). The other was believed to migrate along the eastern shore of Korea then across the Korea Strait to southwest Honshu and northwest Kyushu (Omura 1984). Weller et al. (2002) noted that the current WNP north-south migratory route likely includes regions off the eastern shore of Sakhalin Island in the Okhotsk Sea and along the eastern shores of mainland Russia near Peter the Great Bay and along the Korean peninsula in the Sea of Japan (Andrews 1914; Brownell and Chun 1977; Berzin 1990). However, given the absence of gray whales off the coast of Korea in recent times (i.e., since 1977), Weller and Brownell (2012) suggested that WNP gray whales have abandoned the migration corridor along the Korean Peninsula or that the gray whale subpopulation using the Korean Peninsula is extinct.

WNP gray whale sightings off both coasts of Japan are uncommon but have increased slowly in recent years. From 1955 to July 2020, only 37 records of gray whales were reported (Nakamura et al. 2022). Most of the records were from the Pacific coast of Japan with only a few (n=9) reports from the Sea of Japan. The lack of frequent sightings off Japan may reflect true absence but may also reflect limited search effort (Weller et al. 2016). While still rare, the frequency with which gray whales are reported off Japan has increased in recent years, with 16 records, some of which included the same individual, reported in 2015 or later (Nakamura et al. 2017, 2019, 2022). A female gray whale that died in a Japanese set net off the Pacific coast of Honshu, Japan in 2007 was identified as a whale observed off Sakhalin Island (Weller et al. 2008). This photographic

match was the first to show that whales on the summer feeding grounds off Sakhalin are found 1,500 km (932 mi) south within a migratory corridor. In addition, Weller et al. (2016) determined the migration of one gray whale that moved back and forth from Sakhalin Island and the Pacific coast of Honshu, Japan during 2014 to 2016. This individual was first observed as a calf with its mother off Sakhalin Island during the summer of 2014, then observed off Japan from March through May of 2015, back in Sakhalin during the summer of 2015, and then off Japan in January through February of 2016. The March to May sightings correspond with the timing of ENP gray whale northbound migrations in the spring from Mexico wintering grounds to Bering Sea feeding grounds, while the January and February sightings correspond with the timing of the ENP gray whales' southbound migrations in the winter to Mexico. These records support a migratory link between the summer Sakhalin feeding grounds and the suspected wintering area(s) somewhere off the coast of Asia (Weller et al. 2016). Data reported from the U.S. Navy Surveillance Towed Array Sensor System (SURTASS) vessel in the East China Sea would further support this migratory link, with possible gray whale acoustic signatures detected in the East China Sea from September through March in 2011 (Gagnon 2016; IUCN 2020). The 55 Hertz sweeps detected by the towed acoustic array have included up to eleven individuals in a two-hour period, moving south in the fall and north in the spring, consistent with a seasonal migration pattern (Gagnon 2016).

Very few contemporary records of gray whales in other regions of the western North Pacific exist, with only two records from Chinese waters since 1996 (Zhao 1997; Zhu 2012). The U.S. Navy SURTASS vessel recorded a unique acoustic signature in the East China Sea in 2011 that was identified as a probable gray whale (Gagnon 2016; IWC 2017; IUCN 2020). From 2011 to 2016, the Integrated Undersea Surveillance System Marine Mammal Monitoring program regularly detected acoustic signatures from gray whales in the East China Sea when a SURTASS vessel was present from September through March (Gagnon 2016). No verified records of gray whales in Korean waters have been detected since 1977 (Park 1995; Kim et al. 2013), although the possible occurrence of a gray whale in Korean waters was reported in 2015 (Kim et al. 2018).

Tagging, photo-identification, and genetic studies show that some whales identified in the WNP off Russia have been observed in the ENP, including coastal waters of Canada, the United States, and Mexico (Weller et al. 2012; Mate et al. 2015; Urbán-Ramirez et al. 2019; Martinez-Aguilar et al. 2022a). In combination, these studies have documented 60 gray whales observed in both the WNP and ENP. Despite this geographic overlap, significant mtDNA and nDNA differences are found between whales in the WNP and those summering in the ENP (LeDuc et al. 2002; Lang et

al. 2011; Carretta et al. 2023). Genetic analyses have shown that four whales sampled off Sakhalin (Russia) have identical genetic profiles (microsatellite genotypes, mtDNA haplotypes, and sex) to whales sampled on the ENP migratory route (Lang 2010; Urbán-Ramirez et al. 2019). Using photo-identification, researchers have re-sighted whales (including a few known reproductive females) from Sakhalin in the vicinity of Vancouver Island (Canada) and Lagunas Ojo de Liebre and San Ignacio (Mexico) (Weller et al. 2011; Urbán-Ramirez et al. 2012; Urbán-Ramirez et al. 2019; Martinez-Aguilar et al. 2022a). Weller et al. (2012) noted two cases in which multiple whales from the Sakhalin feeding grounds were sighted in the Pacific Northwest, suggesting that these whales may associate with one another even when using migratory routes in the ENP. These researchers also noted that these Sakhalin whales were seen in an area of the ENP (i.e., Vancouver Island) where some whales tend to linger and feed during the northbound migration (Darling et al. 1998). Weller et al. (2012) also speculated that the long distance and potential open water crossing required for transit from the ENP to the WNP may make it advantageous for whales to spend time feeding in the Pacific Northwest prior to undertaking a westerly passage to Sakhalin.

Satellite tagging studies conducted between October 2010 and October 2012 further confirm use of areas in the ENP by whales identified from the WNP (Marine Mammal Institute 2012a[8]; Mate et al. 2011; Joling 2012; Mate et al. 2015). Two whales (Russia-U.S. ID #032 and #129) tagged off Russia migrated east across the North Pacific Ocean into areas once believed to be occupied solely by ENP whales.[9] Tags from both whales transmitted data from locations in or adjacent to the coastal portion of the Makah U&A (see NMFS 2019b), Figure 3 for a map of the tracks of the two whales through the Makah U&A). The 13-year-old male (#032, Flex) (first seen as a calf near Sakhalin in 1997) was tagged on October 4, 2010, off Piltun Lagoon, northeastern Sakhalin Island (Mate et al. 2011)[10]. In mid-January 2011 (approximately 4 months after being tagged), he traveled across the Pacific Ocean to the western and central Bering Sea, then proceeded through

[8] This research was conducted by A.N. Severtsov Institute of Ecology and Evolution of the Russian Academy of Sciences (IEE RAS) and Oregon State University Marine Mammal Institute in collaboration with the U.S. National Marine Fisheries Service, Kronotsky State Nature Biosphere Reserve, and the Kamchatka Branch of the Pacific Institute of Geography. The research was contracted through the International Whaling Commission (IWC) and International Union for Conservation of Nature (IUCN) with funding from Exxon Neftegas Ltd. and Sakhalin Energy Investment Company Ltd (Marine Mammal Institute 2012a).

[9] A third gray whale (Russia/U.S. ID #141, Agent) was also tagged off Sakhalin and tracked travelling east across the north Pacific before the tag stopped transmitting in early January 2012, approximately two-thirds of the way across the Gulf of Alaska (Joling 2012).

[10] Photo-identification studies reveal that Russia/U.S. ID #032 was also assigned identification number CRC ID #1045 by Cascadia Research Collective. This whale had been sighted off Sakhalin during July-September 2007, off Vancouver Island in April 2008, and then back off Sakhalin in July 2008 (Weller et al. 2012).

the eastern Aleutian Islands and across the Gulf of Alaska to areas overlapping with ENP gray whales, heading south 12 to 16 miles (approximately 20 to 25 km) off the Washington and Oregon coasts. He was last located by satellite 12 miles (20 km) off Siletz Bay, Oregon, on February 5, 2011, which overlapped with the last few weeks of the usual ENP gray whale southbound migration through this same area (Mate et al. 2011). Although it is not known if the whale eventually traveled farther south that year, researchers noted that they saw him on several occasions while conducting research in the Sea of Okhotsk during the summer of 2012 and that he "appeared to be in good body condition and, while scarred, the tag area [had] healed" (Marine Mammal Institute 2012a).

A second gray whale (#129, Varvara), was tagged near Sakhalin Island in September 2011; she was an 8.5-year old female at the time of tagging and had been seen intermittently off Sakhalin since first sighted as a calf in 2003 (Marine Mammal Institute 2012a). Like Flex, she was tracked across the North Pacific Ocean, the Gulf of Alaska, and south along the west coasts of the U.S. and Canada. In contrast, however, Varvara's tag continued to transmit for a much longer period of time (408 days) and revealed that she spent several weeks from late January to early March along the coast of Baja Mexico, in and adjacent to the gray whale wintering lagoons. Also, her tag continued to transmit after leaving Mexico, revealing a northbound track that roughly followed the southbound track along the British Columbia, Washington, Oregon, and California coasts. Unlike her southbound migration where she transited the Gulf of Alaska, she migrated north along the coast of Alaska, crossing the Aleutian Peninsula and following the sea ice of the North Pacific Ocean and eventually entering nearshore waters off Kamchatka in late April 2012 (Journey North 2012).

Based on transmissions from Varvara received within and adjacent to the Makah U&A, researchers estimated that the whale traveled through the coastal portion of the Makah U&A southbound January 8 to 15, 2012, and northbound March 11 to 18, 2012 (Journey North 2012; Marine Mammal Institute 2012b). She eventually returned to WNP feeding grounds in the Sea of Okhotsk and the satellite tag stopped transmitting off Sakhalin Island on October 12, 2012 (Journey North 2012; Marine Mammal Institute 2012a).

Based on the best available information regarding movements of whales between the WNP and ENP, including 1) photographic records from Russian, U.S., and Mexican catalogs; 2) satellite

telemetry data; and 3) genetic analyses of biopsied whales[11], it is possible to conclude the following:

- Sixty whales known to forage in the WNP have been recorded in the ENP. Sightings include males, females, and females with calves (in Mexico lagoons).
- Sightings of several WNP whales at the same time and location along the ENP migration corridor (and within the PCFG area) indicate that some WNP whales may travel in close proximity to one another.
- The earliest and latest sightings of WNP whales in the ENP (Alaska to Mexico) indicate that such whales could be present in the PCFG range from late December until at least early May.
- The lack of WNP whale sightings between early May and late December (Weller et al. 2012; Mate et al. 2015)—a period including the most active gray whale survey months within and adjacent to the Makah U&A (Calambokidis et al. 2019; Harris et al. 2022).

These conclusions raise questions about the proportion of WNP gray whales that remain in the western North Pacific year-round. Based on population modeling that incorporated data on known movements of WNP gray whales into the eastern North Pacific, Cooke et al. (2019) concluded that 45-80 percent of Sakhalin whales migrate to the eastern North Pacific in the winter. This finding indicates that at least 20 percent, and perhaps more, of the whales migrate elsewhere, presumably to wintering areas off the Asian coast. Thus, the number of WNP gray whales remaining in the western North Pacific year-round is likely small (possibly fewer than 50 whales, Cooke 2017), making these whales more vulnerable than previously thought (Weller and Brownell 2012).

3.4.3.2.2 WNP Population Structure

Despite the observed mixing of gray whales from the WNP and ENP, significant mtDNA and nuclear genetic differences have been identified between whales feeding in the WNP near Sakhalin Island and those summering in the ENP (LeDuc et al. 2002, Meschersky et al. 2015, Brüniche-Olsen et al. 2018a, Brüniche-Olsen et al. 2021, Lang et al. 2022) and support the continued recognition of WNP whales as a distinct genetic unit. Also, while it is clear that some

[11] The genetic matches were obtained by analysing tissue biopsies from whales sampled off Sakhalin and southern California and identifying those that had identical genotypes (Lang et al. 2011). While comparison of photographs and/or genetic profiles can be used to determine if a whale has visited the WNP and the ENP, presently it is not possible to use genetic analyses alone to determine which of the animals feeding off Sakhalin remain in the WNP year-round.

whales known to feed off Sakhalin Island during the summer/fall migrate to the ENP during the winter/spring (Subsection 3.4.3.2.1 WNP Seasonal Distribution, Migration, and Movements), observations of gray whales in the WNP off Japan, Korea, and China during the winter/spring (i.e., when Flex and Varvara were seen in the ENP) suggest that not all gray whales feeding at Sakhalin Island share a common wintering ground (Weller and Brownell 2012; Weller et al. 2012).

Analysis of mtDNA control region sequences have shown differences between WNP gray whales feeding off Sakhalin and whales sampled on eastern migratory routes and/or feeding grounds (F_{ST} = 0.086-0.093, p<0.001, LeDuc et al. 2002; Lang et al. 2022); these differences remained apparent when a much longer region of mtDNA was sequenced and compared (F_{ST} = 0.124-0.202, p<0.0001, Meschersky et al. 2015; F_{ST} = 0.024, p = 0.004, Brüniche-Olsen et al. 2021). The mtDNA results support strong matrilineally driven fidelity of WNP gray whales to the Sakhalin feeding ground, whereby the return of whales first brought to Sakhalin as calves by their mothers (and, if female, the subsequent return of their calves) causes the frequencies of mtDNA haplotypes carried by reproductive females to build over time. This evidence is consistent with the patterns identified in the photo-identification data, in which the return of whales first brought to Sakhalin as calves by their mothers has been documented.

Comparisons of nuclear loci, which are bi-parentally inherited and thus reflect patterns of gene flow, also revealed statistically significant differentiation in microsatellite allele frequencies (n=12 loci) when WNP gray whales were compared with ENP gray whales feeding north of the Aleutians (F_{ST}=0.016, p=0.001, Lang et al. 2022). A subsequent study that compared WNP gray whales with gray whales sampled on the Mexican wintering lagoons also identified significant levels of nuclear genetic differentiation (F_{ST} = 0.039, p=0.001) using the panel of 84 SNP loci (Brüniche-Olsen et al. 2018a).

In addition to the significant levels of nuclear genetic differentiation identified between WNP whales and whales sampled in the ENP, the contemporary effective size of the Sakhalin gray whales was estimated to be small (80 whales, 95% CI 61.9-107.7; Lang et al. 2022). If a substantial proportion of the whales feeding off Sakhalin were breeding at random with the much larger ENP stock of gray whales, estimates of contemporary effective size, which represents the number of breeding individuals contributing to the cohorts included in the sample set (Waples et al. 2014), would be markedly higher than that calculated for the Sakhalin feeding whales. Thus the small estimate of contemporary effective size is consistent with a scenario in which Sakhalin whales are largely interbreeding with each other (Lang et al. 2022).

While highly significant, the magnitude of nuclear genetic differentiation identified between WNP and ENP gray whales is relatively low (Lang et al. 2022; Brüniche-Olsen et al. 2018b). Currently, the best available information suggests that there could be some interbreeding between ENP and WNP gray whales, which is not surprising given the observed spatial overlap between some WNP and ENP gray whales on eastern migratory routes and wintering grounds. However, paternity analysis based on 13 microsatellite loci showed that 46-53 percent of sampled whales that were first identified as calves off Sakhalin could be assigned a putative father from among Sakhalin whales (Lang et al. 2010a). When combined with the significant levels of genetic differentiation identified between ENP and WNP gray whales, these findings indicate that WNP gray whales do not mate randomly with the much larger number of whales that comprise the ENP population, but rather are largely, but not exclusively, interbreeding with each other.

Recently, NMFS convened a Status Review Team (SRT) to determine whether, under the ESA, WNP gray whales qualify as a distinct population segment (DPS) under the joint NMFS-U.S. Fish and Wildlife Service policy on identifying Distinct Population Segments ("DPS Policy," 61 FR 4722; February 7, 1996). The SRT determined that three different gray whale units meet the DPS criteria of discreteness and significance: 1) WNP-only gray whales, who spend their entire lives in the WNP, 2) WNP-ENP gray whales, who feed in the WNP in the summer and migrate to the ENP, including Mexico, during the winter, and 3) WNP-only and WNP-ENP gray whales combined (Weller et al. 2023). Ultimately, the SRT recommended that option 3, the combined unit of WNP-only and WNP-ENP gray whales, be used to designate a single DPS, given that it is not possible to readily identify individual whales as part of the WNP-only unit or the WNP-ENP unit and thus the ability to evaluate the status of each unit separately is not scientifically practicable (Weller et al. 2023).

3.4.3.2.3 WNP Abundance and Trends

The current abundance of WNP gray whales (290 whales aged 1+ with a 90% confidence interval of 271-311, Cooke et al. 2017) is markedly smaller than that of ENP gray whales (14,526 whales, Eguchi et al. 2023a). A recent assessment using a stage-structured individual-based population model estimated that the number of whales, excluding calves, using the combined Sakhalin-southeastern Kamchatka area in 2016 was 320-410 whales, with the abundance increasing at annual rates of 2-5 percent during recent years (2006 to 2016) (Cooke 2018a). Approximately 130-170 of those whales were estimated to feed predominantly off Sakhalin Island (Cooke et al. 2017). Based on the positive growth rates and estimates that the number of mature WNP gray

whales now is greater than 50, the IUCN downlisted the WNP gray whale from Critically Endangered to Endangered status in 2018 (Cooke et al. 2018).

Before commercial whaling, at least 1,500 whales were thought to be part of the WNP population (Yablokov and Bogoslovskaya, 1984). While it is likely that the number of WNP gray whales before exploitation was smaller than the number of ENP gray whales, WNP gray whales did comprise a more significant portion of the species in the North Pacific in the past. Historical assessments by Yablokov and Bogoslovskaya (1984) and Berzin and Vladimirov (1981) suggest that as many as 10,000 WNP gray whales (pre-exploitation) may have dwindled to as few as 1,000 animals by 1910. Other assessments suggest the population could have been as high as 25,000 before commercial whaling (Cooke et al. 2019). By the 1970s, the population was considered extinct because it either was extinct or so low in abundance that whales were not observed (Bowen 1974). Mark-recapture analysis of photo-identification data collected on the Sakhalin Island feeding ground provided the first post-exploitation estimates of the abundance of WNP gray whales. It indicated that fewer than 100 whales used the feeding ground between 1997 and 2003 (Bradford et al. 2008).

3.4.3.2.4 WNP Status, Carrying Capacity, and Related Estimates

The WNP stock is currently listed as endangered under the U.S. Endangered Species Act and depleted under the MMPA. In response to a NMFS Task Force recommendation (Weller et al. 2013)[12], NMFS first released a draft stock assessment report for the WNP stock of gray whales in January 2015 (Carretta et al. 2015). As noted in the subsection above, the current population estimate for this stock is 290 non-calf animals, while the minimum population estimate (lower 5th percentile) is 271 animals (Cooke et al. 2017; Carretta et al. 2023). The stock assessment report does not address the carrying capacity for this stock, but the analysis by Moore and Weller (2013) results in PBR values ranging from 0.07 whales (using a recovery factor of 0.1) to 0.33 whales (using a recovery factor of 0.5), with uncertainty in these values being driven by uncertainty in the fraction of WNP animals migrating in ENP areas.

The IWC has not established a catch limit for WNP gray whales. In 2018, the IWC's Scientific Committee reviewed the analytical framework and management advice supporting the allocation of gray whale catch limits to aboriginal hunters (IWC 2018a). The Committee noted that the

[12] The recommendation was made in light of the MMPA's requirement that SARs be published for all stocks of marine mammals in U.S. waters in combination with the recent evidence that some whales identified in the WNP have been observed to migrate through U.S. waters to Mexico.

existing framework was designed to evaluate ENP gray whales but does not incorporate conservation considerations for WNP whales.

The limited sighting data available on WNP migrations and movements suggest that it is most likely that whales from this stock could be encountered in the vicinity of the Makah U&A during the hunting season proposed by the Tribe, perhaps with the exception of early May to late December. The IWC and a series of independent expert panels established by the IUCN have emphasized the urgent need for a comprehensive international strategy to eliminate or mitigate anthropogenic threats facing WNP gray whales throughout their range. The international Western Gray Whale Rangewide Workshop, convened by IUCN in Tokyo in 2008, summarized the state of knowledge regarding the population, identified information gaps, specified and ranked threats, and mapped out needed research and management actions. Its primary recommendation was to develop and implement a conservation plan for WNP gray whales, a draft of which was completed in August 2010 (Brownell et al. 2010) and the subject of a memorandum of cooperation signed by the U.S., the Russian Federation, and Japan (Memorandum of Cooperation 2014). In 2016, the memorandum was signed by Mexico and the Republic of Korea (IWC 2019a).

In 2023, NMFS published an ESA 5-year review summarizing population trends and threats to the WNP gray whale DPS (NMFS 2023c). Although the DPS has grown slowly over the past several decades, the population size remains small, in particular reproductive females, and thus remains highly vulnerable to extinction; as such, the SRT recommended that the WNP gray whale DPS remain listed as endangered (NMFS 2023c). Primary threats to the population include oil and gas exploration and fisheries bycatch and entanglement, although a wide range of threats, or potential threats, were analyzed including UMEs, disease, killer whale predation, scientific use, whale watching, commercial and subsistence harvest, and inadequacy of existing regulatory mechanisms (NMFS 2023c).

3.4.3.3 Eastern North Pacific (ENP) Gray Whales

3.4.3.3.1 ENP Population Structure

As noted previously, ENP gray whales are managed as a single stock by NMFS (Carretta et al. 2023) and the IWC (2022a) and are recognized as a separate subpopulation by the IUCN (Cooke 2018b) (see also Subsection 3.4.3.2.2, WNP Population Structure). There has been longstanding recognition that ENP and WNP gray whales are separate stocks (Rice and Wolman 1971), and genetic studies support this distinction (LeDuc et al. 2002; Lang et al. 2010; Lang et al. 2011; Meschersky et al. 2012; Lang et al. 2022). There is also some speculation that recently detected mixing between the WNP and ENP (refer to Subsection 3.4.3.2.1, WNP Seasonal Distribution,

Migration, and Movements) signifies a lack of gray whale population structure (Bickham et al. 2013). There is also evidence from a variety of sources (genetic, photographic, and telemetric) indicating possible substructure within the ENP population, in particular the possible existence of a PCFG stock of gray whales (Frasier et al. 2011; IWC 2011a; Weller et al. 2013; Lang et al. 2014). Subsection 3.4.3.4, Pacific Coast Feeding Group (PCFG) of Gray Whales discusses this evidence in detail.

Alter et al. (2012) investigated the pre-whaling diversity, population dynamics, and feeding ecology of gray whales using genetic and isotope analyses to compare modern gray whale samples to those from 150 to 3,500-year-old gray whale bones excavated from archaeological sites on and near the Makah reservation. Overall, their genetic analysis supported the hypothesis that gray whales experienced a recent major population decline. Results from their isotope analysis showed very slight differences between ancient and modern whale samples, suggesting the possibility of population substructure in the past in the vicinity of the Olympic Peninsula and Vancouver Island.

Genetic studies also suggest some substructuring may occur on the wintering grounds, with significant differences in mtDNA found between females (mothers with calves) using two of the primary calving lagoons and females sampled in other areas (Goerlitz et al. 2003). Other research, employing both mtDNA and microsatellites, identified significant departure from panmixia (random mating) between two of the lagoons using nuclear data, although no significant differences using mtDNA were observed (Alter et al. 2009).

The IWC Scientific Committee has conducted a series of annual (2014-2018) rangewide workshops on the status of North Pacific gray whales. The primary objective was not to determine a single 'best' stock structure hypothesis (unless definitively supported by existing data) but rather to identify plausible hypotheses consistent with the suite of available data. The goal is to create a foundation for developing range-wide conservation advice. The primary hypotheses deemed as most plausible considered three separate 'breeding stocks' or biological populations. Currently, the IWC recognizes two 'high priority' hypotheses for inclusion in the stock status modelling framework: (a) "Hypothesis 4a" which assumes that two breeding stocks exist and overwinter off Mexico, and (b) "Hypothesis 7a" which is characterized by maternal feeding ground fidelity, two migratory routes/wintering grounds used by Sakhalin whales, and non-random mating.

Under Hypothesis 4a, one breeding stock includes Northern Feeding Group (NFG) and PCFG whales, and the second breeding stock includes Western Feeding Group (WFG) whales that mate

largely with each other while migrating to Mexico. Whales show matrilineal fidelity to feeding grounds, one migratory route/wintering region used by Sakhalin whales, and non-random mating. Areas off Southern Kamchatka and the Northern Kuril Islands are used by some whales that belong to the breeding stock comprised of WFG whales and some whales that belong to the NFG. Although a third breeding stock (the western breeding stock) may once have existed, it is assumed to have been extirpated under Hypothesis 4a.

In comparison, Hypothesis 7a assumes that three breeding stocks exist: an Eastern Breeding Stock (EBS), a Western Breeding Stock (WBS), and an unnamed stock of WFG whales that largely breed with each other while on migration to Mexico. The EBS includes two feeding groups: PCFG and NFG. The WBS whales feed in the Northeastern Sakhalin Island sub-area, areas of the Okhotsk Sea, and the Southern Kamchakta and Northern Kuril Islands and then migrate to Vietnam-South China Sea sub-area to overwinter. Southern Kamchatka and the Northern Kuril Islands are used by the WFG (that are part of the unnamed breeding stock migrating to Mexico), the NFG, and the feeding whales that are part of the WBS (IWC 2021a).

Sex Ratio of ENP Whales

Lang et al. (2014) conducted genetic analyses on dozens of gray whale samples from the ENP, including whales from off Chukotka and from the PCFG. Females made up 59 percent of the whales sampled from the northern stratum (collected from whales north of the Aleutians). This same level of female bias was also found in the samples taken from off Chukotka and from the PCFG.

3.4.3.3.2 ENP Seasonal Distribution, Migration, and Movements

ENP gray whales generally migrate seasonally along the coast of North America between a summer range as far north as the Bering, Chukchi, and Beaufort Seas and a winter range as far south as the Baja California Peninsula and Gulf of California in northwestern Mexico (Rice et al. 1984; Urbán-Ramírez et al. 2003) (Figure 3-3). The general characteristics, timing, and migratory distance relative to shore for fall/winter southward and spring northward migrations are described more specifically below. In addition, while most ENP whales migrate north of the Aleutian Islands/Alaska Peninsula, a small number of whales remain south of the Alaska Peninsula to feed. The IWC refers to the southern assemblage of ENP whales observed between June 1 and November 30 from 41° N to 52° N in 2 or more years as the "Pacific Coast Feeding Group" (PCFG) (IWC 2012a). In addition to these PCFG whales, there are also 'straggler' or 'transient' gray whales (IWC 2012e; Calambokidis et al. 2014) that have only been seen feeding in the PCFG area in a single year (presumably using northern feeding grounds in other years). This

FEIS discusses whales seen in the PCFG area separately in Subsection 3.4.3.4, Pacific Coast Feeding Group (PCFG) of Gray Whales. The remainder of this subsection focuses on the larger group of ENP whales that migrate to summer/fall feeding areas north of areas used by the PCFG (i.e., north of 52° N, roughly northern Vancouver Island).

Summer/Fall Foraging

The bulk of the ENP population forages in a summer/fall range north of the Aleutian Islands in areas commonly referred to in the literature as the northern seas (Nerini 1984; Gardner and Chávez-Rosales 2000) and primary, principal, traditional, northern, or summer feeding grounds (e.g., Braham 1984; Nerini 1984; Swartz 1986; Darling et al. 1998; Moore et al. 2000; Dunham and Duffus 2002; Findlay and Vidal 2002). In addition, sizeable aggregations of gray whales (up to 400 animals) have been reported during the late spring and summer off southeast Alaska, especially near Kodiak Island (Moore et al. 2007; Gosho et al. 2011). These sightings are north of the PCFG's defined range and south of the primary summer range used by most ENP whales. Little is known about these southeast Alaska whales except that there appears to be some consistency in their occurrence and some have been sighted further south in the PCFG area (Moore et al. 2007; Gosho et al. 2011). The discussion that follows focuses on the northern foraging areas used by the vast majority of the ENP population.

The bulk of the ENP herd usually arrives in the Bering Strait by the end of May (Yablokov and Bogoslovskaya 1984). Hessing (1981) observed approximately 4,000 gray whales transiting the Aleutian Islands via Unimak Pass from May through mid-June (peaking on June 4), and Barrett-Lennard et al. (2011) reported sightings in this area during the month of May. The extent of ENP gray whale distribution and habitat use in the summer range is not well documented, and patterns are difficult to discern; much of the data come from historical whaling records or observational efforts that are not consistent or comparable (Berzin 1984; Clarke and Moore 2002). Sighting data from Soviets and Americans throughout 1958 to 1993 are summarized in Clarke and Moore (2002), but the information is of limited value because of the inconsistent methods by which the data were collected. Generally speaking, whales are distributed as far east as the Canadian Beaufort Sea (Rugh and Fraker 1981), as far west as the Eastern Siberian Sea along the coastal shelf of Siberia and near Wrangel Island (Berzin 1984; Reilly 1984; Miller et al. 1985; IWC 2006), along the north and south coasts of the Chukotkan Peninsula (Berzin 1984; Miller et al. 1985), at shoals in the northeastern Chukchi Sea near Barrow, Alaska (Moore et al. 2000), and in the northern Bering and southern Chukchi Seas in areas between the Bering Strait and St. Lawrence Island (Moore et al. 2003).

Sea ice cover influences gray whale distribution, especially during long periods of time, such as glacial advances during the Pleistocene, when global climate change likely eliminated major feeding areas (Pyenson and Lindberg 2011). However, the primary factor influencing distribution and habitat selection appears to be availability of prey (Moore 2000; Clarke and Moore 2002). During the summer months in the Alaska Beaufort Sea (i.e., western Beaufort Sea) and southern Chukchi Sea, gray whales selected coastal and shoal habitats (less than 115 feet [35 m] deep) with less than 20 percent ice cover (Moore et al. 2000). Scientists at the 2006 IWC meeting reported that six satellite-tagged individual whales were also monitored moving north to these regions in open ice leads (i.e., open water paths in the ice) during mid-June, but they moved through areas that had 30 to 40 percent ice cover at times (IWC 2006). In the fall months, whales have been observed feeding in more than 70 percent ice cover. Moore et al. (2000) concluded that gray whale habitat selection is not strongly related to ice conditions (ratios for numbers of whales at various depths were similar for both light and heavy ice years); instead, gray whale distribution is primarily linked to prey density. During years when strong surface winds result in the cross-shelf transport of upwelled, nutrient-rich waters, benthic prey species are probably more productive and densely aggregated in nearshore coastal and shoal habitats (Moore 2000). During years of moderate to low wind mixing and transport, gray whales select shelf and trough habitats further offshore, where currents are directed by bathymetric features (i.e., seafloor geology) and may provide migration cues to southbound whales (Moore et al. 2000). Perryman et al. (2011) observed that ice cover has not decreased consistently across seasons and that during the past 30 years, the earliest northbound migrants (pregnant females) are encountering ice distributions that have changed relatively little during that period.

The overall abundance of the gray whale population also probably influences distribution in the northern portion of the summer range (and elsewhere) because, as the gray whale population increases, the range may expand as individuals forage more widely for limited food resources (Moore et al. 2007). Rugh et al. (2001) proposed that the week's delay in southward migration timing after 1980 may have been due to a wider distribution of the population as their search for food covered increasingly greater areas, making the trip south longer. This effect of a larger population leading to a wider dispersal was also noted by other authors (Yablokov and Bogoslovskaya 1984; Stoker 2001).

Within-season movement of gray whales has been documented over the years, leading researchers to the conclusion that whales in the northern portion of the summer range exhibit constant and extensive local migrations between feeding areas; they do not stay in one area for

the entire season (Yablokov and Bogoslovskaya 1984; IWC 2006). Individual whale movement in the northern portion of the summer range has not been documented to the extent of individual whales in the southern portion of the summer range (photographic-identification is impractical in such a large and remote area), but scientists at the 2006 IWC meeting reported preliminary results from a satellite-tagging study. The tagging data show that four individual whales used the southern Chukchi Sea for more than 3 months, with the distribution of the individual whales overlapping by only 3 percent within this area (IWC 2006). In concluding its 2011 Implementation Review of gray whales, the Scientific Committee of the IWC noted that further work should be undertaken to investigate the possibility of population structure on the northern feeding grounds, especially in the region of the Chukotkan hunts (IWC 2011a). To that end, the Scientific Committee of the IWC held the first of at least two workshops to explore the most recent data and analyses available regarding North Pacific gray whale movements and stock structure (IWC 2014b; refer to Subsection 3.4.3.1.2, Global Distribution and Population Structure). Rangewide workshops were also held in 2017 (IWC 2017) and 2018 (IWC 2019b), and a recent paper documented some fine-scale site fidelity in northern feeding grounds (Filatova et al. 2022).

Long-term shifts in the summer range have also been described recently and are thought to be related to the operation of two major oceanic climate cycles: the Arctic Oscillation and the Pacific Decadal Oscillation. These two cycles generally occur in the North Pacific every 10 to 30 years, last 30 to 40 years, and have distinct warm and cool phases caused by changes in sea surface pressure and sea surface temperature. The operation of both the Arctic Oscillation and Pacific Decadal Oscillation appears to be causing a major ecosystem shift in the Bering Sea, a transitional area that is at a crossroads between the Pacific Ocean and the Arctic Ocean and is, therefore, influenced by both cycles (Bond 2006; Grebmeier et al. 2006).

The Bering Sea (northern Bering and southern Chukchi Sea) was once considered the primary gray whale feeding ground (Braham 1984; Moore et al. 1986; Kim and Oliver 1989; Moore et al. 2000). During the late 1970s to early 1980s, it was characterized by cold climate conditions with extensive seasonal ice cover and high benthic productivity (Grebmeier et al. 2006). Time-series studies from the Chirikov Basin (between St. Lawrence Island and the Bering Strait) show that in 1980, *Ampeliscid* amphipods were the primary prey items of gray whales, sampled at record-high densities from the 1970s to mid-1980s (Stoker 1981; Yabolokov and Bogoslovskaya 1984; Grebmeier et al. 1989; Highsmith and Coyle 1990). The amphipod prey base declined by 30 percent between 1986 and 1988 (Highsmith and Coyle 1992; Sirenko and Koltun 1992). This

reported decline in benthic biomass did not have an immediate observable effect on gray whale abundance. A subsequent gray whale mortality event in 1999/2000, coupled with observations of emaciated whales, led scientists to conduct aerial surveys of the Chirikov Basin in 2002 to compare distribution and relative abundance with the 1980s data (Moore et al. 2003). Sighting rates of gray whales in the Chirikov Basin were 3 to 17 times lower than they had been in the 1980s (Moore et al. 2003; Grebmeier et al. 2006). Benthic productivity of the prey base had declined precipitously, and only the southern Chukchi Sea supported dense aggregations of whales (Moore et al. 2007).

The Bering Sea is now characterized by warmer conditions with less sea ice cover and lower benthic productivity than in the 1970s (Grebmeier et al. 2006). Gray whales have responded by foraging in other areas (Moore et al. 2003; Moore 2005; Moore et al. 2007). Observers are now seeing larger feeding aggregations in different parts of the northern portion of the summer range, north of the Bering Strait in the south-central Chukchi Sea and just north of St. Lawrence Island in the northern Bering Sea (south of the Chirikov Basin), an area that was previously recorded as devoid of gray whale feeding (Clarke and Moore 2002; Moore et al. 2003). Scientists reported at the 2006 IWC Scientific Committee meeting that a large proportion of 17 satellite-tagged whales fed extensively in the Chukchi Sea; six whales retained their tags for more than 100 days, and all six spent most of their time in the Chukchi Sea (IWC 2006). Stafford et al. (2007) noted that gray whales were once rare visitors to the Beaufort Sea but their numbers have been increasing since the mid-1990s. In 2003/2004, these researchers deployed acoustic recorders in the Beaufort Sea and unexpectedly detected gray whale calls throughout the winter near Barrow, Alaska. Additional analysis revealed that there was sufficient ice-free space for gray whales to surface and breathe, so it is unlikely that calls came from animals that were entrapped in the ice (Stafford et al. 2007). These studies support the possibility that gray whales are altering their foraging habits in the Arctic. Observers have also documented feeding that has not been seen previously in the southern portion of the summer range, such as near Kodiak Island and in the Gulf of Alaska (near Sitka) (Moore et al. 2003, 2007; Gosho et al. 2011).

Fall/Winter Southward Migration

The onset of the southward migration is difficult to define (Rugh et al. 2001) and is typically associated with the primary breeding period. Timing may be influenced by several environmental variables, including the extent of ice coverage, availability of food resources, and photoperiod (Rugh et al. 2001; Clarke and Moore 2002; Swartz et al. 2006). It is also related to how widely the whales are distributed for foraging (Rugh et al. 2001). Most whales migrate out of northern seas

sometime around mid-October to November, but some have been seen swimming south near Point Barrow as early as mid-August, and some have been seen along the Chukotkan Peninsula as late as mid-December (Rugh et al. 2001). The southward migration is generally grouped into two phases by age, sex, and reproductive status (Rice and Wolman 1971). The first migrant phase consists of near-term pregnant females, followed by non-pregnant females and mature males. The second migrant phase consists of immature whales of both sexes (Swartz et al. 2000; Swartz et al. 2006). Poor weather conditions and widely scattered offshore distribution of gray whales make it difficult to survey whales migrating through the area (Green et al. 1995; Shelden et al. 2000; Rugh et al. 2001), but some studies are available. Shelden et al. (2000) reported observations of gray whales off the coast of Washington and in the Strait of Juan de Fuca near Port Angeles in early to mid-November. Observational studies also support the presence of southbound gray whales off the coast of Washington in December (Pike 1962; Darling 1984; Shelden et al. 2000; Calambokidis et al. 2009a) and January (Calambokidis et al. 2009a). Using data from surveys at other locations, along with measured travel speeds of migrating gray whales, Rugh et al. (2001) calculated January 5 as the peak of the southward migration past Tatoosh Island.

The most routine observations of the gray whale migration have been in California (Rugh et al. 2001). Data from shore-based stations have shown a 1-week shift in timing of median dates of southbound migrants (from January 8 to January 16) after 1980. This might have been due to an oceanographic regime shift in the northern portion of the summer range. The shift caused extreme ice retreats and may have expanded the distribution of gray whales on the feeding grounds and increased the distance of the southward migration (Miller et al. 1994; Hare and Mantua 2000; Rugh et al. 2001; Moore et al. 2003; Shelden et al. 2004; Moore 2005). Concurrent with these findings, southbound calf sightings have increased near San Diego (southern California) and Carmel (central California) since 1980; the 1-week delay in the southward migration has meant that calving has occurred farther north than the Baja lagoons during the southward migration (Shelden et al. 2004). Gray whales generally reach these wintering grounds starting in late December or early January and reach maximum densities in February. There is also recent evidence that not all gray whales migrate south for the winter. Mate et al. (2010) satellite tagged a whale that remained off the northern California and southern Oregon coasts throughout the winter.

Winter Breeding and Calving

Gray whales occupy a large winter range, extending along the west coast as far north as Point Conception and the Channel Islands in central California (near Santa Barbara) and south to Cabo

San Lucas (Reilly 1984; Jones and Swartz 2002; Urbán-Ramírez et al. 2003), where most investigators have concentrated their observations (Findlay and Vidal 2002). Findlay and Vidal (2002) also reported that some of the population migrates farther south, around the tip of the peninsula and into the Gulf of California. A few isolated sightings of gray whales over the years have also occurred in more southern localities along the Pacific coast of mainland Mexico and at the oceanic Revillagigedo Islands (Findlay and Vidal 2002). In contrast, there is evidence that some whales do not migrate as far south as Mexico (Herzig and Mate 1984; Swartz 1986; Swartz et al. 2006), and Shelden et al. (2004) hypothesized that females that give birth north of Mexico may instead congregate near California's Channel Islands until their calves are large enough to migrate north.

As in the summer range, gray whales in the winter range often aggregate in specific areas of the ocean, particularly near and within coastal lagoons and bays of Baja, including Lagunas Guerrero Negro, Ojo de Liebre (Scammon's Lagoon), San Ignacio, Bahia Magdalena, Bahia Almejas, and Santo Domingo Channel (Urbán-Ramírez et al. 2003). The whales segregate spatially and temporally, such that their distribution, gross movements, and timetable of lagoon occupation differ for each age-sex group (Jones and Swartz 1984; Urbán-Ramírez et al. 2003; Swartz et al. 2006). Females with calves concentrate within the interiors of lagoons or lagoon nurseries and shift to the lagoon inlets and coastal waters occupied by the single whales without calves (i.e., oestrus females and mature males) when those whales depart for the northward migration (Jones and Swartz 1984; Swartz et al. 2006). Although there is repeated use of some lagoons, whales move among and between lagoons and spend some amount of the winter in waters outside of lagoons (Urbán-Ramírez et al. 2003). Recent surveys indicate that more females are using Laguna San Ignacio as a winter aggregation area and that mother-calf pairs from other such areas are moving into this lagoon late in the winter breeding season, a pattern last seen in the late 70s and early 80s (Swartz et al. 2012).

The aggregating behavior of the whales and their within-season movement between different areas on the wintering grounds relate to both reproductive and feeding activities, although some literature reports that whales mostly fast throughout the winter and rely on reserves of body fat to carry them through the winter period. Most of the feeding in the wintering grounds appears to be pelagic, rather than benthic, although researchers have seen mud plumes indicative of benthic feeding (Nerini 1984). Pelagic prey species include sardines, bait fish, spawning squid, and crustaceans associated with eel grass mats (Nerini 1984). Feeding areas that foraging gray whales frequent, as documented by Nerini (1984), include San Ignacio Lagoon, Magdalena Bay, Punta

San Juanico, and Laguna de San Quentin in Baja Mexico, and La Jolla and Point Loma, California.

On a longer-term basis, evidence indicates that distribution and habitat use within the wintering range varies according to environmental conditions. As one example, Bryant et al. (1984) observed that whales apparently deserted the Laguna Guerrero Negro, the northernmost lagoon, during the late 1960s but reestablished during the 1970s, increasing steadily until an observed decline in 1982. They postulated that the whales recolonized the area after commercial shipping and dredging activities stopped in 1967, but they also noted that year-to-year fluctuations in relative abundance had previously been reported and observed that some individual whales enter lagoons in successive years whereas others return after longer intervals.

Recent studies have attributed shifts in the winter range to the El Niño Southern Oscillation, a multi-year climatic cycle occurring irregularly in the tropical Pacific every 2 to 7 years and lasting 6 to 18 months. When El Niño events occur, driven by low atmospheric pressure between Tahiti and Australia, sea surface temperatures warm and biological productivity drops near Baja. Whales shift farther north in their distribution, such as during the 1998 wintering season. When El Niños subside (and La Niñas occur), the sea surface temperatures are cooler near Baja (e.g., the 1989 and 1999 calving seasons), the biological productivity is higher, and whales shift south in their distribution (Gardner and Chávez-Rosales 2000; Sánchez-Pacheco et al. 2001; Urbán-Ramírez et al. 2003; Swartz et al. 2012). The observation of this shift led Gardner and Chávez-Rosales (2000) to conclude that environmental conditions may be more important factors in determining breeding locations than site fidelity.

Spring Northward Migration

In mid-February, as the southward migration comes to an end in California and Mexico, the northward migration begins. This overlap suggests that not all of the gray whale population winters near the Baja California Peninsula. Some whales may only go as far south as the coastal waters of California before they turn around to head north (Herzig and Mate 1984; Swartz 1986; Swartz et al. 2006; Mate et al. 2010). The northward migration to summer feeding areas occurs in two generally grouped phases according to age, sex, and reproductive condition (Poole 1984; Swartz 1986; Swartz et al. 2006). The first migrating phase occurs from mid- to late-February and comprises newly pregnant females, followed by adult males and non-pregnant females two weeks later, and lastly by immature whales of both sexes another week later (Swartz et al. 2006). As this first phase of the migration is underway, mothers with newborn calves move from interior lagoons to lagoon inlets and coastal waters previously occupied by the single whales (Swartz et al. 2006). These

mother and calf pairs compose the second migrating phase of whales and are the last to leave the wintering areas, departing between late March and May and generally arriving in their summer feeding range from May to June (Swartz et al. 2000; Swartz et al. 2006).

Poole (1984) reported the first phase of northbound migrants off the coast of central California from early February to early April. Gilmore (1960) reported similar dates (mid-February, peaking in March and April, and tapering off in early May) as whales pass San Diego. Herzig and Mate (1984) reported the first phase of northbound migrants passing through the waters off Oregon in mid-February through April, peaking in mid-March. Wilke and Fiscus (1961) observed over 200 gray whales (singles, pairs, and groups of 3 to 4 animals) off the central Washington coast on April 24 and 25, 1959. Similarly, Calambokidis et al. (2009a) sighted northbound gray whales along the central Washington coast (offshore of Grays Harbor) during February, March, and April. A study conducted at Unimak Pass, Alaska, reported a peak passage of northbound phase-one migrants in the last week of April, indicating an approximate lag of 4 to 5 weeks between Oregon and Alaska (Hessing 1981; Herzig and Mate 1984).

The mother-calf migrants in the second migrating phase travel more slowly than the whales in the first migrating phase to accommodate nursing and calves (NMFS 2001a), and they have been reported to follow the first phase by 7 to 9 weeks (Herzig and Mate 1984). The predominantly mother-calf pair migrants in the second phase of the northward migration have been sighted passing through the waters off central California from early April to late May (Poole 1984; Perryman et al. 2011) and passing by Oregon from late April to May, peaking in mid-May (Herzig and Mate 1984). During the Tribe's 2000 hunt in coastal waters of their U&A, Gearin and Gosho (2000) noted that most of the whales observed during the hunt (April 17 to May 29) were large individual whales and not pairs. Whales observed in the vicinity of the hunt did not appear to be milling or feeding but instead exhibited migratory behavior in terms of their dive duration and movements. Further north, Hessing (1981) observed mother-calf pairs passing Unimak Pass, Alaska, from May through mid-June, peaking on June 4.

Taking both migration phases into account, northbound whales of all ages and both sexes are present off the Washington coast from late February through June. There are no direct observations that establish the timing of either phase of the northward gray whale migration through the action area, nor are there any published estimates based on observations from other areas (as Rugh et al. [2001] calculated for the southward migration). Given the available observational data, it is reasonable to estimate that migrants in the first phase of the northward

migration would be in the action area from March through early May, and migrants in the second phase would be in the action area from roughly early May until June.

Migratory Distribution Relative to Shore

The migratory distribution of gray whales relative to shore (i.e., location, width, and extent of the migratory corridor) varies based on environmental conditions (such as bottom topography, climate, and water depth), migration season and phase, and use of the migratory corridor (such as feeding, breeding, or migrating). Generally, gray whales migrate closer to shore where the continental shelf is narrow, such as near Granite Canyon, California, and distribute farther offshore where the continental shelf is broader, such as near the Channel Islands, California (Shelden et al. 2004). There is also evidence that northbound whales travel closer to shore during spring than do southbound whales in fall and winter (Herzig and Mate 1984; Green et al. 1995; Calambokidis et al. 2009a). During the 1999 and 2000 Makah hunts (in April and May), gray whales were sighted or pursued an average of 1.0 mile (1.6 km) from shore (Gosho 1999; Gearin and Gosho 2000).

Off the coast of Oregon, where the continental shelf is relatively narrow, Herzig and Mate (1984) systematically documented the offshore distribution of both northward and southward migrations, including both phases of migrants, from November to May, 1978 to 1981. They determined that more than 50 percent of all whales in the first phase of the southward and northward migration passed between 1 and 2 miles (1.6 and 3.2 km) from shore in depths of 131 to 197 feet (40 to 60 meters). They also estimated that 90 percent of the second phase of northbound migrants, consisting predominantly of mother-calf pairs, passed less than 2,625 feet (800 m) from shore. Herzig and Mate (1984) noted that, as the northward migration progressed, pod size decreased and whales moved progressively closer to shore, traveling within 1 mile (1.6 km) from shore. Green et al. (1992) evaluated sightings data relative to depth and distance to shore and concluded that the gray whale migration corridor does change in concert with varying depths (i.e., whales were found greater distances offshore when shallow depths extend further offshore).

These nearshore patterns of migration for northbound whales are consistent with observations made off the coast of California from 1980 to 1982 (Poole 1984). Poole (1984) determined that the first phase of northbound migrants moved slightly farther offshore than the second phase; the first phase traveled within a straight-line corridor from one major point of land to another to avoid bights in the coastline, while the second phase (consisting of 90 percent mother-calf pairs) hugged the contours of the coastline. Sixty percent of the first phase of northbound migrants passed between 2 miles and 0.5 mile from shore (between 3.2 km and 800 m), 20 percent between

0.5 mile and 0.1 mile from shore (between 800 m and 200 m), and 13 percent within 0.1 mile (200 m) of shore. Ninety-nine percent of the second phase of northbound migrants passed within 0.1 mile of shore in 1980, and 96 percent passed within that distance in 1981. Poole (1984) and Braham (1984) noted potential biological advantages of nearshore migration, including the availability of productive food sources in shallow nearshore waters (such as eel grass meadows and swarms of mysid shrimp in kelp beds) and protective cover from predators provided by nearshore rocks, bottom topography, and kelp beds.

Further north, Green et al. (1992) conducted aerial surveys between April 1989 and September 1990[13] during which they sighted 57 gray whales (51 groups) off Washington and 225 gray whales (150 groups) off Oregon. All of the migrating whales observed off Washington were found greater than 3 miles (5 km) offshore, with a mean distance offshore for all southbound whales (Oregon and Washington) of 8.9 miles (14.3 km) compared to 5.0 miles (8.0 km) for northbound whales. At least two of the sightings occurred in the action area.

Pike (1962) used logbooks from the M/V *Pacific Ocean*, a fur seal research vessel operating during March to May of 1958 to 1960, to document gray whale northward migrations off the coast of Washington. Pike (1962) reported that most whales probably passed within 1.2 miles (1.9 km) of the coast during the spring northward migrations, noting that "many whales pass by close to shore where their presence is difficult to detect against the surf breaking along the rocky coast and boiling over Umatilla reef." These observations are similar to the results of Herzig and Mate (1984) and Poole (1984). Pike (1962) also described northbound whales farther offshore. Logbooks from the Umatilla Lightship, stationed 5.2 miles (8.4 km) from shore south of Cape Flattery at Umatilla Reef, reported many gray whales passing close to the lightship from March to May. Whales engaged in various behaviors such as playing, mating, circling, rolling, or feeding, often remaining in the area for up to 4 hours. Pike (1962) also noted sightings 5.8 miles (9.3 km) off Cape Flattery, and a sighting of two adults and one calf as far as 23 miles (37 km) off Cape Flattery. These sightings farther offshore along the Washington coast are consistent with those reported by the following researchers:

- Wilke and Fiscus (1961), who sighted over 200 gray whales in late April generally travelling north 6 to 17 miles (9 to 28 km) offshore, just south of the action area in waters over the relatively wide continental shelf between James and Destruction Islands

[13] Approximately 45 percent of these surveys occurred during December to May.

- Green et al. (1992), who reported a mean offshore distance of 5 miles (8 km) for northbound whales off Oregon and Washington
- Green et al. (1995), who documented phase-one northbound migrants off the coast of Washington from March 11 through 16, 1990, as far out as 12.4 miles (20 km) and averaging a distance of 7.3 miles (11.8 km)
- Calambokidis et al. (2009a), who sighted northbound whales during February to April that tended to be close to shore, with most about 6 miles (10 km) offshore

For the fall/winter southward migration, Herzig and Mate (1984) reported the farthest extent of southbound migrants off the coast of Oregon as 12.4 miles (20 km) from shore at depths less than 295.3 feet (90 m) (Herzig and Mate 1984). When Mate and Poff (1999) repeated the Oregon coast surveys of Herzig and Mate (1984) in 1999, they noted that whales were distributed farther offshore than described in the prior studies. Whereas Herzig and Mate (1984) had reported that 50 percent of both northbound and southbound migrants passed within 1 and 2 miles (1.6 and 3.2 km) from shore, Mate and Poff (1999) estimated that 60 percent of the southbound whales were 5 miles (8 km) or more offshore and 20 percent of the whales were within 3 miles (4.8 km) of shore. These results are consistent with Green et al. (1995), who documented two groups of whales at 14.3 miles (23 km) as the furthest southbound migrants sighted off the coast of Oregon during aerial surveys conducted from January 3 to 12, 1990, and five groups of whales at 26.7 miles (43 km) as the furthest southbound migrants off the coast of Washington. Calambokidis et al. (2009a) sighted gray whales in December and January off the central Washington coast travelling an average of 18 miles (29 km) offshore in depths of 413.4 feet (126 m).

Green et al. (1995) and Green et al. (1992) have noted a significant latitudinal variation between Oregon and Washington for offshore distances of both northbound and southbound migrations. Green et al. (1995) reported that southbound migrants averaged 15.7 miles (25.2 km) from shore off Washington and 7.4 miles (11.9 km) from shore off Oregon. Green et al. (1992) combined both northbound and southbound sightings and reported a statistically significant difference between migrants off Washington (average 11.5 miles [18.5 km] offshore) and migrants off Oregon (average 5.7 miles [9.2 km] offshore). Green et al. (1992) concluded that these differences indicate the width of the migration corridor changes in concert with changes in the shallower depth zones (i.e., the 131.2-foot [40-m] isobath, which is wider off the Washington coast). Green et al. (1995) hypothesized that the difference between offshore distances for northbound and southbound whales either supports the occurrence of a single, very broad

migratory corridor or the occurrence of alternate offshore routes. Like Poole (1984) had noted for the California Bight area, Green et al. (1995) concluded that some portions of the ENP gray whale population may take a more direct route between Washington and the central coast of Vancouver Island, rather than following the longer coastal route past Cape Flattery. Pike (1962) noted that the lighthouse keeper at Amphitrite Point (on the central coast of Vancouver north of Barkley Sound) reported seeing 1,000 northbound gray whales each spring but never seeing them traveling southbound. Shelden et al. (2000) neither confirmed nor rejected the hypothesis of a more direct offshore route but noted that distance offshore may not be a function of migration alone, because gray whales have been observed 31.1 miles (50 km) off the Vancouver Island coast and 28 to 56 miles (45 to 90 km) off the Washington coast during summer months when the whales are not migrating. Calambokidis et al. (2009a) also reported an unexpected cluster of gray whales 12 to 16 miles (20 to 25 km) off the central Washington coast during the summer.

More recently, Ford et al. (2013) tracked five northbound satellite-tagged gray whales (including three whales that had been sighted in the PCFG seasonal range), from Vancouver Island to southeastern Alaska. They concluded that the majority of whales use the more interior waters of Hecate Strait and Dixon Entrance as their migratory corridor between Vancouver Island and southeastern Alaska. This finding differs from the long-held belief that whales maintain a northwest trajectory along the outer coastline of Haida Gwaii (formerly the Queen Charlotte Islands) once they reach the northern tip of Vancouver Island (Ford et al. 2013). These authors also observed that most whales were within 6.2 miles (10 km) of Bonilla Island (adjacent to the British Columbia mainland), but a substantial portion (22 percent) migrated further offshore and it was likely that some animals passed too far to the west to detect from the island. Also, Calambokidis et al. (2014) noted that three whales tagged on May 31, 2012 and tracked for 3 to 7 days remained close to shore in localized areas and water depths consistent with gray whale feeding behavior. Two of these whales had previously been photo-identified in the PCFG range.

To summarize, northbound whales in the action area (or areas immediately adjacent to it in Washington coastal waters) tend to travel closer to shore than southbound whales. Although there is considerable variability in these sightings[14], the best available information indicates the following:

[14] Most of the sighting studies reported in this section come from ship- or plane-based surveys capable of covering large expanses of the coastal marine zone. For example, Green et al. (1992) flew aerial transects in the vicinity of the action area that extended from the coastline out to approximately 56 to 68 miles (90 to 110 km) offshore. Green et al.

- Northbound whales likely migrate within 23 miles (37 km) from shore (averaging 5 to 7 miles [8 to 11 km] offshore) and many whales travel close to shore where their presence can be difficult to detect (Pike 1962; Green et al. 1992; Green et al. 1995).
- Southbound whales have been reported migrating up to 27 miles (43 km) from shore (averaging 9 to 16 miles [14 to 26 km] offshore), with the possibility that some whales may travel far offshore so as to take a more direct route to and from the central coast of Vancouver Island (Pike 1962; Green et al. 1992; Green et al. 1995).

3.4.3.3.3 ENP Abundance and Trends

The ENP gray whale population recovered from numbers as low as 4,000 to 5,000 whales post exploitation (Henderson 1984) to a high of nearly 27,000 whales in 2016 (Durban et al. 2017), decreasing to just over 14,500 whales in 2023 (Eguchi et al. 2023a).[15] NMFS estimates gray whale population size based on systematic shore-based surveys conducted during the whales' southbound migration. Since 1967, NMFS has conducted shore-based counts of southbound gray whales near Carmel, California, at either Yankee Point or Granite Canyon stations (Rugh et al. 1999; Buckland and Breiwick 2002; Rugh et al. 2005; Rugh et al. 2008). NMFS selected these observation sites because the continental shelf and the corresponding gray whale migratory corridor are relatively narrow. Few whales migrate beyond the visual range (approximately 3.5 miles [5.6 km]) of observers on shore (Shelden and Laake 2002). Aerial surveys showed that 96 percent of southbound gray whales pass within 3 miles (4.8 km) of the shore (Sund and O'Connor 1974), and fewer than 2 percent of the whales migrate beyond the sighting range of observers (Shelden and Laake 2002). These methods and data have been reviewed and accepted by the IWC Scientific Committee and the IWC, the internationally recognized authority on large cetacean management.

Up until 2006, single observers conducted the southbound counts by working in 3-hour shifts throughout daylight hours from mid-December to mid or late-February (Rugh et al. 2005; Rugh et al. 2008). The observers worked independently, scanning the viewing area using binoculars with reticles (vertical marks in the optics) and magnetic compasses to track whale groups as they migrated past the station. When observers spotted gray whales, they hand-recorded the following data: 1) time of sighting, 2) horizontal bearing, 3) vertical angle, 4) pod size estimate, 5) calf sightings, 6) environmental conditions, and 7) any unusual behaviors (Rugh et al. 2005; Rugh et

(1995) questioned the feasibility of conducting accurate shore-based gray whale censuses along the Oregon and Washington coasts given the high proportion of whales sighted beyond a shore-based observer's range of view.

[15] All estimates and figures of ENP abundance are inclusive of the PCFG whales, which do not constitute a separate stock.

al. 2008). The horizontal bearing and vertical angle allowed for estimates of distance from shore. On most days during January, when whale counts are at their highest, paired, independent searches are conducted by having a second observer conduct counts nearby (in the same viewing area), but out of sight of the primary observer (i.e., the observers are stationed in separate observation sheds). These independent searches provided a test of the repeatability of the census effort. More detail about the survey protocols used is in Rugh et al. (1993), Shelden et al. (2004), Rugh et al. (2005), Rugh et al. (2008), and Durban et al. (2013).

Data were entered on a computer at the end of each day and field-checked. Following further quality reviews of the database, researchers compared sighting locations and counts from paired observers to establish the probability of missing whales within the viewing area. In the abundance analysis, correction factors were applied to data to account for 1) whales that passed during periods when observers were not present (before and after the census season, at night, or when visibility was poor); 2) whales within the viewing range of observers that were missed (i.e., one observer saw a whale, but the other did not); 3) differential sightability by observer, pod size, distance offshore, and various environmental conditions; 4) errors in pod size estimation; 5) covariance within the corrections because of variable sightability by pod size; and 6) differential travel rates between day and nighttime travel (Hobbs et al. 2004; Rugh et al. 2005; Rugh et al. 2008). Rugh et al. (2005) adjusted the correction factor for nighttime travel from 1.020 (SE equals 0.023), based on radio-tagged whales (Swartz et al. 1987), to 1.0875 (SE equals 0.0363), based on Perryman et al. (1999), where thermal imagery provided quantifiable evidence that whales pass the shore at a higher rate at nighttime.

In preparation for the 2009 IWC Implementation Review of aboriginal subsistence harvest catch limits for ENP gray whales, NMFS biologists at the National Marine Mammal Laboratory (NMML) re-examined the entire series of abundance estimates and considered new information regarding the best methods for expanding the sighting data to estimate population size. NMFS advised the IWC Scientific Committee that the Implementation Review should be delayed while NMML reviewed the entire series of abundance estimates. NMML researchers provided a workplan that elaborated on the revised methods they intended to apply in deriving estimates (including standardizing the various datasets and applying better pod size correction factors) (Breiwick et al. 2009). The researchers completed their review in December of 2009 and re-estimated abundance for all 23 surveys available at that time (Laake et al. 2012). Largely because of corrections for pod-size bias, the newly derived abundance estimates between 1967 and 1987 were generally larger than previous abundance estimates, while the opposite was the case for estimates between 1992 and 2006. As a result, Laake et al. (2012) noted that the revised estimates

yielded a substantially different trend than previously reported (Rugh et al. 2008), with the peak estimate being a decade earlier (1988 instead of 1998) and the predicted population trajectory remaining relatively flat since 1980.

NMFS researchers improved their survey methodology using a new counting technique starting during the 2006/2007 southbound migration (Durban et al. 2013). The new technique replaces the previous method of a single observer logging sightings on paper forms with an improved method using two observers and a computer to log and track individual pods. The two-observer method allows for a higher frequency of observations of each whale pod, because one observer is dedicated solely to observing pods and second observer focused on data recording and software tracking of pods. After comparing the old and new counting techniques during simultaneous (2006/2007 and 2007/2008) and independent (post-2006/2007) trials, Durban et al. (2013) concluded that the new approach yielded consistent and more precise estimates that were indicative of a stable population.

Table 3-5 lists abundance estimates of the gray whale population using the revised correction factors and techniques described in Laake (2012) and Durban et al. (2015). Population estimates are always subject to a certain level of uncertainty, and this is represented by the coefficient of variation (CV); a lower CV indicates a higher certainty that an estimate reflects the actual population size. Even though researchers provide point estimates, confidence statistics like the CV should be considered when reviewing abundance estimates and their precision. For example, the point estimate of the most recent abundance was 14,526 whales, but we can only be relatively certain that the true abundance in 2022/2023 was somewhere between 13,200 and 16,000 whales (using rounded figures for the 95 percent credible interval) (Eguchi et al. 2023a).

The pattern of population growth and decline represented in the time series of population abundance data for ENP gray whales suggests that large-scale fluctuations are not rare for this stock. The population has shown the ability to recover from declines, with increases seen after each of the previous declines. Following the 1999/2000 UME, the population increased to a high of more than 26,500 individuals. In 2017, Durban et al. noted that a recent 22 percent increase in ENP gray whale abundance over 2010/2011 levels was consistent with high observed and estimated calf production. The 2019/2020 estimation of calf production resulted in slightly higher estimates (by about 10 percent) than previously thought, largely due to how the updated model addressed uncertainty in unobserved periods (Stewart and Weller 2020). Increases in abundance observed prior to the 2019 UME supported hypotheses that gray whales may have been experiencing more favorable feeding

conditions in arctic waters due to a rise in ice-free habitat that might have resulted in increased primary productivity in the region (Perryman et al. 2002; Moore 2016)

The current UME coincides with the recent declines in abundance observed in the 2019/2020 (Stewart and Weller 2021a), 2021/2022 (Eguchi et al. 2022a) and 2022/2023 surveys (Eguchi et al. 2023a). As of September 26, 2023, a total of 688 stranded whales were recorded in Canada, Mexico, and the U.S. The number of strandings in this event are slightly higher compared to the 1999/2000 UME, resulting in a 46 percent decline from 2016 (highest recent abundance prior to the UME) to 2023 (Eguchi et al. 2023a).

Table 3-5. Gray whale population estimates from southbound sightings 1967/68 to 2022/23.

Year	Population Estimate	Statistical Interval[16]
1967/1968	13,426	10,952 - 15,900
1968/1969	14,548	12,267 - 16,829
1969/1970	14,553	12,186 - 16,920
1970/1971	12,771	10,743 - 14,799
1971/1972	11,079	9,060 - 13,098
1972/1973	17,365	14,642 - 20,088
1973/1974	17,375	14,582 - 20,168
1974/1975	15,290	12,773 - 17,807
1975/1976	17,564	14,603 - 20,525
1976/1977	18,377	15,495 - 21,259
1977/1978	19,538	16,168 - 22,908
1978/1979	15,384	12,972 - 17,796
1979/1980	19,763	16,548 - 22,978
1984/1985	23,499	19,400 - 27,598
1985/1986	22,921	19,237 - 26,605
1987/1988	26,916	23,856 - 29,976
1992/1993	15,762	13,661 - 17,863
1993/1994	20,103	17,936 - 22,270
1995/1996	20,944	18,440 - 23,448
1997/1998	21,135	18,318 - 23,952
2000/2001	16,369	14,412 - 18,326
2001/2002	16,033	13,865 - 18,201
2006/2007	19,126	16,464 - 21,788
Data above from Laake et al. (2012); Data below from Durban et al. (2013)		
2006/2007	20,750	18,860 - 23,320
2007/2008	17,820	16,150 - 19,920
2009/2010	21,210	19,420 - 23,250
2010/2011	20,990	19,230 - 22,900
Data below from Durban et al. (2017)		
2014/2015	28,790[17]	23,620 – 39,210
2015/2016	26,960	24,420 – 29,830

[16] Data reported in this column depict confidence intervals (CI) (1967/8-2006/7: Laake et al. 2012) and highest posterior density intervals (HDPI) (2007/8 onwards: Durban et al. 2013; 2015; 2017). Both are terms commonly used by researchers to describe the precision of a point estimate, depending on their method of statistical inference. For example, within a Bayesian statistical framework, HDPIs indicate that there is a relatively high probability (signaled by 95th percentile as an interval of certainty) that the true abundance estimate in 2010/2011 falls between 19,230 and 22,900 gray whales. In general, narrower intervals indicate more precise point estimates.

[17] While this value is the highest ever reported, it is not typically cited as such due to considerable uncertainty (i.e., large error bars) in the estimate compared to the subsequent year's more precise estimate of 26,960 (Durban et al. 2017).

Year	Population Estimate	Statistical Interval[16]
Data below from Stewart and Weller (2021a)		
2019/2020	20,580	18,700 – 22,870
Data below from Eguchi et al. (2022a and 2023a)		
2021/2022	16,650	15,170 – 18,335
2022/2023	14,526	13,195 – 16,040

Gray whale population estimates rely on the assumptions that all whales migrate as far south as Carmel, California when observers are studying the southward migration, and that most whales will pass offshore within view of the observers. It has not been demonstrated that the entire gray whale population migrates past Carmel every year (Laake et al. 1994; Rugh et al. 2005), illustrating the importance of obtaining a long time-series of estimates across years from which to determine the trend in population size. Observers conducted the last southbound count in 2022/2023 and plan to survey again in 2023/2024.

3.4.3.3.4 ENP Status, Carrying Capacity, and Related Estimates

As noted previously, the ENP gray whale population was removed from the ESA list of endangered and threatened wildlife in 1994 (59 FR 21094, June 16, 1994) when NMFS determined that the species had recovered to near its estimated original population size (approximately 21,000 animals) (58 FR 3121, January 7, 1993) and was neither in danger of extinction throughout all or a significant portion of its range, nor likely to again become endangered within the foreseeable future. Since the ENP stock of gray whales was delisted, several analyses have addressed the status and productivity of the stock. In 1994, Wade reported values of K and MNPL for the ENP gray whale stock based on then-current abundance estimates reported between 1967 and 1994. He estimated that the ENP gray whale population was at 51 to 97 percent of its K and that the rate of net production at the MNPL was 0.033 (95 percent confidence interval from 0.023 to 0.044) (Wade 1994). With input from the IWC Scientific Committee, Wade (2002) updated his analysis with 1995/1996 census data, employed an age and sex structured model, and incorporated an additional factor to deal with unexplained variations in the time series of abundance data.

Later, Wade and Perryman (2002) incorporated the census data from 1997/1998, 2000/2001, and 2001/2002, as well as the calf production data from the northward migration (1994 to 2001), into a more complete analysis to increase the precision of the K estimate. They used a generalized logistic model, which included the added variance of Wade (2002) in the analysis. Based on these data, Wade and Perryman (2002) estimated that the ENP stock was at or near its carrying capacity of 22,000 whales (confidence of 95 percent and confidence intervals ranging from 19,000 to 35,000 whales). The IWC Scientific Committee reviewed the Wade (2002) and Wade and

Perryman (2002) assessments and agreed that management advice could be formulated from the results. Both assessments indicated that the population was above the maximum sustainable yield level and was likely close to or above its unexploited equilibrium level (IWC 2002).

In 2008, Rugh et al. assessed data between 1967 and 2007 and included additional correction factors (e.g., to correct for whales not seen by observers at night) to estimate a K of 23,686 whales. Moreover, they identified potential problems in the way that previous abundance estimates had been calculated (especially with respect to estimation of pod size). Subsequently, Laake et al. (2009; 2012) developed a more consistent approach to abundance estimation that used a better model for pod-size bias with weaker assumptions. Laake et al. (2009; 2012) applied their estimation approach to re-estimate abundance for all 23 shore-based surveys available at the time.

Punt and Wade (2012) re-assessed the ENP gray whale stock using the revised abundance estimates from Laake et al. (2009; 2012). From that assessment, Punt and Wade (2012) estimated the 2009 population (posterior mean of 20,366) to be at 85 percent of K (posterior mean of 25,808), and at 129 percent of MNPL, with a probability of 0.884 (i.e., an 88 percent chance) that the population is above MNPL. Those results were consistent across all the model runs, with previous assessments, and supported a finding that the population was within OSP. In 2010, the IWC Scientific Committee reviewed the analysis by Laake et al. (2009) and adopted the revised abundance estimates for use in the Committee's assessment of aboriginal subsistence whaling for gray whales (IWC 2011a). The Committee also reviewed the analysis of Punt and Wade (2012) and agreed that the results were within the bounds considered in the Committee's gray whale assessment.

As noted in Subsection 3.4.3.3.2, ENP Seasonal Distribution, Migration, and Movements, sea ice cover and prey biomass heavily influence the life history of ENP gray whales (i.e. Moore 2000; Clark and Moore 2002; Pyenson and Lindberg 2011; Perryman et al. 2021; Moore et al. 2022; Joyce et al. 2023). Because gray whales maintain their body mass by foraging on large quantities of benthic crustaceans, they are sensitive to oceanographic and environmental fluctuations (Hoegh-Guldberg and Bruno 2010). Observations of changes to the timing of sea ice cover and retreat, as well as the structure of benthic infaunal communities in the Arctic as a result of rapidly changing oceanographic conditions may have translated to an impact on the carrying capacity for higher trophic organisms such as gray whales (Grebmeier et al. 2006; Grebmeier et al. 2010; Grebmeier et al. 2018; Huntington et al. 2020).

Recent work has established that gray whale carrying capacity may not only fluctuate with environmental conditions but may also experience extreme population booms and busts in response to a changing Arctic ecosystem. Stewart et al. (2023) constructed a demographic model of the ENP gray whale population using the long term datasets discussed previously, as well as detailed temporal data on sea ice cover and crustacean (prey) biomass in the Arctic summer feeding grounds. Stewart et al. (2023) estimated that the long-term average carrying capacity (K) was 22,062 (18,967 to 24,725), which was lower than the median of the annual carry capacity values (24,500, 95 percent CI 21,771 to 27,797). The authors found that gray whale population dynamics were strongly linked to prey access and biomass, meaning that in years with low prey biomass and low access to prey (i.e., high ice cover), gray whales experienced major mortality events. These factors were associated with the three major mortality events in the time series (including both the 1999-2000 and 2019-present UMEs) assessed in the paper (Stewart et al. 2023). While previous work has suggested that early sea ice retreat may benefit gray whales by increasing access to their prey base, Stewart et al. (2023) found that changing sea ice extent also affects benthic and pelagic communities in ways that may impact higher tropic species that inhabit these high latitude areas in the Arctic.

IWC Implementation Review of ENP Gray Whales

Subsection 1.2.4.1.3, IWC Aboriginal Subsistence Whaling, describes the IWC's principles and approaches to managing ASW. Under current IWC regulations, ASW of gray whales is only permitted for the Russian Federation and the United States. The Scientific Committee of the IWC has a standing working group (SWG) on the aboriginal whaling management procedure (AWMP) tasked with providing scientific advice on safe catch limits for aboriginal subsistence whaling operations that take into account scientific uncertainty and meet the IWC's management objectives. The key objectives (IWC 1995) guiding the SWG's evaluation are:

1. Ensure risks of extinction are not seriously increased (highest priority);
2. Enable harvests in perpetuity appropriate to cultural and nutritional requirements; and
3. Maintain stocks at highest net recruitment level, and if below that ensure they move towards it.

The goal of the AWMP evaluation is not to maximize whale catches but instead to determine whether the number of animals requested for aboriginal subsistence needs exceeds a safe catch limit for a particular stock of whales.

The SWG's advice involves using computer simulations to test various methods for determining catch limits; these methods are referred to as AWMPs. Simulations consist of replicated calculations of stock trajectories using plausible whaling scenarios and 100-year simulated management with each candidate AWMP (Givens 1999). These simulations take into account uncertainty in a large number of factors, including whale population structure, abundance and trends, historic and future catch levels, reproduction and survivorship, and environmental conditions. An AWMP comprises two components: an assessment and a strike limit algorithm (SLA). The assessment is a statistical procedure that attempts to estimate certain parameters or variables given the available data. The SLA is a rule that provides a safe catch limit/quota given the assessment estimates obtained (Givens 1999). The SLAs are intended for long-term use but are typically reviewed on a frequent basis (usually every 5 years in an Implementation Review) to take into account any new information. In addition, unscheduled Implementation Reviews can be initiated if new information, such as a major mortality event, creates a serious concern (IWC 2003).

In 2004, the Scientific Committee developed several candidate SLAs for gray whales that tested for a broad range of uncertainty in a variety of factors, including changes in maximum sustainable yield rate and level (MSYR and MSYL); model uncertainty; time-dependent changes in carrying capacity, natural mortality, and productivity; episodic events; stochasticity; survey bias and variability; and survey frequency and errors in the historic catch series[18] (IWC 2005b). The overall performance of candidate SLAs was judged by a combination of (1) an examination of the detailed conservation and need satisfaction statistics (per the AWMP objectives identified above) for each of the Evaluation Trials and Robustness Trials[19], and (2) human integration of these results in the context of the relative plausibility each SWG member assigns to the individual trials. The Scientific Committee presented the IWC with its recommended gray whale SLA in 2004, and this was endorsed by the Commission (IWC 2005a; IWC 2005b), which noted that "…this SLA meets the objectives of the Commission set out in 1994 and represents the best scientific advice that the Committee can offer the Commission with respect to the management of the eastern North Pacific stock of gray whales."[20] Although the Commission went on to approve a

[18] As a conservative approach, the SLA operates with the assumption that all struck whales die.
[19] Simulation trials are divided into those considered most likely (the base-case or "Evaluation" trials) and those considered less plausible, but for which performance should be adequate ("Robustness" trials) (Punt and Donovan 2007).
[20] In response to concerns about what might happen if no gray whale surveys occur for longer than a 10-year period, the Chair of the SWG explained that, consistent with IWC deliberations in 2002, "unless an

catch limit that was consistent with the joint Russian Federation/U.S. request (140 whales per year), the Scientific Committee determined that up to 463 ENP whales per year was a sustainable take for at least the medium term (approximately 30 years) and a level of take that is "likely to allow the population to remain above maximum sustained yield level" (IWC 2003).

The next scheduled Implementation Review (in 2009) was postponed because a number of key analyses were not ready in time. In the 2010 Implementation Review for ENP gray whales, the Scientific Committee concluded that the ENP population as a whole was in "a healthy state" and that the gray whale SLA could continue to be used to provide advice on the Russian (Chukotkan) hunt (IWC 2011a). That advice translated to aboriginal harvest levels in the IWC schedule at the time (IWC 2012a; NMFS 2012a) that set a 6-year[21] catch limit for 2013 through 2018 of 744 ENP gray whales, limited to 140 whales per year (reviewable annually by the IWC and its Scientific Committee).

In 2011, the IWC Scientific Committee affirmed that "the Gray Whale SLA remains the appropriate tool to provide management advice for eastern North Pacific gray whales apart from the PCFG animals that are part of the ongoing work of the SWG on the AWMP for an Implementation Review" (IWC 2012l). At that time, the Committee also began a new Implementation Review focusing on SLA trials to take into account possible catches of PCFG whales in a Makah hunt (refer to Subsection of 3.4.3.4.4, PCFG Status, Carrying Capacity (K), and Related Estimates, IWC Implementation Review of PCFG Whales) and also recognized the need for additional studies on possible hunt-related conservation implications for WNP gray whales. The IWC completed an Implementation Review for ENP gray whales (including the PCFG) in 2012 (IWC 2012e), and, the SWG confirmed that "the proposed [Makah] management plan meets the conservation objectives of the Commission provided that if struck and lost animals are not proposed to be counted toward the APL [i.e., an allowable PCFG bycatch level], then a photo-identification research programme to monitor the relative probability of harvesting PCFG whales in the Makah U&A is undertaken each year and the results presented to the Scientific

agreed abundance estimate was forthcoming, then the block limit for the following block would be half that for the present block, after which it would revert to zero" (IWC 2005a).

[21] In 2012 the IWC agreed to move from annual to biennial meetings. As a result, the IWC changed the 5-year blocks for ENP gray whale catch limits to 6-year blocks. In its report, the Committee noted that while the gray whale SLAs support setting catch limits for blocks of even numbers of years (up to 8 years), it would not be appropriate for catches to be left unchanged if new abundance estimates were not available after 10 years (IWC 2012a).

Committee for evaluation" (see Subsection 3.4.3.4, Pacific Coast Feeding Group (PCFG) of Gray Whales).

After a review of the Makah Management Plan in 2018 (IWC 2018d), the IWC concluded that levels of harvest and other human-caused mortality are sustainable and that the management plan meets the IWC's conservations objectives for the ENP stock. The most recent Implementation Review occurred in 2020 (IWC 2021b), and the Scientific Committee recommended that "Gray Whale SLA and the Makah Management Plan remain the appropriate basis for the provision of advice on the Chukotkan and proposed Makah hunts." In 2023, the Scientific Committee reviewed new information on ENP gray whale abundance and stock structure and concluded that the SLA and Makah Management Plan are robust to the current UME as well as future mortality events (Punt et al. 2023, IWC 2023a). By a bilateral agreement between the two countries (Fominykh and Wulff 2023)[22], the ENP gray whale catch limit is currently allocated as follows:

- Chukotka Natives: up to 135 whales per year
- Makah Tribe: up to 5 whales per year

NMFS Stock Assessments and Other Reports for ENP Gray Whales

For all marine mammal stocks, we regularly prepare stock assessment reports (SARs) (e.g., Carretta et al. 2023) and, as needed, other reports (e.g., Harris et al. 2022, Eguchi et al. 2023a) that include minimum abundance estimates, a calculation of the PBR for the stock, and an assessment of whether all human-caused mortality exceeds PBR. If the annual average human-caused mortality remains below PBR, a stock at OSP will remain there, and any stock below OSP will continue to grow and will achieve OSP (Wade and Angliss 1997; Wade 1998). As long as the mortality average over the 3-year period is less than PBR, it is considered sustainable within the framework of the PBR management strategy (Wade and Angliss 1997).

In the most recent SAR for ENP gray whales, Carretta et al. (2023) reported that, with an abundance estimate of 26,960 whales, the stock was within OSP (based on an estimated carrying capacity of 25,808 whales in 2009; Punt and Wade 2012). However, Carretta et al. (2023) recognized that the abundance will fluctuate as the population adjusts to natural- and human-caused factors affecting the carrying capacity of the environment (see Rugh et al. 2005; Rugh et al. 2008; Stewart et al. 2023). Populations close to or at the carrying capacity of the environment

[22] The agreements also include notification commitments and states that the two countries may hold discussions regarding the transfer of unused takes from one native group to the other.

are more susceptible to fluctuations in the environment (Moore et al. 2001). The correlation between gray whale calf production and environmental conditions in the Bering Sea (Perryman et al. 2002; 2021) may reflect this. Overall, the population nearly doubled in size over the first 20 years of monitoring and has fluctuated for the last 30 years, with a recent increase to nearly 27,000 whales (prior to the onset of the UME). For this reason, it can be predicted that the population will undergo fluctuations in the future that may be similar to the 2-year mortality event that occurred in 1999 to 2000 (Norman et al. 2000; Pérez-Cortés et al. 1999; Brownell et al. 2001; Gulland et al. 2005).

For purposes of this FEIS, we calculated several informational PBRs using the most recent abundance data and different recovery factors. Based on abundance estimates published since the latest stock assessment report (Carretta et al. 2023), i.e., Eguchi et al.'s (2023a) minimum abundance estimate of 13,190, and using the Rmax of 0.062 and a recovery factor of 1, as are used in the most recent SAR, the PBR value for the ENP population would be 409.

Given the uncertainty in the carrying capacity estimates for the ENP gray whale stock discussed above, we calculated an additional, informational estimate of PBR for ENP gray whales. According to the GAMMS, a recovery factor of 1 is to be used for stocks above MNPL in calculating PBR, while a recovery factor of 0.5 is to be used for stocks of unknown status. We calculated a potential estimate of PBR here for informational purposes using a recovery factor of 0.5. The informational PBR is 204 based on a minimum population size (Nmin) of 13,190 whales (Eguchi et al. 2023a) and one-half of the estimated Rmax of 0.062, calculated thus: 13,190 x 0.031 x 0.5 = 204. This PBR estimate is precautionary and likely to be underestimates given the currently available information.

The annual average human-caused mortality and serious injury between 2014 and 2018 was 131 gray whales (Carretta et al. 2023). The average human-caused mortality includes annual mortality associated with the Chukotka Native aboriginal harvest (119 whales), commercial fisheries (9.3 whales), vessel strikes (1.8 whales), marine debris (0.4 whales), and illegal hunts (0.2 whales).

The estimate of human-casued mortality is considerably lower than the informational PBR estimates of 409 and 204. These PBR estimates are also higher than the strike limit of 140 whales per year that the IWC Scientific Committee considered would not harm the stock (IWC 2018a). Table 3-6 summarizes estimated levels of PBR and annual human-caused mortality and serious injury reported in stock assessment reports from 1998 through 2021.

Table 3-6. ENP gray whale human-caused mortality estimates from NMFS Stock Assessment Reports (SARs) 1998 to 2022.

SAR Year	Publication Date – NMFS Citation	PBR	Estimated Annual Level of Human-caused Mortality and Serious Injury[1]

1. These estimates are typically based on recent 5-year averages.
2. This is the first reporting in the SAR of the whale killed near Neah Bay in September 2007.
3. Beginning in 2012, responsibility for the gray whale SAR was transferred to the NMFS Southwest Fisheries Science Center.

Summary

The most recent SAR does not consider the recent changes in the environmental conditions of the Arctic. As described above, carrying capacity is the population level that can be supported in the ecosystem as determined by the natural elements, such as food, predation, temperature, ice cover, etc. Thus, it is possible that the changes in the Arctic's environmental conditions have altered the carrying capacity of the environment for ENP gray whales and, thus, the OSP range since Punt and Wade (2012) conducted their analysis. Populations at or near carrying capacity experience heightened competition for resources and decreased reproductive success. These populations are more susceptible to fluctuations in their environment. This may be the case for the ENP gray whale stock which appears to be fluctuating at or near carrying capacity (Carretta et al. 2023) (Figure 3-7). Evidence of this stock's resilience includes:

- Significant population increase from depressed levels in the 1960s;
- Rebound from a significant die-off in 1999/2000;
- Persistence and growth despite aboriginal subsistence harvest averaging more than 119 whales per year since 1985, including 108 to 143 whales harvested per year since the die-off in 1999/2000 (refer to Subsection 3.17.3.2, Worldwide Whaling);
- Flexible feeding adaptations that allow whales to switch between benthic and pelagic prey;
- Potential range expansion, including recent winter-time use of the Arctic and sightings of several gray whales in the Atlantic/Mediterranean and off western Africa.

In addition, current estimates of human-caused mortality are within the informational estimates of PBR calculated above. As described in Subsection 3.4.2.1.5, Implementing the PBR Approach,

maintaining human-caused mortality at or below the PBR level will support stocks within OSP in maintaining OSP, and for stocks below OSP, in achieving OSP.

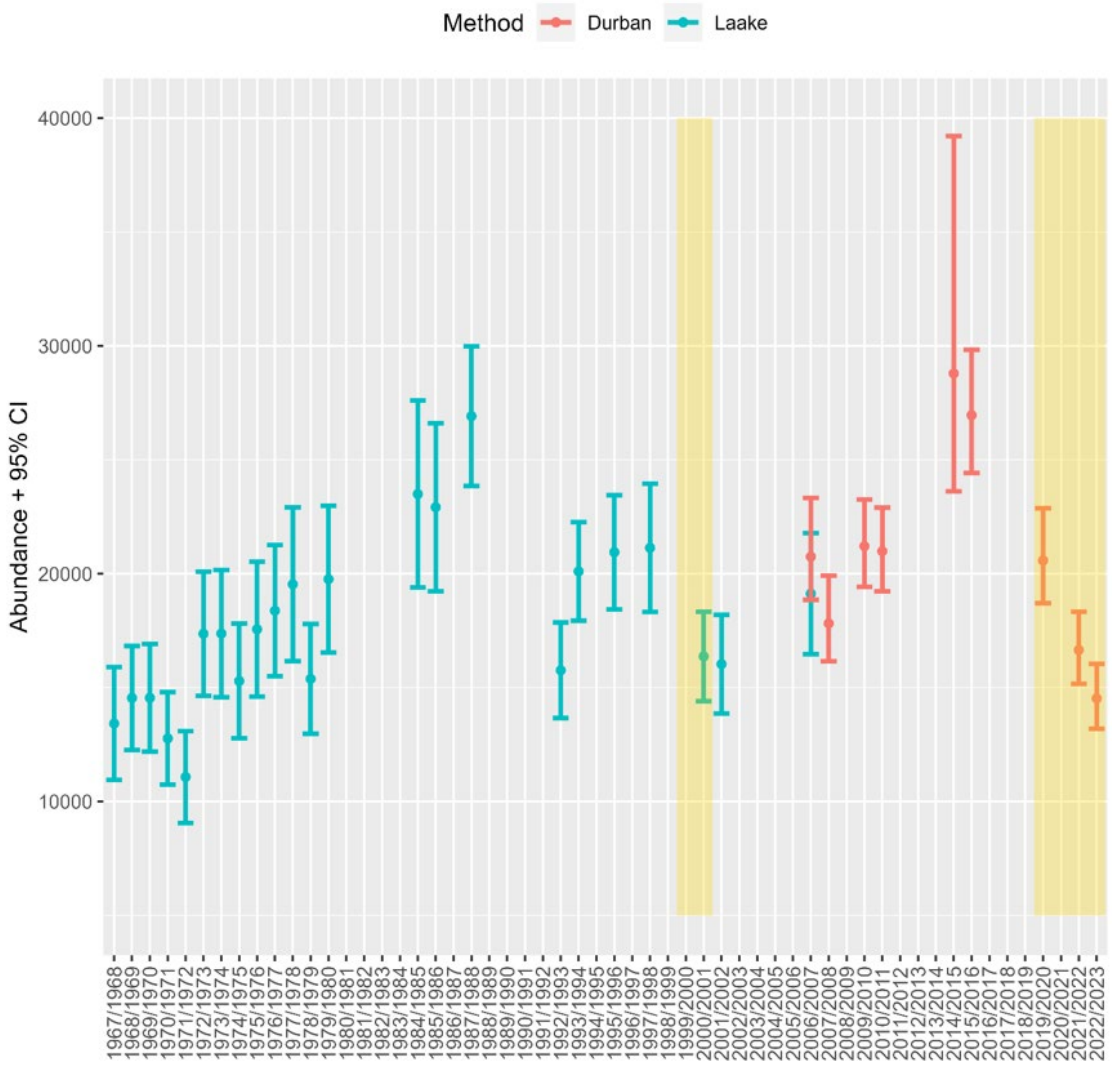

Figure 3-7. ENP gray whale abundance, 1967 to 2022/2023. Dual estimates for 2006 reflect the change in counting technique described in Durban et al. (2015). Figure from Eguchi et al. (2023a).

3.4.3.4 Pacific Coast Feeding Group (PCFG) of Gray Whales

Not all ENP gray whales make the full migration every year to feeding grounds north of the Alaska Peninsula/Aleutian Islands (Figure 3-3). Since the 1920s, gray whales have been documented feeding south of the Aleutians during the late spring, summer, and fall, past the times typically associated with the end of the spring northward migration and before the times typically associated with the onset of the fall southward migration. Between late spring and fall, gray whales have been observed off coastal Mexico (Patten and Samaras 1977); southern, central, and

northern California (Mallonée 1991; Calambokidis et al. 2004a); southern and central Oregon (Herzig and Mate 1984; Sumich 1984); northern Washington and northern Puget Sound; southwest and western Vancouver Island; British Columbia and north British Columbia (Darling 1984); and Sitka and Kodiak, Alaska (Calambokidis et al. 2002; Calambokidis et al. 2004a; Moore et al. 2007; Gosho et al. 2011). Feeding gray whales occurred off California even in the 1920s when population numbers were very low (Clapham et al. 1997; Moore et al. 2007).

In the literature, these observations have often been described as summer sightings (Gosho et al. 2001), and researchers have used the term 'summer' to refer to a longer period than is generally associated with the season, describing sightings off the Washington coast between June 1 and November 30 as summer feeding (e.g., Calambokidis et al. 2002; Calambokidis et al. 2004a). Whales seen during this period have been variously termed summer feeders, summer residents, summer population, seasonal residents, stragglers, the Washington feeding aggregation, the summer feeding aggregation, the southern feeding group, the Pacific Northwest feeding aggregation, the Pacific Coast Feeding Aggregation (PCFA)[23], and Pacific Coast Feeding Group (PCFG) (Pike 1962; Darling 1984; Quan 2000; NMFS 2001a; Calambokidis et al. 2002; Calambokidis et al. 2004a; Moore et al. 2007; Frasier et al. 2011; IWC 2010a).

In our 2008 draft EIS (NMFS 2008a), we noted that "[t]here is no evidence that the whales feeding in this portion of the summer range [the PCFG range] are genetically or demographically unique, and both NMFS and the IWC continue to treat ENP gray whales as a single stock for management purposes." Since then, various studies and reviews by NMFS, IWC, and other scientists have revealed genetic evidence relevant to demographic independence (Subsection 3.4.2.1.6, Stock Assessment Reports). The SAR has noted that the PCFG of gray whales may warrant consideration as a stock at some point. The following subsections describe the current state of knowledge about the whales in the PCFG range and specifically about PCFG whales that have been sighted in the area from Oregon to Southern Vancouver Island (OR-SVI) and in the Makah U&A, which is within the OR-SVI.

This FEIS focuses on those PCFG whales that have been sighted in the Makah U&A in response to the Ninth Circuit decision in *Anderson v. Evans* (2004). The court found that the geographic

[23] PCFA was the term used in the *Anderson v. Evans* case, the Tribe's waiver application, and the 2008 DEIS, but it is now superseded by the term PCFG. As defined by the Tribe, the PCFA is "any Eastern North Pacific gray whale found in the photo-identification database maintained by NOAA's National Marine Mammal Laboratory (NMML) which has been observed south of Alaska from June 1 through November 30 in any year."

scale of our inquiry in the 2001 EA at issue in that case was not sufficiently fine. The court concluded that we must consider not just effects to the PCFG whales but effects to whales observed in the Makah Tribe's U&A. The court referred to these whales as the "relatively small group of whales [that] comes into the area of the Tribe's hunt each summer,... about sixty percent of [which] are returning whales (although, again, not necessarily whales returning annually)" (*Anderson v. Evans* 2004). In holding that NMFS was required to prepare an EIS, the court focused on impacts to the "local area."

> *Even if the eastern Pacific gray whales overall or the smaller PCFA group of whales are not significantly impacted by the Makah Tribe's whaling, the summer whale population in the local Washington area may be significantly affected. Such local effects are a basis for a finding that there will be a significant impact from the Tribe's hunts. See 40 C.F.R. § 1508.27(a). Thus, if there are substantial questions about the impact on the number of whales who frequent the Strait of Juan de Fuca and the northern Washington Coast, an EIS must be prepared (Anderson v. Evans 2004).*

In addition to focusing on PCFG whales sighted in the Makah U&A, this FEIS considers PCFG whales sighted in the larger OR-SVI as the Tribe's application for a waiver proposed to use the abundance of those whales as the basis for estimating the allowable annual harvest of PCFG whales. They proposed this method due to the high degree of mixing of whales seen in the Makah U&A and in this larger area. In this FEIS, we define these entities as follows:

PCFG whales: Gray whales observed in at least 2 years between June 1 and November 30 in the PCFG area (between 41° N and 52° N) and entered into the Cascadia Research Collective's photo-identification catalog. For purposes of determining whether a harvested whale is a PCFG whale (i.e., counts against a bycatch or mortality limit), the Tribe's proposal under Alternative 2 would include cataloged whales seen in at least 1 year, while the other action alternatives would include cataloged whales seen in 2 or more years. Alternative 7, the preferred alternative, would assume any whale struck, struck and lost, or approached during the summer hunt time period to be a PCFG whale.

OR-SVI whales: PCFG whales observed in any survey area from southern Oregon to southern Vancouver Island (excluding areas in Puget Sound) from June 1 to November 30.

Makah U&A whales: PCFG whales observed in either the northern Washington survey area (from Cape Alava to Cape Flattery) or Strait of Juan de Fuca survey area (from Cape Flattery to Admiralty Inlet) from June 1 to November 30.

See Figure 3-9 for a map of the spatial areas mentioned above.

3.4.3.4.1 PCFG Population Structure

Although the 2008 DEIS referred to the Pacific Coast Feeding Aggregation, the currently accepted term is PCFG, originating from the IWC's 2010 Scientific Committee report (IWC 2010a) that states "the Committee agrees to refer to the animals that spend the spring, summer and autumn feeding in coastal waters of the Pacific coast of North America from California to southeast Alaska as the Pacific Coast Feeding Group or PCFG" (see also Subsection 3.4.3.1.2, Global Distribution and Population Structure). In that report the Committee also noted that research by Calambokidis et al. (2010)[24] had identified two groups of gray whales using the Pacific Northwest after June 1: (1) PCFG whales that return frequently and account for the majority of sightings and (2) a second group of apparent "stragglers" from the migration seen in only 1 year, generally for shorter periods and in more limited areas. Moreover, after reviewing results from photo-identification, telemetry, and genetic studies available in 2010 (i.e., Calambokidis et al. 2010; Mate et al. 2010; Frasier et al. 2011), the Committee agreed that the hypothesis of the PCFG being a demographically distinct feeding group was plausible and warranted further investigation (IWC 2010a). Subsequent IWC investigations have centered on developing and evaluating strike limit algorithms for hunting in the Pacific Northwest, with a primary emphasis on the PCFG (Subsection 3.4.3.4, PCFG Status, Carrying Capacity, and Related Estimates, IWC Implementation Review of PCFG Whales).

The IWC's general description of the PCFG was refined at a 2011 workshop (consisting of the IWC's standing working group on the development of the Aboriginal Whaling Management Procedure) focused on the proposed Makah hunt and the PCFG (IWC 2011b). A key analysis reviewed at that workshop was the photo-identification study by Calambokidis et al. (2010) which corroborated earlier observations (e.g., Calambokidis 2004a) that there is a concentration of gray whale sightings in survey areas ranging from Northern California ("NCA" at 41° N Latitude) and northern British Columbia ("NBC" at 52° N Latitude), and that whales seen after June 1 were more likely to be seen multiple times, in multiple years, and multiple survey areas than whales seen before June 1. The workshop also noted that genetic samples had been taken from across this range and few if any whales are still migrating north through the 41° N to 52° N

[24] This research is part of an ongoing collaborative effort among a number of research groups to compile and identify individual gray whales photographed in 15 survey areas from southern California to Kodiak, Alaska. The photo-identification data are cataloged in a database maintained by the non-governmental organization Cascadia Research Collective in Olympia, Washington.

region from June 1 to November 30 (IWC 2011b). The resultant PCFG definition was articulated in the IWC's 2011 Report of the Scientific Committee (IWC 2011c) as:

> *PCFG whales are defined as gray whales observed (i.e., photographed) in multiple years between 1 June and 30 November in the PCFG area (between 41° N and 52° N).*

The Committee's report goes on to note that "[n]ot all whales seen within the PCFG area at this time will be PCFG whales and some PCFG whales will be found outside of the PCFG area at various times during the year" (IWC 2011c). The most recent NMFS stock assessment report for gray whales (Carretta et al. 2023) concludes that "the PCFG appears to be a distinct feeding aggregation and may one day warrant consideration as a distinct stock."[25]

The current definition for the PCFG is somewhat more restrictive than the Tribe's description of the Pacific Coast Feeding Aggregation (PCFA) used in its waiver request that states, "for the purposes of this request, the PCFA is defined as any Eastern North Pacific gray whale found in the photo-identification database maintained by NOAA's National Marine Mammal Laboratory (NMML) which has been observed south of Alaska from June 1 through November 30 in any year." The main differences between the current PCFG definition and the definition in the Tribe's application are: (1) the photo-identification database/catalog is actually maintained by the Cascadia Research Collective, not NMML[26]; and (2) the Tribe's proposal would limit the incidental killing of a potentially larger group of whales, in that it would take into account animals sighted even *once* as well as animals sighted *south* of 41° N (Northern California) during June 1 to November 30.

PCFG Genetics and Recruitment

Early genetic studies of PCFG whales focused on evaluating recruitment patterns, with simulations indicating that genetic differences would be detected if the PCFG originated from a

[25] Although interior waters making up Puget Sound are within the PCFG latitudinal boundaries of 41° N to 52° N, whales sighted in Puget Sound were not included in the IWC analysis and are considered outside the range of the PCFG. Previous research has found that the few whales sighted in Puget Sound are typically seen only in the spring (especially in northern Puget Sound), are less likely to be seen in multiple years and regions, and likely represent migratory animals (Calambokidis et al. 2002; Calambokidis et al. 2003; Calambokidis et al. 2004a; Calambokidis 2008; Calambokidis et al. 2009a).

[26] NMML scientists do provide photographs that are included in the catalog.

single colonization event in the past 40 to 100 years without subsequent external recruitment[27] (Ramakrishnan and Taylor 2001). However, a subsequent analysis by Steeves et al. (2001) failed to detect differences when 16 samples collected from known PCFG whales using Clayoquot Sound, British Columbia, were compared with 41 samples collected from individuals presumably feeding farther north. Additional genetic analysis with an extended set of samples (n=45) collected from whales within the PCFG range indicated that genetic diversity and the number of mtDNA haplotypes were greater than expected (based on simulations) if recruitment into the PCFG were exclusively internal (Ramakrishnan et al. 2001). However, both simulation-based studies focused on evaluating only the hypothesis of founding by a single and recent colonization event and did not evaluate alternative scenarios, such as recruitment of whales from other areas into the PCFG (Ramakrishnan and Taylor 2001; Ramakrishnan et al. 2001).

Frasier et al. (2011) compared mtDNA sequence data from 40 individuals from the PCFG summer range with published sequences generated from 105 samples collected from ENP gray whales, most of which stranded along the migratory route between southern California and Chukotka, Russia (LeDuc et al. 2002). The mtDNA haplotype diversity found among samples of the PCFG was high and similar to the larger ENP samples, but significant differences in mtDNA haplotype distribution and in estimates of long-term effective population size were found. Based on these results, Frasier et al. (2011) concluded that the PCFG qualifies as a separate management unit under the criteria of Moritz (1994) and Palsbøll et al. (2007)[28]. The authors noted that PCFG whales likely mate with the rest of the ENP population and that their findings were the result of maternally-directed site fidelity of whales to different feeding grounds. In other words, calves (male or female) who accompanied their mothers to the feeding ground would return in subsequent years.

A subsequent study by Lang et al. (2014) assessed stock structure of whales that use feeding grounds in the ENP. Small but statistically significant mtDNA differentiation was found when samples from PCFG whales were compared to samples from whales feeding north of the Aleutians. No significant differences were found when these same comparisons were made using

[27] External recruitment refers to the addition of individuals to a group via animals that were previously located outside the group (i.e., immigrants). Internal recruitment refers to births.
[28] Moritz (1994) defined 'management units' as populations with significant divergence of allele frequencies at nuclear or mitochondrial loci, regardless of the phylogenetic distinctiveness of the alleles. Palsbøll et al. (2007) proposed that the identification of such units from population genetic data should be based upon the amount of genetic divergence at which populations become demographically independent instead of a criterion that focuses on rejecting a hypothesis of random mating.

nuclear data (12 microsatellite loci). Based on these results, the authors concluded that 1) use of some feeding areas is being influenced by internal recruitment (e.g., matrilineal fidelity), and 2) individuals from different feeding grounds may interbreed. The level of mtDNA differentiation identified, while statistically significant, was low, and the mtDNA haplotype diversity found within the PCFG was similar to that found in the northern feeding area strata. Lang et al. (2014) suggested that these findings could be indicative of relatively recent establishment of the PCFG but could also be consistent with a scenario in which external recruitment into the PCFG is occurring.

A study by D'Intino et al. (2012) compared whales sampled off Vancouver Island and representing the PCFG (n=82 animals) to whales sampled at the calving lagoon at San Ignacio (n=51 animals). They found no nuclear DNA evidence for population differentiation between these two areas, indicating that that the two sampled groups come from the same interbreeding population. They concluded that taken together, the available photo-identification and genetic data indicate seasonal subdivision of gray whales on summer feeding grounds but with no such substructuring during the mating season, where all individuals represent one gene pool, and that maternally-directed site fidelity to different feeding areas (such as the PCFG range) leads to mtDNA differentiation among feeding areas.

Researchers have documented differences in mtDNA that reflect strong site fidelity to summer feeding areas for humpback whales in the North Atlantic and North Pacific (Baker et al. 1990; Larsen et al. 1996). The documented mtDNA differences between humpbacks in different feeding areas indicate that calves learn to use specific feeding areas from their mothers, and they subsequently pass that knowledge to their offspring (a concept known as maternally directed fidelity or familial recruitment) (Palsbøll et al. 1995; Larsen et al. 1996; Palsbøll et al. 1997). Long-term re-sighting histories of individual humpback whales in the North Atlantic further demonstrate very high annual return rates to specific feeding grounds and minimal interchange among such regions (Clapham et al. 1993; Stevick et al. 2006). The apparent difference in site fidelity between humpback and gray whales (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements) may be due to the geographic structure of the migratory route between the summer and winter grounds. For humpback whales, the migratory routes to isolated feeding areas are direct and often cross deep ocean basins (Baker et al. 1990; Calambokidis et al. 1996; Clapham and Mead 1999; Calambokidis et al. 2002). In contrast, gray whales follow a coastal migratory route that passes PCFG feeding areas. Thus, even if mothers introduce calves to

a feeding area, there is a natural mechanism for all gray whales to adopt and/or revisit productive feeding areas (Calambokidis et al. 2004a).

Photo-identification studies also underscore the possible role of matrilineal fidelity in maintaining the PCFG as well as the significant variability in whale sightings in the area. Calambokidis and Perez (2017a) reviewed the most recent mother-calf data and concluded that a high percentage of surviving calves appear to become part of the PCFG[29]. Between 1993 and 2015, they documented 102 calves accompanying 62 different, probable mothers identified as PCFG whales, with a high proportion of these mother/calf pairs seen from 2012 to 2015 (11 to 18 each year). The increase in sightings may be due to an increase in births in those years, an increase in survey effort focused on identifying calf/mother pairs, or some combination thereof. Still, these calf data likely represent a minimum estimate because: 1) most surveys took place after the mean date of weaning (1 August), so some calves may not have been identified as such because they had already weaned from their mothers, and 2) larger calves may not be identified as calves even when they are with mothers (human error). Calambokidis and Perez (2017a) went on to analyze the re-sighting history of calves and found that 65 percent were seen in a year subsequent to the year they were calves. The 35 percent not seen in a subsequent year could result from the calf dying, the calf not returning to the area or not re-sighted during its return, or the calf not being recognized by photo-identification because of changes in its markings.

Calambokidis and Perez (2017b) also studied photographs of migrating gray whales to determine if PCFG whales remain associated during migration, in addition to the time they spend together in their summer feeding grounds. Using photographs from marine naturalists in Southern California from 2013 through 2015, they were able to identify 26 PCFG whales—15 females and 11 males— on 21 occasions (including two re-encounters of the same group of whales on the same day). In nine of those 21 sightings (42 percent), multiple PCFG animals were present in the group. Of the nine groups containing multiple PCFG whales, six groups contained multiple animals of known sex, four of which contained both males and females. These associations were present during both the northbound and southbound migrations. Calambokidis and Perez (2017b) concluded that these associations during migration increase the probability of PCFG association

[29] Whales are identified as calves when they are accompanied by their mother; thus, once the calf is weaned, it may not be recognized as a calf and this may, in turn, affect calf estimates.

in the wintering grounds andincreases the chances for breeding within the PCFG, even in the presence of non-PCFG animals.

The IWC Subcommittee on Gray Whales reviewed these data in the Fourth Rangewide Workshop on the Status of North Pacific Gray Whales in 2017 (IWC 2017). It determined that although the associations observed by Calambokidis and Perez (2017b) may provide an opportunity for breeding to occur within the PCFG, the co-occurrence of PCFG whales during migration does not necessarily mean that they breed together. Furthermore, genetic analyses of PCFG whales and ENP whales sampled outside the PCFG range (i.e. on more northern feeding grounds and in the breeding lagoon) suggest that the sampled whales represent one breeding population subdivided based on maternally-directed feeding site fidelity. That is, the genetic data indicates that individuals from different feeding areas interbreed. Further, these studies have not ruled out the possibility that interbreeding between non- PCFG and PCFG animals is random (D'Intino et al. 2013; Lang et al. 2014; IWC 2017).

There is also evidence that whales with a demonstrated tendency to return to particular feeding grounds may behave differently as young animals or as mothers with calves. Weller et al. (2013) noted that many of the whales identified as calves off Sakhalin Island in the WNP are not re-sighted for many years subsequent to their birth year, but eventually they are again re-sighted in the area. This suggests that young animals may use other areas to feed during their first several years. Calambokidis et al. (2014) noted cases where females that had been regularly sighted in the PCFG area were subsequently sighted as mothers with a calf but outside the PCFG area. Both of these examples highlight the difficulty in assessing whether new whales are external or internal recruits.

While the studies summarized above suggest that internal recruitment (e.g., via matrilineal fidelity) is important in structuring feeding ground use, other evidence suggests that external recruitment via immigration into the PCFG may be occurring. Lang and Martien (2012) used simulations to examine how much immigration into the PCFG could occur to produce results consistent with the empirical genetic (mtDNA) analyses. The results suggested that the plausible range of immigration is greater than 1 and fewer than 10 animals per year on top of a 2-year pulse of immigration (of 20 animals each year in 2000 and 2001, consistent with the findings by Calambokidis et al. (2014) that a higher than usual number of animals recruited into the PCFG in the years following the 1999 to 2000 gray whale UME [Subsection 3.4.3.1.7, Strandings]). Annual immigration of 4 animals (with the 2-year pulse of immigration) produced simulated results that were most consistent with the empirical data. From 2002-2015, the PCFG increased

from 197 to 243 animals, which amounts to an annual average increase of 3.5 whales annually over 13 years (Calambokidis et al. 2017).

Calambokidis et al. (2014) analyzed PCFG sighting data and noted that new whales (i.e., not previously seen) have continued to appear annually and many of these new whales have subsequently returned and been re-sighted as "recruits." It has also been observed that whales with a longer minimum tenure in the first year they were sighted have higher probability of return (i.e., do not permanently emigrate) (Calambokidis et al. 2004a; Weller et al. 2013; Calambokidis et al. 2014). This relationship supports a hypothesis that whales are more likely to return if they find a suitable prey base during their first year in the range of the PCFG during June 1 to November 30.

Weller et al. (2013) reviewed sighting data for non-calf animals from 1998 to 2009 and found that the recruits:transients ratio in a given year was about 50:50, which is very similar to the 49:51 ratio seen in the more recent and larger data set (1996 to 2011) analyzed by Calambokidis et al. (2014). Calambokidis et al. (2014) also found that during surveys in the PCFG range from 1999 to 2011 (when photo-identification efforts expanded to cover all survey regions), an average of 34 new whales (ranging from 8 to 69) were seen each year. During that time, an average of 14.3 whales (ranging from 1 to 30) were recruited each year, and most of these (12.5 on average) were not identified as calves. Calambokidis et al. (2014) also applied various methods to estimate the abundance of PCFG whales (Subsection 3.4.3.4.3, PCFG Abundance and Trends). They observed that abundance estimates had been fairly stable since 2002, indicating that recruitment was being offset by losses (either whales dying or permanently emigrating).

In the most recent report on PCFG abundance, Harris et al. (2022) report that an average of 34 new whales (ranging from 8 to 71) were seen each year in the PCFG survey area from 1999 to 2020, and an average of 14 whales were seen again in a subsequent year (excluding 2020 as no recent data were available yet). This is consistent with the earlier studies.

Sex Ratio of PCFG Whales

Genetic studies by Frasier et al. (2011), D'Intino et al. (2013), and Lang et al. (2014) sampled dozens of whales (40 to 71 animals) in the PCFG range and found that females made up 58 to 60 percent of the samples (collected from 1994 to 2010). More recent analysis of 194 PCFG individuals biopsied between 1996 and 2015 revealed that 103 (53 percent) are female and 91 (47 percent) are male (Aimee Lang, pers. comm., Southwest Fisheries Science Center Biologist, February 26, 2020). Earlier studies (Steeves et al. 2001; Ramikrishnan et al. 2001) found a slight

male bias, but Lang et al. (2014) noted that results from those earlier studies may have been influenced by small sample sizes (Steeves et al. 2001 analyzed just 16 samples from known PCFG animals) or the laboratory assays used by Ramikrishnan et al. (2001). Based on this information, we estimate a sex ratio within the PCFG of approximately 50:50 males to females.

NMFS 2012 Workshop on Gray Whale Stock Identification

In the summer of 2012, NMFS convened a workshop with eight agency scientists (i.e., a Task Force) to conduct an objective scientific evaluation of gray whale stock structure as defined under the MMPA and implemented through NMFS' 2005 GAMMS (NMFS 2005b)[30]. Specifically, the Task Force was convened to provide advice on the primary question: Is the PCFG a 'population stock' under the MMPA and GAMMS? This question has management implications, including how future NMFS stock assessment reports address gray whale stock structure in the North Pacific, and how to interpret any new information in the context of the Makah Tribe's waiver request.

After reviewing the best existing scientific information available from photo-identification, genetics, tagging, and other studies within the context of the 2005 GAMMS, the Task Force concluded that there remains a substantial level of uncertainty in the strength of the lines of evidence supporting demographic independence of the PCFG. Consequently, the Task Force was unable to provide definitive advice as to whether the PCFG is a population stock under the MMPA and the GAMMS. Members of the Task Force ranged in their opinions from strongly agreeing to strongly disagreeing about whether the PCFG should be recognized as a separate stock. The Task Force emphasized that the PCFG is relatively small in number and uses a largely different ecosystem from that of the main ENP gray whale stock.

Key Task Force arguments *for* the PCFG being a demographically independent unit included:

- The PCFG is a feeding group that does not rely on the dynamics of a sub-arctic ecosystem, and this uniqueness may provide important flexibility to the species as a whole given potential challenges in a changing sub-arctic ecosystem.
- Persistent return of individual whales to specific feeding areas strongly suggests that site fidelity is key to maintaining gray whales as a functioning element of this ecosystem.

[30] The Task Force agreed to use the 2005 GAMMS during its deliberations because the 2011 draft GAMMS had not been formally approved. The Task Force also noted that the GAMMS 2005 definition for "demographic isolation" is essentially the same as the GAMMS 2011 definition for "demographic independence" in that neither implies true "isolation" within the context of the MMPA.

- Some genetic analyses (using mtDNA haplotype data) have shown low but significant differences between the PCFG and the larger ENP population, providing indirect evidence of internal recruitment and matrilineally-directed site fidelity to feeding grounds.
- Evidence of internal/calf recruitment that may actually be an underestimate because of survey limitations.

Key Task Force arguments *against* the PCFG being a demographically independent unit included:

- Various lines of evidence (e.g., genetic, photo-identification) indicate considerable and ongoing external recruitment into the PCFG; however, there is considerable uncertainty as to whether external recruitment exceeds internal recruitment.
- Other genetic analyses using mtDNA and nuclear DNA data have not shown significant differences between the PCFG and the larger ENP population.
- A sizable number—approximately 10 percent of the whales that occur in the PCFG area each summer/fall—are transients that otherwise feed north of the Aleutians and serve as a substantial and continuous source of potential recruitment into the PCFG.
- The annual coastal migration route of most ENP gray whales includes the habitat used by the PCFG, making it likely that external recruitment would fill any voids caused by whales being removed from the PCFG.

The Task Force also noted that while the status of the PCFG as a population stock was not resolved, continued research on these whales should be undertaken with particular attention dedicated to collecting data relevant to the question of stock identification.

We have not identified the PCFG as a population stock under the MMPA, nor are we aware of any existing studies concluding that the PCFG meets the criteria of a separate stock under the MMPA, but have stated that it may warrant consideration as a separate stock in the future (Carretta et al. 2023). If we were to determine that the PCFG did warrant consideration as a stock under the MMPA then we could take the step of classifying it as a 'prospective stock,' which would entail soliciting public comment and additional scientific information specifically addressing the prospective stock structure. The GAMMS (NMFS 2023b) note that prospective stocks are expected to become separate stocks in a timely manner unless additional evidence were produced to contradict the prospective stock structure.

3.4.3.4.2 PCFG Seasonal Distribution, Migration, and Movements

In a general sense, gray whales using the PCFG area exhibit a migratory pattern similar to that of whales in the larger ENP stock (Subsection 3.4.3.3.1, ENP Seasonal Distribution, Migration, and Movements). The following subsections summarize the current knowledge about how PCFG whales use these southern feeding grounds.

Unique Markings of Individual Whales and History of Survey Efforts

In the early 1970s, scientists discovered they could identify individual whales by dorsal area shape, scars, and coloration patterns that are visible above the surface of the water when the whales arch to dive (Darling 1984). Photographing and identifying individual whales, noting the location and time of sighting, and comparing photographs within and between years has allowed scientists to study abundance, distribution, movements, and survival of whales using the southern portion of the ENP gray whale summer range. Over time, researchers have established summer survey areas either because the area is one where whales were likely to be found feeding or because the area is one where a management activity occurs (for example, a counting station along the migration route or an area where a hunt is proposed). The following discussion focuses on survey areas because that is how data are collected, reported, and analyzed. Although a researcher's designation of a survey area will not necessarily correspond to areas that are biologically meaningful to individual whales or groups of whales, they are nevertheless useful for analyzing local effects.

From 1972 to 1981, researchers conducted photo-identification studies in survey areas off the west coast of Vancouver Island, British Columbia (Hatler and Darling 1974; Darling 1984). Both effort and survey areas varied between years. Survey effort ranged from less than 5 days in 1972 to 54 days in 1976. Five discrete areas were surveyed. Surveys began in the 24.9-mile [40-km] stretch of coast around Wickaninnish Bay near Tofino on the central west coast of Vancouver Island (surveyed from 1972 to 1981). Later surveys extended north to include three more discrete survey areas (Estevan Point, between Clayoquot Sound and Nootka Sound, surveyed from 1976 to 1981; Cape Scott, surveyed in 1977 and 1979; and Calvert Island, surveyed in 1977 and 1979), then survey efforts expanded south to include the West Coast Trail survey area (surveyed from 1979 to 1981). In 1976 and 1977, the greatest number of whales identified in any one summer was 34 (some individuals were re-sighted from prior years), corresponding to maximum effort and including 1 year when four of the five survey areas were surveyed (excluding West Coast Trail, which was added later in 1979). Flights to locate whales missed by the boat-based surveys were carried out weekly in 1976 and sporadically in other years. Sixty-three percent of the

identified whales were seen in more than one summer, and 37 percent were identified in only one summer (i.e., they were never re-sighted in a subsequent year). One whale was seen in 7 consecutive years and others were seen across spans of time as long as eight summers but were not seen in every summer.

On the basis of these data, Darling (1984) surmised that 35 to 50 whales were present during 1972 to 1981 off the coast of Vancouver Island in any one summer but they were not all the same whales each year. During 1975 to 1981, Darling (1984) identified 93 total individual whales that were present in this study area for at least 1 year. Darling (1984) noted that other researchers surveying in areas off of Oregon thought there were approximately 75 total individual whales identified each year of their effort, so he surmised that there were at least 100 gray whales in the British Columbia-Washington-Oregon area in any one summer.

Within-season and between-year movement of identified and re-sighted whales was also recorded. Some identified whales remained in the same survey area throughout the summer; for example, two whales remained in the Wickaninnish Bay survey area for at least 80 days. Other whales traveled considerable distances in search of food; for example, a whale identified in the Wickaninnish Bay survey area reappeared in the Estevan Point survey area 47.9 miles (77 km) away. Between years, identified whales reappeared at least 93.3 miles (150 km) away from where they were in a prior year.

From 1984 to 1993, researchers from Cascadia Research Collective conducted photo-identification studies of eight discrete survey areas in the inland waters of southern, central, and northern Puget Sound and Hood Canal; the Strait of Juan de Fuca; and the outer Washington coast, including Grays Harbor (Calambokidis et al. 1994). Survey efforts varied between summers and areas, ranging from 16 days in 1990 to 50 days in 1991. Calambokidis et al. (1994) developed a catalog of photo-identified whales; 76 individual photo-identified whales were in the catalog by 1993. Of these 76 photo-identified whales, only 17 whales (22.3 percent) were re-sighted in more than 1 year, either in the same area or a different area, including British Columbia. Between-year re-sightings of photo-identified whales were most common in the northern Puget Sound survey area, where five of seven identified whales were re-sighted in subsequent years.[31] They were least common in the southern and central Puget Sound and Hood Canal survey areas, where 1 of 18 identified whales was re-sighted in subsequent years.

[31] Sightings of gray whales in northern Puget Sound indicate that this area is used briefly each year as a spring-time feeding area for a small regular group of gray whales (Calambokidis et al. 2009a).

Individually identified whales were re-sighted an average of 47 days later, and the longest time between first and last sightings in a season was 112 days.

These photo-identification efforts collectively demonstrate that some of the gray whales feeding in the southern portion of the ENP summer range remain for extended periods and that some of the whales return to the same general feeding areas in later years, though not necessarily every year (Darling 1984; Calambokidis et al. 1994). The studies also demonstrate that many of the gray whales photo-identified were not re-sighted in subsequent years, that new individuals were photographed every year, and that some whales inhabited different areas in different years (Darling 1984; Calambokidis et al. 1994). These observations were important because they suggested a lack of strong site fidelity (returning to the same previously occupied breeding or feeding location), which can indicate that a particular group of animals is different from the rest of the population in a biologically meaningful way (i.e., genetic or behavioral differences). Such differences can indicate stock structure and demographic independence, which have management implications. Animals with strong site fidelity may be unlikely to move or select new habitats if their traditional habitat becomes less favorable (Switzer 1993; Quan 2000).

In response to the Makah Tribe's request to resume their traditional hunt of gray whales, we initiated photo-identification studies of gray whales off the coast of Washington in 1996 to better understand distribution (including site fidelity and habitat use) and abundance (Gearin and DeMaster 1997; Gosho et al. 1999; Gosho et al. 2001). This was a response to federal conservation and management obligations pursuant to the ESA monitoring plan following the 1994 delisting and also to our federal trust obligations triggered by the Makah Tribe's request to hunt gray whales (Gearin and DeMaster 1997). We were investigating whether the proposed level of harvest would impact whales sighted in the hunt area. We focused our survey efforts in the Strait of Juan de Fuca (from Tatoosh Island to Sekiu), the northern Washington coast (Tatoosh Island to Carroll Island), and southern Vancouver Island. We noted that the survey area had limitations and indicated that effort should be extended beyond these three areas south to Grays Harbor (the area surveyed by Calambokidis et al. 1999) and north to west Vancouver Island (the area surveyed by Darling 1984) to increase the probability of sighting gray whales in Washington and British Columbia waters (Gosho et al. 1999).

From 1998 to the present, we have funded and collaborated with Cascadia Research Collective, the Makah Tribe, and other researchers to conduct photo-identification surveys of gray whales, primarily in the range of the PCFG. This collaboration has allowed researchers to combine resources and results and cover broader survey areas within the southern portion of the ENP

summer range, from southern California to Kodiak Island (Figures 3-9 and 3-10). Effort within survey areas varied, and the number of days in which whales were seen from 1996 to 2012 (June to November) were highest in the survey areas along southern Vancouver Island and just north of Vancouver Island (Calambokidis et al. 2002; Calambokidis et al. 2004a; Calambokidis et al. 2014).

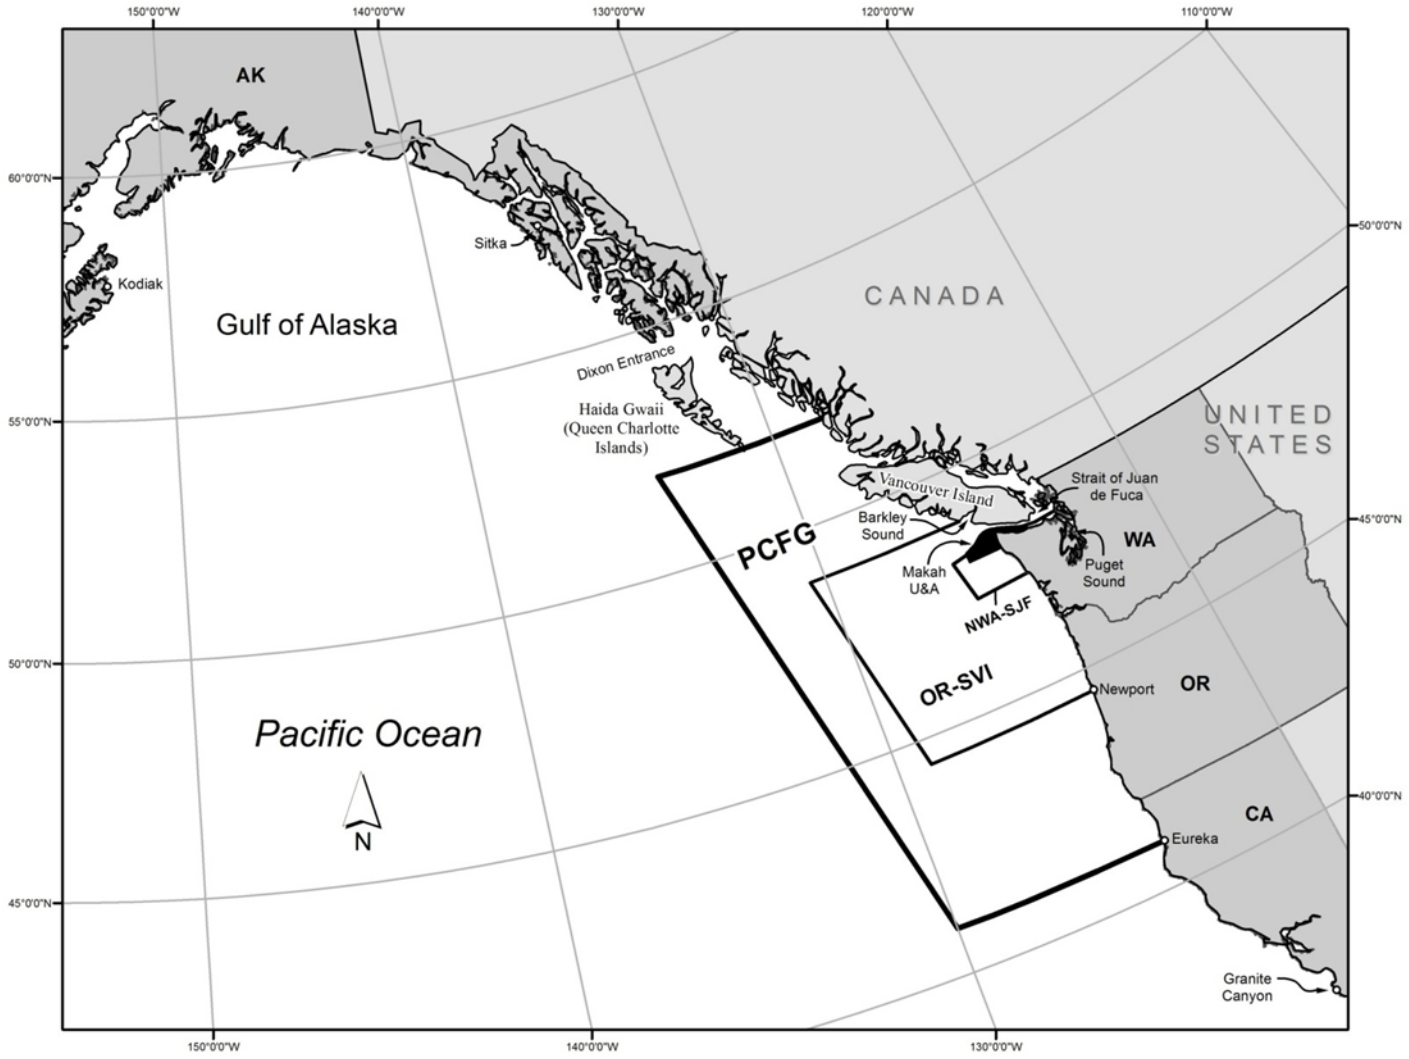

Figure 3-9. Spatial scales associated with the action area; PCFG, OR-SVI, and NWA-SJF (including the Makah U&A) survey areas.

Scientists have continued to research the PCFG and have obtained photographic identifications of 2,125 unique[32] whales from 1996-2020 that have been identified from southern California to Kodiak, Alaska. From photographs taken during the 22-year period from 1999 (when photo-ID effort expanded to cover all survey regions) to 2020, scientists identified 168 unique whales per year on average (ranging from 120 to 232) (Table 3-8). Prior to 2020, a cumulative total of 888 unique whales[33] were identified at least once in the PCFG seasonal range (i.e., June 1 to November 30 between northern California and northern British Columbia) (Figure 3-10a). Of those 888 whales, approximately 47 percent were identified at least twice in the PCFG seasonal range (Harris et al. 2022) (Figure 3-10b). As noted previously, whales seen within the PCFG range have also been sighted elsewhere. While some individuals return to the same general feeding area in some years, photo-identification studies have captured the large-scale movements and variability in the distribution of gray whales within seasons and between years.

[32] A 'unique whale' or 'identified whale' is an individual gray whale that has been identified from photographs and cataloged using a code unique to that animal (e.g., whale #1045 in the Cascadia Research Collective catalog would be coded "CRC 1045").

[33] The Cascadia Research Collective's database includes gray whale sightings from as far back as 1977. However, the data analyzed here focuses on the 888 identified whales sighted during the 1996 to 2019 time period during which there were more consistent and collaborative surveys, and some analyses focus on a subset of those years (1999 to 2019) to account for re-sightings and improved population modeling characteristics (see Harris et al. 2022).

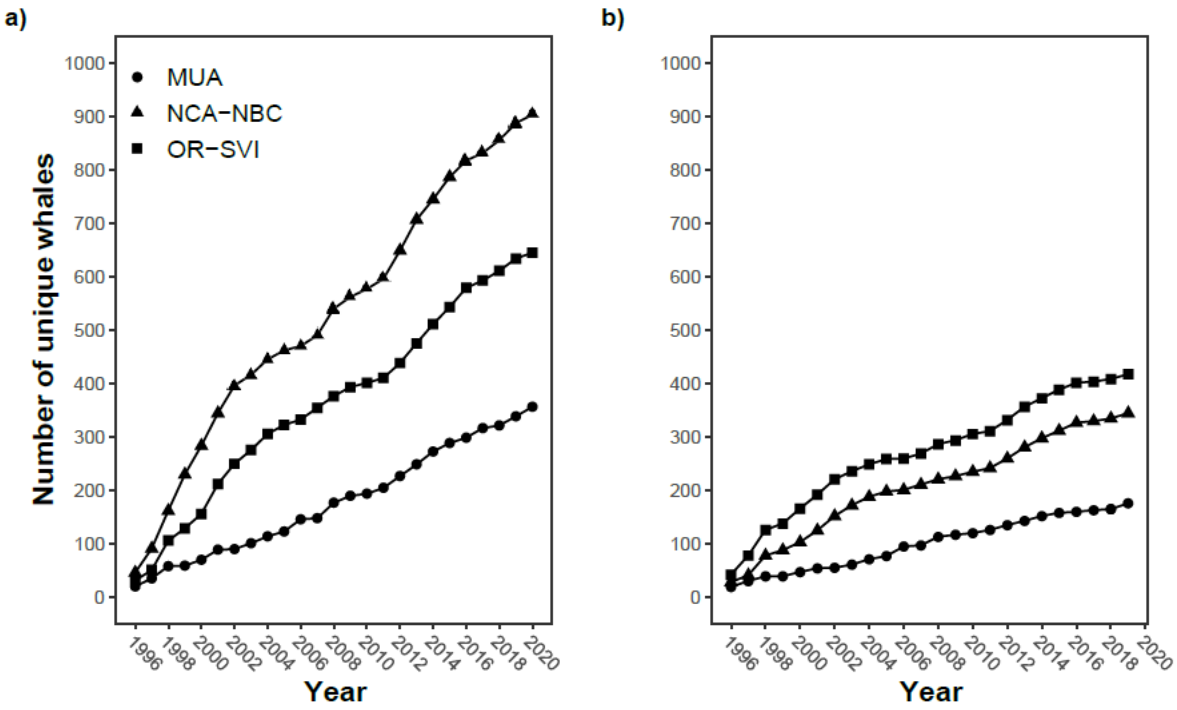

Figure 3-10. Cumulative number of unique gray whales photo-identified between 1 June and 30 November in at least one year (a) or more than one year (those meeting the definition of a PCFG) (b) in the Makah U&A, PCFG (NCA-NBC), and OR-SVI survey regions from 1996 to 2020 (figure from Harris et al. 2022).

Use of PCFG Survey Areas by Individual Whales

Of the 904 whales identified in the PCFG seasonal range from 1996-2020, 888 animals were first seen prior to 2020 (and so had the opportunity to be seen at least twice) (Harris et al. 2022). Approximately 53 percent of these animals (471 whales) have never been re-sighted, which demonstrates that many of the newly seen whales did not return in a subsequent year. However, a number of whales have been sighted during the summer in the PCFG range in each consecutive year after their first sighting. For example, as reported by Calambokidis et al. (2019), 6.4 percent (53 whales) of the 822 whales seen before 2017 were seen in every summer after their initial identification, including 4 whales that were seen in all 22 years from 1996-2017. Fifty-two percent were seen in only one year, and the remaining 41 percent (337 whales) were seen more than once but not in every year.

Many whales have an intermittent sighting history, some of which may be explained by sightings in areas adjacent to the PCFG range. For example, some whales were seen in Kodiak and southeast Alaska in years that they were not seen in the PCFG range (Calambokidis et al. 2014; Calambokidis et al. 2019). Of the 26 whales identified in southeast Alaska and the 153 whales identified in Kodiak, Alaska (in Calambokidis et al. 2019), 15 whales (57.7 percent) and 24

whales (15.7 percent), respectively, have been seen farther south in the PCFG range. For example, whale ID#130 was only seen in southeast Alaska in 1999 but was seen in all other years in the PCFG range. Likewise, whale ID#232 was only seen in Kodiak in 2002 but was seen along Vancouver Island in 2000, 2001, and 2003 and then wasn't seen again until 2011 and may have been somewhere in Alaska waters. Whale ID#152 was photo-identified in Kodiak in 2002, 2005, and 2010, but was seen in the PCFG range as early as 1995 in the Cape Caution, British Columbia area, and in 1992 in the Clayoquot Sound, British Columbia survey area. It has not been seen in the PCFG range since 1999 when it was seen along the west coast of Vancouver Island. Another example is Whale ID#68, seen in northern Washington during 1996 and 1997 and in southeast Alaska in 1998 and 1999 but not subsequently. Gosho et al. (2011) suspected that the movements within and between Kodiak and the PCFG areas to the south are likely driven by food availability and noted that the areas off Ugak Bay are thought to be the deepest foraging locations for gray whales south of the Bering Sea. While these are only a few examples of whale movements, they illustrate the extensive inter-year movement of whales, which partially explains the gaps in the observations for some whales and the disappearance of others from the PCFG. It is clear that many whales, both PCFG and non-PCFG whales, are only in the PCFG area temporarily and some whales (non-PCFG whales) only use it in a single year.

Whales seen in the PCFG range exhibited a wide range of movement across and within years. The 151 whales seen in 9 or more years (Calambokidis et al. 2019) provide a useful example. None of those whales was seen exclusively in a single survey region, and 68.2 percent were seen in at least four of the nine survey areas from 1996 to 2017. However, whales did regularly visit the same regions across years, with 95.4 percent seen in at least one of the regions during 6 or more of the years they were seen. Of the 151 whales, 58.3 percent were seen in a particular region two-thirds or more of the years they were seen. Southern Vancouver Island (SVI) was the region with the maximum number of years seen for 66 of the 151 whales, which in part reflects the larger amount of survey effort in SVI (Calambokidis et al. 2004a; Calambokidis et al. 2014; Calambokidis et al. 2019). Thus, some whales regularly visit particular regions, but they use other regions as well. Calambokidis et al. (2004a) and Calambokidis et al. (2014) also showed that whales seen in more years appeared in more regions.

Within-season movement of photo-identified and re-sighted whales in the summer feeding period can be extensive (Calambokidis et al. 2014; Calambokidis et al. 2017; Calambokidis et al. 2019). For each survey area examined, movements were greatest between adjacent areas with less movement to distant areas (Calambokidis et al. 1999; Calambokidis et al. 2004a; Calambokidis et

al. 2014; Calambokidis et al. 2017; Calambokidis et al. 2019). This pattern demonstrates that whales do focus on specific areas within the summer season, but they will move in search of food, most likely to neighboring areas. For example, over a 22 year span (1996 to 2017), 52.8 percent of whales with six or more sighting days had a primary range of >60 nautical miles (one degree of latitude) (Calambokidis et al. 2019), suggesting a lack of site fidelity among most PCFG whales. There have been examples of large-scale movements within a year. One whale, originally photo-identified in a southeastern Alaska survey area around September 1999, was re-sighted far south about a month later in a northern California survey area (Calambokidis et al. 2004a). Another whale moved in the opposite direction; researchers originally identified it off southern Vancouver Island during June-July 2003, it swam at least 1,104 nautical miles (2,045 km) in 34 days or less and reappeared off Kodiak on August 9, 2003 (Calambokidis et al. 2004a). Within-season and between-year movements of gray whales likely relate to changes in productivity and prey availability. Darling et al. (1998), for example, noted a long-term change in the use of the Wickaninnish Bay survey area off the central west coast of Vancouver Island, British Columbia. From 1966 to 1977, whales were consistently present from May to September, but use of the habitat during summer was becoming less consistent by 1977. Since 1989, gray whales have been observed feeding mostly on pelagic prey (e.g., crab larvae and swarming amphipods), although occasional bouts of benthic feeding also occurred throughout this time, such as in April 1996 (Darling et al. 1998). Scordino et al. (2014a) reported fewer gray whale sightings in the Makah U&A in June (compared to later in the summer and fall) and noted that those observations, along with available information on movements of satellite-tagged PCFG whales, suggests the possibility that whales who feed in the PCFG range may feed further north (e.g., off Alaska) in the spring and early summer before heading south to the PCFG feeding grounds later in the year.

Similar findings of variable whale movements were reported by Scordino et al. (2011a) during research surveys conducted by the NMML and the Makah Tribe within the Makah U&A during summer and fall 1993 to 2009. Researchers assessed the site fidelity of individual whales by examining minimum residency time and annual capture histories from photographs. These researchers observed that, on average, individual whales using the Makah U&A are observed for a small portion of the June to November feeding season. Most gray whales were seen in only 1 year, and individuals sighted in multiple years averaged periods of 2.2 years between sightings in the Makah U&A. The sighting histories of individual whales did not suggest that gray whales exclusively use the Makah U&A during the summer/fall feeding season. Scordino et al. (2011a) concluded that their results suggest that most gray whales sighted in the Makah U&A do not have

strong fidelity to this area. Calambokidis et al. (2019) found that of the whales sighted in regions from NCA to NBC, from 45.1 to 63.5 percent of whales, depending on the region, seen in at least 1 year were seen at some point within the Makah U&A; 52.6 to 82.5 percent of the whales seen in at least *2 years* were seen at some point within the Makah U&A.

In summary, sightings and photo-identification data show a continuum of gray whale distribution in the PCFG area during the summer and fall feeding periods from at least the southernmost survey area in northern California to northern British Columbia, and possibly further north to Southeast Alaska (near Sitka) and Kodiak Island (Calambokidis et al. 2003; Calambokidis 2004a; Moore et al. 2007; Gosho et al. 2011; Calambokidis et al. 2014; Calambokidis et al. 2017; Calambokidis et al. 2019; Harris et al. 2022) and south to central and southern California. Although some gray whales return to the same general feeding area in at least some later years, photo-identification data have demonstrated large-scale movements and variability in gray whale distribution and habitat use within season and between years. These movements and variability are likely due to shifts in prey availability, the opportunistic and diverse nature of the species' feeding ecology (Subsection 3.4.3.1.4, Feeding Ecology and Role in the Marine Ecosystem), and the ability of gray whales to respond rapidly to changes in prey and to explore alternate feeding areas throughout their range (Darling et al. 1998; Dunham and Duffus 2001; Moore et al. 2003; Moore 2005; Moore et al. 2007). This flexibility, coupled with the location of the PCFG area in the midst of the migration route for the entire ENP herd, provides an obvious and natural mechanism for new whales to join the PCFG. However, the evidence for maternally directed site fidelity and the regular, annual return of specific whales to the PCFG underscores the complexity of recruitment processes supporting this feeding aggregation of gray whales.

Proportion of PCFG Whales Sighted in the Makah U&A During the Tribe's Proposed Hunt Period (December 1 to May 31)

In addition to surveying for and photographing whales during the summer feeding period, researchers have also surveyed for and photographed whales during the winter and spring migration period. Although there are far fewer sightings in the coastal portion of the Makah U&A (NWA; see Figure 3-8) during the migration period than during the summer feeding period, there are sufficient data to allow us to estimate the likelihood that Makah hunters would encounter a PCFG whale during a winter or spring hunt in the NWA. The proposed hunt may occur in the NWA after November 30 and prior to June 1. Based on the analysis of Calambokidis et al. (2019), a hunt conducted in spring (March to May) potentially could take whales from the PCFG (although those chances are less in the NWA than in the Strait of Juan de Fuca portion of the

Makah U&A). There have been 359 whale sightings[34] in the NWA prior to June 1 (i.e., December 1 to May 31), of which 27.3 percent (98) were whales that were seen in the PCFG range at some time after June 1, 26.2 percent (94) were of whales that were seen in OR-SVI areas at some time after June 1, and 23.4 percent (84) were of whales that were seen in the Makah U&A area at some time after June 1. In comparison, there were 99 whale sightings in the Strait of Juan de Fuca (SJF) area prior to June 1 (i.e., December 1 to May 31), of which 60 percent (55) were of whales that were seen in the PCFG range after June 1 at some time, emphasizing the importance of restricting a hunt to coastal waters of the Makah U&A (i.e., the NWA) to limit the take of whales from the PCFG. Scordino et al. (2013) also analyzed the proportion of PCFG whales sighted in the SJF and NWA survey areas from December through May (the proposed winter/spring hunting season) and found that 31 percent of sightings in the NWA were PCFG whales. Weather conditions are less favorable for surveys during December through February, and the few whales sighted (less than 5 whales during the 1996-2011 timeframe (Scordino et al. 2013)) prevent making informed estimates of the proportion of PCFG whales present during the winter months.

Distribution of PCFG Whales Relative to Shore

Various studies have assessed gray whale distribution relative to shore during the typical winter/spring migration periods of the ENP gray whale population, and those are included in Subsection 3.4.3.3.1, ENP Seasonal Distribution, Migration, and Movements. General descriptions of coastal sightings in the PCFG range can be found in many of those studies and related reports (e.g., Pike 1962; Patten and Samaras 1977; Calambokidis et al. 1997); specific sighting locations relative to shore are not always reported. Relatedly, opportunistic sightings from whale watching operations (charter boat, air services, and shore-based sites/programs) operating throughout the PCFG range are not typically reported in the published literature. The "Whale Watching Spoken Here" program in Oregon (Oregon Parks and Recreation Department 2013) is one exception. This program posts sightings data online and notes that "summer feeding whales [approximately 200-400 animals] are very close to shore." The following examples from studies published during the past 30 years use maps or cite specific locations/distances from shore to report on gray whale sightings in the PCFG range during the summer/fall:

- Hatler and Darling (1974) combined shipboard sightings and reports of earlier studies (1965 to 1973) to document sightings of gray whales (including mother-calf pairs) during

[34] These "sightings" include whales seen on multiple days.

the summer in the vicinity of Wickaninnish Bay, Vancouver Island, B.C. All sightings mapped in this study during the non-migration period were within 1.5 miles (2.4 km) of shore.

- Sumich (1984) used aerial and shore-based observations to document over 1,200 gray whale sightings (including calves) during the summer and within 0.3 miles (0.5 km) of the Oregon coast.
- Darling (1984) used direct observations and photo-identifications to document summer resident animals arriving off Vancouver Island as early as April 8 and departing the area as late as December 14. From 1975 to 1981, he sighted from 10 to 34 whales per year feeding during the summer along the coast of Vancouver Island and noted that all were seen within 0.6 miles (1 km) of the shore (most within 328 feet [100 m]), with some seen repeatedly feeding in protected waterways near Tofino, British Columbia.
- Mallonée (1991) reported 50 sightings of summering whales during shore-based observations off the northern California coast (1986 to 1988), noting that some whales could be seen milling in small, restricted areas approximately 0.03 to 0.3 miles (0.05 to 0.5 km) from rocky headlands, in the middle of bays, and at the mouth of the Klamath River.
- Brueggeman et al. (1992) used aerial and shipboard surveys to document 28 gray whale sightings during the summer and fall off the Washington and Oregon coasts, noting that all but one of the summer sightings occurred within bays or within 0.6 miles (1 km) of the coast.
- Calambokidis et al. (1997) observed gray whales over 31 miles (50 km) off the Vancouver Island coast and 28 to 56 miles (45 to 90 km) off the Washington coast during summer aerial surveys in 1997 (as cited in Shelden et al. 2000).
- Dunham and Duffus (2001) reported on dozens of sightings of gray whales foraging within 0.3 miles (0.5 km) of shore from June to September (1996 to 1997) in Clayoquot Sound, Vancouver Island, British Columbia.
- Calambokidis et al. (2004b) documented the presence of 7 gray whales in 5 locations off the Washington coast, averaging 3.1 miles (5 km) from shore in 66 feet (20 m) of water during shipboard surveys conducted in the Olympic Coast National Marine Sanctuary during the summer (1996 through 1998).
- Calambokidis et al. (2009a) observed unusual clusterings of gray whales during shipboard surveys from June to September, 2007, in two areas: one in and around the entrance to Grays Harbor, Washington, and another 12 to 16 miles (20 to 25 km) offshore

in waters nearly 200 feet (60 m) deep. The offshore sightings consisted almost exclusively of animals previously identified during the summer in other areas of the Pacific Northwest.

- Scordino et al. (2011a) sighted 189 unique gray whales during summer/fall boat-based surveys conducted between 1993 and 2009 in the Makah U&A. Most gray whale sightings occurred in waters between 26 and 49 feet (8 and 15 m) deep in areas that are characterized by rocky substrate and kelp forests. These researchers speculated that the availability of a prey species (mysid shrimp) may greatly influence gray whale sightings in the area. They also noted that gray whales in the Makah U&A appear to shift from using coastal ocean areas (i.e., the proposed hunt area) in the summer to Strait of Juan de Fuca areas in the fall.

Sighting data collected by Cascadia Research Collective, NMML, and the Makah Tribe in the PCFG range (and the Makah U&A area within the PCFG range) indicate that the vast majority of whales in the proposed hunt area are located within 3.1 miles (5 km) of shore (Scordino et al. 2013; P. Gearin, NOAA Fisheries Research Biologist, pers. comm., May 5, 2014). The concentration of whales close to shore during the summer is not surprising given that PCFG gray whales are actively feeding and would tend to be found in shallower waters with close access to benthic prey as well as mysid shrimp concentrations (Dunham and Duffus 2001; Dunham and Duffus 2002). However, most of the survey effort is also concentrated in nearshore areas and it is possible that surveyors do not see whales that are further offshore. As noted previously, Green et al. (1995) questioned the feasibility of conducting accurate shore-based gray whale censuses along the Oregon and Washington coasts given the high proportion of whales sighted beyond a shore-based observer's range of view.[35] Feeding season boat-based surveys in the Makah U&A are typically conducted within 1.2 miles (2.0 km) of shore because gray whales that summer in the area often congregate around 33 feet (10 m) of depth (Scordino et al. 2014a). These authors also documented whales feeding in deeper waters (98 to 115 feet/30 to 35 m) and gray whales are reported to feed in waters as deep as 164 to 200 feet (50 to 60 m) deep (Jones and Swartz 1984); in the coastal portion of the Makah U&A, such depths extend offshore as far as 9 miles (15 km). Migratory season surveys in the Makah U&A are generally conducted within 3.1 miles (5 km) of

[35] Shelden and Laake (2002) estimated that 3.5 miles (5.6 km) was the expected outer viewing limit of shore-based observers at a gray whale counting station near Granite Canyon, CA. Similarly, Sumich (1984) considered 3.1 miles (5 km) as the practical maximum distance that gray whales could be reliably seen with binoculars under ideal conditions.

shore but since 2009 have extended as far offshore as 5 to 6.2 miles (8 to 10 km) (Scordino et al. 2013).

In summary, gray whales found in the PCFG range (including the Makah U&A) during the summer/fall are most likely to be found in relatively shallow coastal waters, usually within 3.1 miles (5 km) of shore. Seasonal and year-to-year variability in prey or ocean conditions likely have a great influence on the species' distribution. Gray whales using waters far offshore are probably much less common (e.g., because of the greater diving depths required to pursue benthic prey) and largely undetected given existing survey methods.

3.4.3.4.3 PCFG Abundance and Trends

From the preceding sections it is apparent that the PCFG does not exhibit traits of a completely closed population whose abundance fluctuates solely based on births and deaths of member animals and not on migration into or out of the population. Instead, it appears to have complicated dynamics that likely includes whales with the following characteristics:

- Whales that use the PCFG range[36] based on learning "local knowledge" from their mothers.
- Whales that use the PCFG range on an almost annual basis.
- Whales that use the PCFG range intermittently over the years.
- Whales that used the PCFG range once but never returned (i.e., transients).
- Whales that use the PCFG range for long periods of time in a given season.
- Whales that use the PCFG range for short periods of time in a given season.
- Whales that use large expanses of the PCFG range in a given season.
- Whales that use small expanses of the PCFG range in a given season.
- Whales that travel in and out of the PCFG range in a given season.
- Whales that use the PCFG range but are not sighted (e.g., they occur in areas not surveyed or are otherwise missed by surveyors).

A particular whale may exhibit several of these characteristics during its lifetime. It is also likely that, in any given year, the assemblage of whales found in the PCFG range exhibit all of these characteristics, thereby underscoring the difficulty in deriving an accurate abundance estimates for the PCFG. Nearly 20 years ago, Darling (1984) made a rough estimate that in addition to 35 to

[36] In this list, "PCFG range" refers to the area bounded by 41° N to 52° N (i.e., from survey areas NCA to NBC) and "season" refers to the period June 1 to November 30.

50 whales off Vancouver Island, "[a]pproximately 75 whales summer off Oregon each year (B.R. Mate [Oregon State University], pers. comm., 1979), so it is likely there are at least 100 in the British Columbia-Washington-Oregon area." Since then, it has become possible to develop more refined estimates using mathematical models referred to as 'mark-recapture' estimators based on the photo-identification data collected annually in the range of the PCFG during June 1 to November 30. Since 1977, these data presently identify 888 gray whales that have been seen at least once in the range of the PCFG during June 1 to November 30 and assigned unique identification numbers in the Cascadia catalog. Of these, approximately half have been seen two or more times and therefore fit the definition for the PCFG (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements).

Calambokidis et al. (2004a) first proposed that it was more appropriate to use open population models than closed population models to estimate abundance of gray whales in the PCFG and OR-SVI survey areas. Because new whales are entering a given area each year (gains through immigration and recruitment) and some new whales never return (losses through emigration and death), closed population models produce biased estimates that make them less suitable for the dynamics exhibited by PCFG whales.

More recent modeling has confirmed this conclusion. Calambokidis et al. (2012) used a variety of open- and closed-population estimators to calculate the annual abundance of PCFG whales. They concluded that the traditional Lincoln-Petersen estimator based on a closed population was positively biased because of transient whales passing through each year. The bias was greatest during the early part of the time series with greater numbers of transients in 1999 to 2001 during and after the 1999 to 2000 stranding event. The other estimators attempted to cope with the transient whales to estimate the abundance of whales excluding the transients. The trends from those estimators all showed an increase from 1998. Calambokidis et al. (2012) concluded that the modified Jolly-Seber model (referred to as 'JS1') was the least biased and best estimator for the PCFG. The JS1 estimator for each year is composed of an estimate of the number of previously seen (marked) whales that remain (alive and have not permanently emigrated) in the population plus an estimate of the number of newly seen whales that are expected to return based on their estimated first-year apparent survival, which is dominated by emigration as a result of transience. In the first year of the study (e.g., 1998 in Calambokidis et al. 2012), there are no previously seen whales so the initial estimate will be biased low. With simulation and an analysis that included some data from 1996 and 1997, Laake (2012) concluded that most of the bias was in the 1998 estimate.

Table 3-7 and Figure 3-11 display the abundance estimates from the most recent analysis by the Cascadia Research Collective and NMFS' Alaska Fisheries Science Center (Harris et al. 2022). The models indicate that the PCFG grew significantly from 39 animals identified in 1996 to 212 animals in 2020. The overall PCFG population has been stable over the last 20 years, declining slightly in recent years from a peak in 2015 (Harris et al. 2022) (Figure 3-11).

However, abundance in both 1996 and 1997 are likely even lower than estimated because the photographic effort was not as expansive as after that period; thus, the increase from 1996 to 1998 is inflated. As noted previously, each year's estimate includes a mix of whales that have either been previously seen using the area or have been seen using it for the first time and are expected to return and use it again. For comparison with the model-derived estimates, the most recent photo-identification data on gray whales (Harris et al. 2022) in the PCFG seasonal range show that the number of uniquely identified whales sighted in a given year has ranged from 45 whales in 1996 to a high of 232 whales in 2013, and 163 whales in 2020.[37]

Table 3-7. Model-averaged abundance estimates (N) and minimum abundance estimates (Nmin) for PCFG gray whales based on sightings in the PCFG, OR-SVI, and Makah U&A survey regions (Harris et al. 2022).

Year	PCFG (NCA-NBC)		OR-SVI		Makah U&A	
	N	Nmin	N	Nmin	N	Nmin
1996	39	37	25	23	17.7	16.6
1997	81	73	46	41	32.4	28.6
1998	133	122	94	87	43.5	35.5
1999	145	133	82	76	42.8	31.0
2000	147	136	86	79	36.0	21.9
2001	182	171	156	147	54.4	43.7
2002	210	191	128	120	46.1	30.9
2003	209	196	169	159	55.1	42.0
2004	224	208	159	150	58.2	44.9
2005	208	184	170	160	64.2	54.0
2006	195	178	152	143	74.0	66.2
2007	185	163	173	162	79.7	62.4
2008	217	202	199	188	90.8	83.2
2009	208	191	165	156	94.6	83.6
2010	201	186	144	135	98.7	79.1

[37] Calambokidis et al. periodically update their analyses via reports that use the most recent sighting data available as well as corrections (e.g., because of identification errors) to data reported in previous years' reports. For example, Calambokidis et al. (2012) reported 130 PCFG whales sighted in 1998 while Calambokidis et al. (2014) corrected that value to 132 whales.

2011	213	200	140	131	94.5	79.5
2012	229	215	181	171	105.7	94.2
2013	249	235	194	185	108.8	96.4
2014	245	230	210	199	115.8	101.0

N = Population size estimate; Nmin = Minimum population size estimate

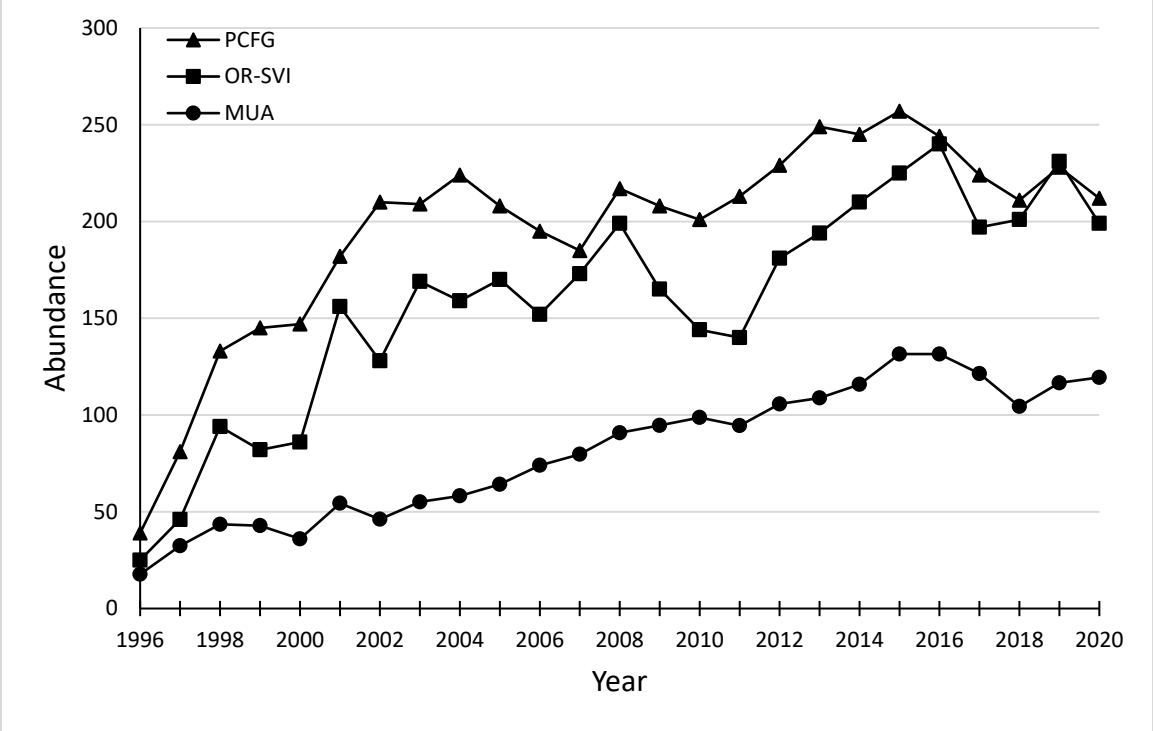

Figure 3-11. Model-averaged abundance estimates for PCFG gray whales based on sightings in the PCFG, OR-SVI, and Makah U&A survey regions from 1996 to 2020 (data from Harris et al. 2022).

The granularity of the data analyzed by Harris et al. (2022) provides insight into the abundance of gray whales utilizing the whole PCFG range and smaller areas within it. Tables 3-4 through 3-6 summarize the trends throughout the range and within the Oregon to Southern Vancouver Island (OR-SVI) region and the Makah U&A. From June 1 to November 30 for the primary sampling

period of 1996 to 2020, 904 unique ENP gray whales were seen in the PCFG range; their related sighting data is shown in Table 3-8. Approximately 71 percent (645 of the 904 whales seen) were seen within the smaller OR-SVI region (Table 3-9), and about 39 percent (356 of the 904 whales seen) were seen within the even smaller Makah U&A region (Table 3-10). These tables also show the annual average number of whales identified, which was 158, 112, and 39 in the PCFG, OR-SVI, and Makah U&A survey regions, respectively. However, those numbers do not represent the total numbers of whales that use each of these survey regions because not all whales present in a survey region in a year are seen, not all whales return to the same survey region each year, and not all of the whales return to the PCFG region each year. The annual average number of newly seen whales (excluding years prior to 1999, when the photo-identification effort expanded to cover all survey areas) was 34, 25, and 14 for the PCFG, OR-SVI, and Makah U&A survey regions, respectively. The annual average number of newly seen whales that were seen again in a subsequent year, excluding 1996 to 1998 and 2020, was 14, 13, and 7 for PCFG, OR-SVI, and Makah U&A survey regions, respectively. Thus, a substantial number of new whales were seen each year, and 40, 51, and 49 percent of those were seen again in a subsequent year in the PCFG, OR-SVI, and Makah U&A survey regions, respectively.

The plots shown in Figure 3-10a and 10b display the cumulative number of unique whales identified by Harris et al. (2022) for the PCFG, OR-SVI, and Makah U&A survey regions. The plots (typically called “discovery curves”) demonstrate that the PCFG is not a closed population because all of these curves continue to climb due to new individuals seen each year (31 non-calf whales per year on average from 1999-2020 in the PCFG range) and at a rate that exceeds the number of new calves seen each year (approximately 5 per year from 1999-2020 in the PCFG range). As noted in Subsection 3.4.3.4.1, PCFG Population Structure, calf estimates could possibly be higher because some of the new whales may have entered the PCFG earlier as a calf and were not seen or identified as such, or used other feeding areas during their first several years. Regardless, the large disparity between calf and non-calf sightings makes it most plausible that the majority of non-calf animals sighted in a given year are immigrants to the PCFG (and subregions within). The same pattern is true for whales that are sighted in more than one year (Figure 3-10b).

Table 3-8. Classification of whales seen within the PCFG (Northern California to Northern British Columbia) from June 1 to November 30 from 1996 to 2020.

Estimating Numbers of Whales for Subregions Within the PCFG Range

OR-SVI. Darling (1984) estimated 35 to 50 gray whales for Vancouver Island and 100 whales for the Pacific Northwest. In deriving the estimates, he defined abundance as the number of gray whales found in the study sites in any particular year. Calambokidis et al. (2004a) proposed that the appropriate method of estimating abundance was to consider the total number of identified whales observed in a given area and that the area most appropriate for managing a Makah gray whale hunt was the survey areas from Oregon to Southern Vancouver Island (OR-SVI). To reach this conclusion, they focused on whales identified in the survey areas corresponding to the entire Makah U&A (which is encompassed in the northern Washington coast and Strait of Juan de Fuca survey areas). Calambokidis et al. (2004a) examined the degree to which whales sighted in these survey areas were also sighted in the OR-SVI and PCFG survey areas (Figure 3-9). Of the whales seen in the PCFG survey area during the 6 years of their study, 30 percent were also seen in the entire Makah U&A (within the northern Washington coast and Strait of Juan de Fuca survey areas; Figure 3-9). In contrast, more than half the whales seen in the OR-SVI survey area during the study were also seen in the entire Makah U&A. Based on the relatively high rate of interchange between the OR-SVI and the entire Makah U&A compared to the rate of interchange between the PCFG and the entire Makah U&A, Calambokidis et al. (2004a) concluded that "it is both logical and reasonable to use OR-SVI as the region for abundance estimation in setting quotas for a harvest of whales from the [Makah U&A] region."

The Makah Tribe's proposal includes a provision that would limit unintentional harvests of PCFG whales by setting a harvest limit. Under the proposal, the limit would be set using a formula based on the subset of PCFG whales that exhibit site fidelity to survey areas from Oregon to Southern Vancouver Island (OR-SVI). The basis for selecting this region was the recommendation by Calambokidis et al. (2004a) that the OR-SVI was a logical and reasonable management area for considering impacts from gray whale harvests in the Makah U&A (see above). Support for this recommendation is also found in the report by Calambokidis et al. (2014) that analyzed sighting data for whales seen relatively frequently (i.e., seen on at least 6 different days) in the PCFG range from June 1 through November 30. Based on the observed clustering of those sightings, these researchers concluded that "it makes little sense to compute an estimate of abundance for any region that spans less than a degree of latitude" (approximately 69 miles [111 km]). The OR-SVI region spans approximately 4 degrees of latitude.

In addition to the conservative approach of a harvest limit based on a smaller area/number of whales than the entire PCFG, the formula relies on a *minimum* abundance estimate (rather than the higher average) of whales using this area. Calambokidis et al. (2014) calculated estimates for OR-SVI whales using the estimators described in Subsection 3.4.3.4.3, PCFG Abundance Trends. The JS1 estimator produced abundance estimates for OR-SVI that were expectedly lower than PCFG values but followed a trajectory very similar to that of the PCFG estimates, a pattern that holds true with more recent data as well (Harris et al. 2022). The current OR-SVI estimates increase from approximately 25 animals in 1996 to 240 animals in 2016, with the most recent estimate somewhat lower at approximately 199 whales in 2020 (Table 3-7). Based on the data in Harris et al. (2022), minimum population estimates for the OR-SVI are, on average, about 6 percent lower than the abundance estimates, with the most recent (2020) Nmin estimated at 190 animals (Table 3-7). The most recent photo-identification data on gray whales (Harris et al. 2022) in the OR-SVI from June 1 through November 30 show that the number of uniquely identified whales sighted in a given year has averaged 112, ranging from 30 (in 1996) to 176 (in 2016); the most recent number identified was 141 whales in 2020 (Table 3-9).

Makah U&A. As noted in Subsection 1.1.2, Makah Tribe's Proposed Hunt Location, the action area includes the Makah U&A which is within the NWA and SJF survey areas. Although all of the alternatives restrict hunting to the coastal portion of the Tribe's U&A (i.e., only within the NWA survey area), our analyses of all alternatives considers whales that use both the NWA and SJF portions of the Tribe's U&A. This is because of the close proximity of the NWA and SJF and evidence that whales using one area frequently occur in the other. Therefore, a decrease in whales using the NWA could also result in a decrease in whales using the SJF. The NWA-SJF (including the Makah U&A) survey area spans less than 1 degree of latitude, and Calambokidis et al. (2014) conditioned their estimates by noting that "this area is quite small relative to the observed movements of whales within the PCFG."

The JS1 estimator produced estimates for the number of PCFG whales sighted in the Makah U&A survey region between June 1 and November 30 that were expectedly lower than PCFG and OR-SVI values and followed an increasing trajectory that was similar to, but flatter than, the trends for PCFG and OR-SVI estimates. The Makah U&A abundance estimates increased from approximately 18 animals in 1996 to 132 animals in 2015-2016, with the most recent estimates somewhat lower at approximately 119 whales in 2020 (Table 3-7). Based on the data in Harris et al. (2022), minimum population estimates for the Makah U&A are typically about 18 percent lower than the average estimates, with the most recent (2020) Nmin estimated at 104 animals

(Table 3-7). The most recent photo-identification data on gray whales (Harris et al. 2022) in the Makah U&A from June 1 to November 30 show that the number of uniquely identified whales sighted in a given year has averaged 39 and ranged from 8 (in 2002) to 75 (in 2008) (Table 3-10).

3.4.3.4.4 PCFG Status, Carrying Capacity, and Related Estimates

It is difficult to compare the past and present status of the PCFG given that we know little about these whales historically. Scordino et al. (2011b) reviewed the available literature regarding the PCFG and concluded that it is unclear whether the PCFG existed prior to the 20th century. Alter et al. (2012) conducted genetic analyses of modern and ancient gray whale bones, including archaeological samples from the Makah U&A/PCFG range. Overall, their analysis supported the hypothesis that gray whales experienced a major population decline and the possibility that there was population substructure in the past in the vicinity of the Olympic Peninsula and Vancouver Island. However, these authors noted that it was premature to draw firm conclusions about such structure given the small sample sizes and small differences observed.

During the past century, the ENP gray whale population—including the PCFG—has rebounded from as few as 1,500 animals (Butterworth et al. 2002) to over 20,000 whales in recent years and was removed from the federal ESA list of endangered and threatened wildlife in 1994 (59 FR 21094, June 16, 1994). In 2010, WDFW was petitioned to list the "Eastern North Pacific – Southern Group" of gray whales as endangered under Washington Administrative Code 232-12-297 (WAC). WDFW denied the petition, noting that gray whales are presently listed by the state as a sensitive species, but that the WAC does not allow for listing populations or subpopulations of species or subspecies (Anderson 2010).

Currently, the IWC has concluded that it is plausible that the PCFG is a demographically distinct feeding group (IWC 2010a) and has assessed the potential harvest-related impacts on this group of whales from the Tribe's proposed hunt as set forth in Alternative 2 (refer to IWC Implementation Review of PCFG Gray Whales, below)[50]. Similarly, we have determined that the PCFG may warrant consideration as a separate stock in the future, and in our most recent stock assessment report calculated a separate, informational PBR level for the PCFG to assess whether levels of human-caused mortality are likely to cause local depletion of this group (Carretta et al. 2023). This calculation used a minimum population size (Nmin) of 227 animals, times one half

[50] Although the IWC has not identified the PCFG as a stock, the Scientific Committee (IWC 2012a) noted that its Implementation Review of eastern North Pacific gray whales (with an emphasis on the PCFG) was "based on treating PCFG as a separate management stock" (which may not be equivalent to a stock as defined under the MMPA).

the maximum theoretical net population growth rate (Rmax; ½ x 6.2 percent = 3.1 percent), times a recovery factor of 0.5, resulting in a PBR of 3.5 animals per year (Carretta et al. 2023) (Table 3-11). Estimates of human-caused mortality in the PCFG between 2014 and 2018 averaged 1.7 whales per year (Carretta et al. 2023). Applying the same recovery factor and Rmax value but using the most recent Nmin estimate of 198 animals (Harris et al. 2022), yields a similar PBR of 3.1 animals per year.

Punt and Moore (2013) attempted to determine the OSP level for the PCFG using an existing population dynamics model employed by the IWC. After running 13 model variants, they concluded that "it was not possible to draw a definitive conclusion as to whether the PCFG is within OSP." They noted that the equivocal outcome of their analysis largely stems from the relatively flat, stable abundance data available for the PCFG. One possible explanation for their finding is that the PCFG is at or near its carrying capacity and, thus, above MNPL and within OSP. Given different potential rates of intrinsic population growth, it is possible the PCFG area could support more whales and that current numbers are regulated by a combination of bycatch mortality and emigration that offsets internal production (recruitment of calves born to known PCFG females) and immigration. Punt and Moore (2013) suggested that obtaining better estimates of a number of model parameters could potentially improve assessments of whether the PCFG is within OSP.

IWC Implementation Review of PCFG Gray Whales

Subsection 3.4.3.3.4, ENP Status, Carrying Capacity, and Related Estimates—IWC Implementation Review of ENP Gray Whales, provides an overview of the IWC's goals, objectives, and process for conducting an Implementation Review (i.e., a periodic evaluation of catch limits) for ENP gray whales, of which the PCFG are a part.

Over a decade ago during the IWC's development of a gray whale strike limit algorithm (SLA), there was discussion of stock structure at several meetings. While the possibility of a summer feeding aggregation along the Pacific coast between California and southeast Alaska was discussed, the Scientific Committee agreed in 2000 that a single ENP stock scenario was the most appropriate (IWC 2001). In 2010, the Committee was presented with findings from new genetic (Frasier et al. 2010), photo-identification (Calambokidis et al. 2010), and telemetry studies (Mate et al. 2010) and reached the conclusion that "[d]espite some differences in interpretation and recognizing that further analyses could be carried out, the [Standing Working Group] agreed that the hypothesis of demographically distinct southern feeding group [PCFG] is plausible and warranted further investigation" (IWC 2010a). At the 2010 annual meeting (IWC 2011a), the

Committee also determined that the just-completed 2010 Implementation Review had shown that the ENP population as a whole was in a healthy state and that the gray whale SLA could continue to be used to provide advice on the Russian (Chukotkan) hunt (refer to Subsection 3.4.3.3.4, ENP Status, Carrying Capacity, and Related Estimates—IWC Implementation Review of ENP Gray Whales). It further concluded that information reviewed on possible stock structure and the Makah hunt proposal (as set forth in Alternative 2) warranted a new Implementation Review to evaluate the performance of gray whale SLAs with a primary focus on the PCFG. That new review included various analyses and intersessional meetings in 2011 and 2012 wherein IWC scientists focused on building and evaluating an operating model and its associated trial structure.

At its 2012 meeting, the Committee announced that it had completed its new Implementation Review and had evaluated several variants of the proposed Makah hunt (IWC 2012e). These variants differed in the way that the Implementation Review handled bycatch of PCFG whales. Variants: (1) relied on an Allowable PCFG Limit (APL)[51] using the formula proposed by the Tribe in its application to NMFS (Makah Tribe 2005), (2) incorporated a fixed bycatch limit, or (3) explored no limit on bycatch of PCFG whales (the hunt is only stopped if the total strike limit is reached, or the number of struck-and-lost animals reaches its limit, or the landing limit is reached).[52] The trials tested within these variants were based on three hypotheses: 1) Hypothesis P (Pulse) assumed that there is no bias in the PCFG abundance estimates (but dropped the first year of estimates (1998)) and incorporated a pulse of immigration (1999-2000); 2) Hypothesis B (Bias) assumed a strong time-varying bias (dropped to zero in 2002) in the abundance estimate but no pulse of immigration; and 3) Hypothesis I (Intermediate) assumed a moderate time-varying bias in the abundance estimates and a pulse of 10 immigrants into the PCFG in both 1999 and 2000. These hypotheses were evaluated to account for difficulties in producing simulated abundance trajectories that fit the abundance estimates without incorporating a pulse or survey bias into their model. For these trials the IWC Scientific Committee agreed, based on the analysis by Laake (2011), that a reasonable estimate of annual immigration was up to six animals (IWC

[51] The APL is synonymous with the Allowable Bycatch Limit (ABL) proposed by the Tribe.

[52] The variants also differed from the Tribe's waiver application by including a presumption that some struck and lost whales would be PCFG whales. This condition was added for purposes of the Implementation Review modeling and articulated as follows: "A whale that is struck and lost between May 1 and May 31 will be presumed to be a member of the PCFG and will count toward the ABL for that calendar year unless photographs of the whale, when compared with the NMML-funded photo-identification catalogue maintained by Cascadia Research Collective, demonstrate that it is not a member of the PCFG" (IWC 2012e).

2012a; IWC 2012e). The Committee also included a robustness trial in which the future catch was strongly female biased (0.2 males:0.8 females).

The Committee noted that weather conditions and the availability of whales would make it likely that most hunting would occur in May but that data were insufficient to assess the number of strikes by month. Therefore, it was not possible to make a reliable estimate of the proportion of struck-and-lost whales that would count towards the APL. Given this uncertainty about how the planned hunt would respond to failing to take into account struck-and-lost PCFG whales, the Tribe had proposed two SLA variants spanning the options as to when the hunt might occur which were analyzed. These were:

- SLA variant 1: struck-and-lost whales do not count towards the APL; i.e., there is no management response to PCFG whales that are struck but not landed. This variant corresponds to the proposed hunt occurring entirely during December through April.
- SLA variant 2: all struck-and-lost whales count towards the APL irrespective of hunting month; i.e., the number of whales counted towards the APL may exceed the actual number of PCFG whales struck because some animals may not actually have been PCFG whales.

The Committee noted that SLA variants 1 and 2 were potentially satisfactory and performed well in nearly all 72 Evaluation Trials, and SLA variants 1 and 2 performed acceptably for all Robustness Trials. Variant 2 performed acceptably for all trials while Variant 1 performed acceptably for all trials except one, where it was deemed to have marginal performance. That trial assumes that the relative probability of harvesting a PCFG whale during December through May is double the observed proportion of PCFG whales in the available photo-identification studies during the corresponding time period. Specifically, the Committee stated that:

> "(1) SLA variant 2 performed acceptably and met the Commission's conservation objectives for conservation while allowing limited hunting;
>
> (2) SLA variant 1 performed acceptably for nearly all the trials and could be considered to meet the Commission's conservation objectives provided that it is accompanied by a photo-identification programme to monitor the relative probability of harvesting PCFG whales in the Makah U&A, and the results presented to the Scientific Committee for evaluation each year.

> The Committee endorses these conclusions and commends them to the Commission. It also agrees that the Implementation Review is completed."

The Committee also noted that while the SLA variants performed adequately for the trials in which the sex ratio of future catches is female-biased (0.2:0.8), the sex ratio of the hunt should be monitored and considered in future Implementation Reviews.

The IWC trials produce final statistics related to conservation status and catches, in particular an output termed the "final depletion level" which is defined by the IWC as the final population level as a percent of K.[53] For example, a trial that yields a final depletion level less than 0.6 (that is, 60 percent of K) would not be in accord with IWC conservation objectives. The Committee noted the poor performance/excessive depletion of some trials that included an assumption of low (1 to 2 percent) Maximum Sustainable Yield Rates (MSYR). However, they noted that such low rates were probably unrealistic given the evidence that the ENP population as a whole had recovered from severe historical depletion as a result of whaling and more recently rebounded from the 1999 to 2000 unusual mortality event. Therefore, the Committee concluded that the relatively poor results from these low-MSYR trials was not a reason to preclude the conclusion that both SLA variants had overall satisfactory conservation performance.

In the course of testing trials, the modeling conducted to assess SLAs generates thousands of estimates of K. The range of Ks fell between 161 and 1,000 animals and members of the SWG considered these values to be plausible for the sake of trial testing (A. Punt, Director, School of Aquatic and Fishery Science, University of Washington, pers. comm., May 15, 2013). However, the goal was not to pinpoint a specific value for K but instead to test a range of possible Ks (and numerous other parameters) to see how the final depletion levels were affected. Trial results that yielded depletion levels below 60 percent of a randomly chosen K estimate would be viewed as not meeting the IWC's conservation objectives.

Although these two variants were deemed acceptable, the Committee also noted that they did not correspond exactly to the hunt proposal submitted by the Makah Tribe (as set forth in Alternative

[53] Weller et al. (2013) note that this is related to, but can be slightly different from, the MMPA definition of "depletion," which is defined to be a population level below the Maximum Net Productivity Level (MNPL). In determining whether a stock is depleted under the MMPA, MNPL is generally assumed to either be a range from 50 to 70 percent of K, or a single value such as 50 percent or 60 percent of K. The only practical difference occurs when a range is used in MMPA determinations, where one calculates the probability a population is below MNPL over a range of percentages of K. If a single value is used for MNPL (e.g., 60 percent), then the IWC final depletion level is identical.

2) to the IWC and expressed concern that the actual conservation outcome of the proposed hunt was not tested. Essentially, the aspect of the proposed hunt that had not been evaluated was the interaction between the actual number of strikes-per-month during the December through May hunting season, and the assumption of whether a struck and lost whale belongs to the PCFG. The Committee agreed that the Standing Working Group of the AWMP should develop and test an exact variant intersessionally, in order to evaluate the results at the 2013 Annual Meeting.[54]

To address this issue, Brandon and Scordino (2012) submitted additional variants for testing that represented logical bounds on variants 1 and 2. Because there is no reliable way to predict the exact number (or model the probability) of strikes that may occur during a given month, they instead proposed to evaluate six additional variants representing each possible outcome of the number of strikes by month (during the December to May hunt period proposed by the Tribe):

A. Allow only one strike prior to May.
B. Allow two strikes prior to May.
C. Allow three strikes prior to May.
D. Allow four strikes prior to May.
E. Allow five strikes prior to May.
F. Allow six strikes prior to May.

At a December 2012 intersessional workshop (IWC 2012f), participants endorsed the testing of these new variants. After reviewing the results of these tests, the Scientific Committee noted that none of the new final depletion levels fell outside the bounds of those previously reviewed by the Committee and agreed that the proposed Makah hunt (as set forth in Alternative 2) had been fully examined within the SLA framework (IWC 2013a). Moreover, the Committee confirmed that the proposed management plan meets the IWC conservation objectives provided that if struck-and-lost whales are not proposed to be counted toward the APL, then a photo-identification research program to monitor the relative probability of harvesting PCFG whales in the Makah U&A is undertaken each year and the results presented to the Scientific Committee for evaluation. Only

[54] The IWC analysis used a 2010 OR-SVI minimum population estimate (Nmin) of 143 whales (as reported by Laake in the IWC 2012 AWMP Workshop Report), a recovery factor of 1.0, and a maximum net productivity rate (Rmax) of 4 percent. The Nmin estimate for OR-SVI whales is expected to vary (the current estimate is 152 animals (Calambokidis et al. 2014)), while values for Rmax and the recovery factor are fixed based on information submitted by the Makah Tribe to the IWC during the 2012 workshop focusing on PCFG gray whale Implementation Review. The 4 percent Rmax value used in that review was lower than the 4.7 percent used in the Tribe's application. We reviewed the differing values with the Tribe and determined that Alternative 2 (the Tribe's proposal) should be assessed using an Rmax of 4 percent in keeping with the analysis and findings of the IWC's Scientific Committee.

variant 2 meets the Commission's conservation objectives without the photo-identification research requirement. The Committee also noted that work was underway to further support such a research program via a photo-identification catalog managed by NMML.

In the 2020 Implementation Review, the Scientific Committee received updated abundance estimates for the PCFG through 2017, extending the time series that had been previously considered. The Scientific Committee agreed that the additional years of data did not alter their existing advice "with respect to the suitability of the either the Gray Whale SLA or the Makah Management Plan for the provision of advice on the Chukotkan and proposed Makah hunts" (IWC 2021b). In 2023, the Scientific Committee reviewed new information on ENP gray whale abundance and stock structure and concluded that the SLA and Makah Management Plan are robust to the current UME as well as future mortality events (Punt et al. 2023, IWC 2023a).

Table 3-11. Population estimates and limits for WNP, ENP, and PCFG gray whales.

Parameter	**WNP Stock**	**ENP Stock**	**PCFG**
Recent Abundance	290 whales (271-311) (Cooke 2017; Cooke et al. 2018)	14,526 whales (Eguchi et al. 2023a)	212 whales (Harris et al. 2022)
Minimum Population Estimate (N_{min})	271 whales (Cooke et al. 2017)	13,190 whales (Eguchi et al. 2023a)	198 whales (Harris et al. 2022)
Recent Trend	Increasing at 2-5 percent per year (Carretta et al. 2023)	Decreasing (Eguchi et al. 2023a)	Stable (Harris et al. 2022)
Recruitment	Average of 7 calves/year for 1997-2019; calf production index for 2019 = 6.9 percent (Burdin et al. 2019)	Calf production indices for 1993/94-2021/22 range between 1.3-6.8 percent (Eguchi et al. 2022b)	Average of 11.5 non-calf whales previously-seen-and-seen-again/year [range 1-28] + 3.4 calves seen/year [range 0-11] (Calambokidis et al. 2019)
Within OSP?	Not assessed (stock is listed as depleted under the MMPA)	No (based on Punt and Wade 2012); Yes (based on data in Stewart et al. 2023)[55]	Unknown (Punt and Moore 2013)
Recovery Factor (F_R)	0.1 (Carretta et al. 2023)	1.0 (Carretta et al. 2023)	0.5 (Carretta et al. 2023)
Maximum Net Productivity Rate (R_{MAX})	0.062 (Carretta et al. 2023)	0.062 (Carretta et al. 2023)	0.062 (Carretta et al. 2023)

[55] Punt and Wade (2012) estimated the 2009 population to be at 85 percent of carrying capacity (K) (posterior mean of 25,808) and at 129 percent of MNPL (see Subsections 3.4.3.3.4, ENP Status, Carrying Capacity, and Related Estimates). Based on data in Punt and Wade (2012), MNPL was approximately 16,000 whales at that time. This and the most recent abundance of gray whales (14,526) (Eguchi et al. 2023a) suggest the stock is below MNPL. However, more recent analyses suggests that the carrying capacity of the ENP stock has changed. Stewart et al. (2023) estimate K at 22,062. In the absence of direct measurements, a model-derived value of 60 percent can be used to estimate MNPL. Using this approach, the data in Stewart et al. (2023) suggests that MNPL, which is the lower bound of OSP, would be 13,237 animals. This suggests the ENP stock is currently within OSP.

Potential Biological Removal Level (PBR)	0.12 whales/year (Carretta et al. 2023)	409 whales/year (or less) (derived from sources above; see Subsection 3.4.3.3.4, ENP Status, Carrying Capacity, and Related Estimates)	3.1 whales/year (Harris et al. 2022)
IWC Catch Limits (2019-2025)	n/a	Up to 140 whales/year (980 max over 7 years) (IWC 2022a; Fominykh and Wulff 2023)	n/a
Human-caused Mortality and Serious Injury – Minimum Estimates			
Recent Subsistence/Native Harvest	Unknown; not targeted by native hunters	125.6 whales/year by Chukotkan hunters[56] [range 107-137 whales/year from 2017-2021] (IWC Annual Reports)	n/a (Carretta et al. 2023)
Commercial Fisheries	Unknown; 28 of 150 photo-identified whales had entanglement-related scars[57] (Bradford et al. 2009)	9.3 whales/year (Carretta et al. 2023)	1.1 whales/year (Carretta et al. 2023)
Ship Strikes	Unknown; 3 of 150 photo-identified whales had collision-related scars (Bradford et al. 2009)	1.8 whales/year (Carretta et al. 2023)	0.6 whales/year (Carretta et al. 2023)
Total	***Unknown***	***131 whales/year***	***1.7 whales/year***

3.4.3.5 Welfare of Individual Whales

The MMPA and WCA provisions discussed in Subsection 3.4.2, Regulatory Overview, describe considerations relevant to the welfare of individual whales in an aboriginal subsistence hunt. Any permit issued by NMFS under the MMPA must include a finding that the taking is humane, defined as inflicting the least possible degree of pain and suffering practicable (16 USC 1362(4); 50 CFR 216.3). The IWC has focused on reducing the length of time to death of a whale (i.e., reducing the amount of time between the strike and the death of a whale) to improve the humaneness of whaling (IWC 2004c; IWC 2007a; IWC 2012g). The IWC definition of humane killing is "[d]eath brought about without pain, stress, or distress perceptible to the animal. . . . Any humane killing technique aims first to render an animal insensitive to pain as swiftly as technically possible. In practice this cannot be instantaneous in a scientific sense" (IWC Resolution 2004-3). Aboriginal subsistence whalers are urged to do everything possible to reduce any avoidable suffering caused to whales in hunts (IWC Resolution 1997-1), and governments are

[56] All whales killed by Chukotkan hunters are assumed to be from the ENP stock.

[57] Scars are not necessarily indicative of serious injury; non-serious injury may result in scars as well.

encouraged to provide appropriate technical assistance (IWC Resolution 1999-1). The IWC criteria for determining the time to death and insensibility in hunted whales in the field are as follows: 1) relaxed lower jaw, 2) no flipper movement, or 3) sinking without active movement.

Pain has been defined as "an unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage" (International Association for the Study of Pain 1979). Researchers have proposed assessing pain in animals by measuring physiological changes (such as pulse rate, blood pressure, or blood cortisol levels, etc.) and behavioral indicators (such as vocalization, avoidance, shaking, etc.) (Keefe et al. 1991).

Any hunting under the WCA must not be conducted in a wasteful manner. Two issues relevant to humaneness are also relevant to wastefulness: killing only as many whales as are needed for subsistence and subsistence uses (50 CFR 216.3), and ensuring that hunters quickly kill and land struck whales, rather than striking and losing them. The concept of waste includes issues beyond welfare of individual whales, such as ensuring that hunters quickly tow killed whales to shore and butcher them rapidly to avoid spoilage.

3.4.3.5.1 Review of Hunting Methods

The method of the hunt includes total whaling operations and practices, including vessels and weapons. Primary weapons are those used initially to strike and secure the whale. Some primary weapons are also capable of killing the whale. If the primary weapon does not also kill the whale, a secondary weapon is used. The secondary weapon may be the same as the primary weapon, but used additional times. Hunting weapons are also discussed in conjunction with public safety in Subsection 3.15.3.5.2, Weapons Associated with the Hunt. This section discusses weapons in conjunction with the welfare of individual whales.

The Makah Tribe's proposed action includes hunting whales using a traditional wood canoe (with harpooner and crew) accompanied by a motorized chase boat (with a rifleman and an observer), with one of these vessels also carrying the whaling captain. Because the maximum speed of a gray whale may exceed that of a paddled canoe, the Makah whalers must stealthily approach a whale by either approaching a slow moving whale quietly or positioning their canoe in the expected path of a surfacing whale. This FEIS also examines an alternative of an all-motorized hunt, in which the Makah hunters who are striking the whale are also in a motorized vessel instead of a traditional wood canoe. In either event, after a Makah hunter struck a whale with the hand-thrown toggle point harpoon attached to a line and floats, a rifleman in the chase vessel would kill the whale by using a .50 caliber or larger rifle aimed at the central nervous system (Subsection 3.15.3.5.2, Weapons Associated with the Hunt).

This FEIS examines alternative weapons for hunting gray whales by Makah subsistence hunters. These include the use of a hand-thrown darting gun as the primary weapon for striking whales and explosive projectiles delivered by either a second darting gun or a shoulder gun as the secondary weapon for killing whales (and it may be desirable to attach additional floats using a toggle-point harpoon to keep a struck whale from sinking). Both the weapons proposed by the Makah Tribe and the alternative weapons examined are used in other subsistence whale hunts, as well as in commercial hunts.[58] Information from these hunts may be relevant to assessing the impacts of the proposed weapons on the welfare of individual whales compared to alternative weapons.

Alaska Natives hunt bowhead whales in the Bering, Chukchi, and Beaufort Seas using hand-thrown darting guns as their primary weapons to strike whales, securing them with lines and floats. The darting gun delivers an explosive grenade, which may also kill the whale. The secondary weapon in this hunt is also an explosive grenade, delivered either by another hand-thrown darting gun or a shoulder gun. The darting gun can deliver either a black powder or a penthrite projectile, the latter being preferred because black powder can taint the taste of the whale meat (Associated Press 2005). Although the penthrite grenades are expensive and some hunters are reluctant to use them, the chairperson of the Alaska Eskimo Whaling Commission (AEWC) has most recently reported that their use and success is increasing (IWC 2011d; IWC 2012h).

Aboriginal subsistence hunters (Chukotka Natives) in Russia hunt gray whales using hand-thrown toggle-point harpoons to strike whales and either smaller caliber rifles (for whales up to 33 feet [10 m]), hand-thrown darting guns (for whales over 33 feet [10 m]), or both to kill whales (IWC 2007a). (The use of larger caliber weapons by civilian personnel was prohibited in the Russian Federation under national legislation [IWC 1997]). Chukotka Natives have experience with penthrite grenades, but their use is not widespread.

Aboriginal subsistence hunters in West Greenland use deck-mounted harpoon cannons that also deliver penthrite grenades as the weapon for both striking and killing fin whales (Greenland Home Rule Government and Greenland Hunter's Organization 2006; IWC 2007a). They also use this weapon for striking minke whales. If the whale is not killed by the first strike, they use a high caliber rifle as the killing weapon (either a 7.62 mm with full metal jacket bullets, or a .375

[58] A report from an IWC workshop on euthanasia protocols (IWC 2014c) recommended high-caliber ballistics and explosives for baleen whales.

caliber rifle with round-nosed bullets). In east and west Greenland north of Disko Bay, a collective subsistence hunt occurs for minke whales in which the hunters use hand-thrown harpoons (without explosive charges) to strike the whales and a 7.62 mm or .375 caliber rifle as the killing weapon.

Commercial hunters in Norway use deck-mounted harpoon guns that also deliver penthrite grenades as the primary weapon for striking minke whales (Øen 2006; IWC 2007a). If the penthrite grenade does not kill the whales, hunters use rifles as a backup (secondary) killing method, including 9.3 mm, and .375 and .458 caliber rifles with full metal jacket bullets or round-nosed ammunition. The deck-mounted cannons used in the Greenland and Norwegian hunts are not comparable to the two methods examined in this FEIS (the darting gun and shoulder gun). Information about the use of rifles as secondary killing weapons in these hunts, however, may be relevant to analyzing impacts of the Makah Tribe's proposed killing weapon.

3.4.3.5.2 Whale Response to Being Pursued

The Makah Tribe's proposed action includes approaching and pursuing whales using a combination of traditional and modern methods, including the use of canoes accompanied by one or more chase boats with an outboard motor (Subsection 2.3.2, Alternative 2, Tribe's Proposed Action). In addition, this FEIS also examines the alternative of an all-motorized hunt, with no canoe. Based on its experience during the 1999 to 2000 hunts, the Tribe estimates there could be approximately 10 approaches and 4 unsuccessful harpoon attempts for every whale struck. An unsuccessful harpoon attempt means the whale would not be struck (that is, would not have a harpoon embedded and would not show evidence of potentially lethal injury). The Tribe also estimates that the number of whales subject to approaches with no harpoon attempts in any calendar year would not exceed 140.

At the 2003 IWC Workshop on Whale Killing Methods, the United Kingdom presented a paper raising concerns that whales experience stress as a result of being pursued and can exhibit stress-related symptoms such as impaired immune defense, reduced fecundity, failure to grow, and a disease called exertional myopathy (IWC 2004c). This has not been documented in gray whales (but see Lemos et al. (2022), described in Subsection 3.4.3.6.5, Offshore Activities and Underwater Noise), and there are no data at present to evaluate what level of activities may induce this in gray whales. The response of gray whales to pursuit from whale-watching vessels (and vessel presence in general, such as those accompanying any potential whale hunt) is discussed in Subsection 3.4.3.6.6, Vessel Interactions. No data are available specifically regarding the response of gray whales to non-motorized vessels (i.e., human-powered vessels

such as kayaks), but non-motorized vessels generally are addressed, along with motorized vessels, in whale-watching guidelines and regulations globally (Carlson 2004).

During the unauthorized hunt in 2007, the Makah Tribe's biologist reported on the distribution and behavior of gray whales that had been sighted in the vicinity of the whale that had been harpooned, shot, and eventually killed (Scordino 2007b). Anecdotal reports noted that other gray whales could be seen spouting in the area during the hunt and seemed unaffected by the hunt or Coast Guard and fishing boats in the area. Three days after the hunt, the Tribe's biologist sighted two gray whales within 0.6 miles (1 km) of where the killed whale had been harpooned, and noted that these whales exhibited "normal feeding behaviors and showed no escape behavior or agitation when approached by the vessel for photographs."

3.4.3.5.3 Whale Response to Being Struck

It has been reported since at least the 1800s that gray whales (also called 'devil fish') could be dangerous prey when hunted, commonly crashing into whaling boats with their heads (Henderson 1984) (refer to Subsection 3.15.3.3 Behavior of the Gray Whale). The Russian Federation reported that of the 129 whales harvested during the 2007 Chukotkan gray whale hunt, 49 animals (39 percent) "were highly aggressive, and threatened or even attacked hunting boats, so it could definitely be said that every third whale was dangerous for whalers" (IWC 2007b). Subsequent reports from this hunt continue to cite such aggressive behaviors in 32 to 42 percent of gray whales taken (IWC 2009a; 2010b; 2012i).

Under the Makah proposal, the harpooner would strike the whale with a stainless steel toggle-point harpoon with a line and floats attached (for the definition of and evidence for a strike, refer to Subsection 2.3.2.2, Gray Whale Hunt Details). The harpoon point is intended to penetrate the whale's skin (blubber), toggle open, and secure the whale. The harpoon can penetrate and successfully secure the whale in numerous locations on the whale's body, although harpoons may dislodge from whales. Whether the harpoon holds or dislodges depends on, among other factors, the force at impact, the angle of the strike, and the surface characteristics (hard underlying connective tissue, barnacles, etc.). Hunters will often use additional harpoons to attach floats to keep the whale afloat. During the 1999 hunt, Makah whalers struck the whale with three harpoons, the third of which was thrown moments after the rifle shot that rendered the whale motionless (Gosho 1999). Whale responses to being struck with a toggle-point harpoon may include increased swimming speed, diving (Øen 1995), thrashing, and ramming boats (Henderson 1984). A harpoon damages only the organ it hits, and its impact is likely too low to damage the central nervous system (Knudsen and Øen 2003); thus, it may not immediately cause the whale's

death. However, whales may subsequently die as a result of a harpoon strike (Angliss and Lodge 2002).

Whale responses to being struck by a hunting or training harpoon throw could be similar to responses to tagging or biopsy darting for scientific research purposes. Specific gray whale reactions to scientific research tagging include fluke-slapping and rapid swimming, brief startles or flinches, but the whales returned to normal behavior shortly after tagging (Harvey and Mate 1984). The response of gray whales to biopsy darts has not been described, but other mysticetes are observed having brief, sometimes dramatic, changes in behavior, or sometimes no reaction at all (Clapham and Mattila 1993; Gauthier and Sears 1999).

This FEIS examines the use of a hand-thrown darting gun as an alternative method of striking and securing whales, although it is unlikely to be used by the Tribe (Subsection 3.15.3.5.2, Weapons Associated with the Hunt). The darting gun delivers an explosive grenade that detonates inside the whale and kills via shock waves and shrapnel. A grenade delivered by a hand-thrown darting gun may kill the whale, but a secondary method of killing is often required (Øen 1995; O'Hara et al. 1999). Hand-thrown darting guns are aimed at the cervical (neck) and thoracic (chest) region, rather than the head, as the skull is not easily penetrated by the grenade (Butterworth and Brakes 2006; IWC 2007a). Whale responses to being struck with a grenade from a hand-thrown darting gun include death, insensibility, and stunning (Knudsen and Øen 2003), as well as diving (Øen 1995), thrashing, and ramming boats (Bockstoce 1986).

Øen (2006) reported on improvements to hunting and killing methods for minke whales in Norway, in particular, refinements of the penthrite grenade. He noted that the instantaneous death rate in these hunts had increased from 17 percent in 1981 to 1983 to 80 percent in 2000 to 2002 in large part because of improved grenades and hunter training. Data regarding the number of bullets or harpoons used to kill whales do not necessarily indicate the proportion of whales killed by the first strike as hunters are encouraged to re-shoot whales if there is any doubt the whale is still alive (Knudsen 2005; IWC 2007a). In the Alaska Native bowhead whale hunt, Øen (1995) reported that the shoulder gun is used almost routinely after the darting gun has been fired. The Alaska Native data reported to the IWC do not include the number of whales killed by the first strike, possibly because of this routine firing of additional grenades and because of the difficulty in determining whether a struck whale is dead (IWC 2004c). Øen (1995) conducted field studies with penthrite grenades in the Alaska bowhead hunt in 1988 and reported that seven of the eight whales struck with penthrite grenades died from the first grenade thrown; the eighth whale required three grenades. More recently, the United States reported to the IWC that most of the

Alaskan villages now have access to the new penthrite grenades and that these often result in instant kills (IWC 2011d). The Russian data reported to the IWC also do not include the proportion of whales killed by the first strike from a darting gun. The data from the Greenland and Norwegian hunts, which use large vessels and deck-mounted harpoon guns and cannons, cannot be readily compared to the Makah (or Alaska Native) hunts, which use small vessels and light weapons.

3.4.3.5.4 Method of Killing and Time to Death

Rifle as the Killing Weapon

Hunters killing a whale with a rifle aim for the whale's central nervous system (especially the brain), with the intent of causing immediate death or unconsciousness (Knudsen and Øen 2003). The accuracy of the first shot is important for the following reason:

> [H]unting with rifle or shotguns involves an inevitable risk of only wounding the animal, as the projectiles are fired from a distance and the animals often present a moving target. The area of impact of the first round will always be decisive with regard to how quickly the animal collapses and dies (Knudsen 2005).

The Makah propose to use a .50 caliber rifle to kill any whale struck and secured with the toggle-point harpoon. In 1999, shots from a larger .577 caliber rifle used by the Tribe produced a time to death of 8 minutes from the time the harpoon struck the whale until the final rifle shot rendered the whale motionless (Gosho 1999) [59]. Gosho (1999) reported that the killed gray whale was a female approximately 30.5 feet (9.3 m) in length. The necropsy performed after the hunt indicated that the first shot that entered the whale hit the skull and stunned it, while the second shot that entered the whale penetrated its brain and likely killed it instantly (Gosho 1999; IWC 2004c). During the unauthorized hunt in 2007, at least 16 shots struck that whale and it took approximately 9 hours to die (Scordino 2007a,b). It is not known what caliber rifle was used to shoot the whale, which was estimated to be about 40 feet (12.2 m) long (Mapes 2007), but the Makah marine biologist reported that the hunters were in possession of both a .460 and a .577 rifle. He also noted that the whale would have died much sooner if—in addition to other factors[60]—the primary rifle (.577) had not been lost overboard (Scordino 2007a,b).

[59] A total of four rifle shots were fired over the span of five minutes; the first two shots either missed or were ineffective but the final two shots hit near the blowhole.

[60] Other reasons contributing to the whale's prolonged death likely included insufficient ammunition; inadequate hunter training; poor shot placement; slow communication time between U.S. and tribal officials; and the Coast Guard's rapid response time and curtailment of the unauthorized hunt (Scordino 2007a, 2007b).

Three separate reports (Ingling 1999; Beattie 2001; Graves et al. 2004) examined past Makah proposals and concluded that a .50 caliber rifle (or greater) is the appropriate caliber of rifle to use, after testing it alongside smaller caliber weapons. Ingling (1999) concluded that for large game, larger bullets are more effective in producing penetration deep enough to reach a vital organ or disabling site in the animal and thus require more power (i.e., heavier guns). In addition, rifles that are at least .50 caliber provide a better margin of error in targeting compared to smaller caliber rifles. Graves et al. (2004) concluded that the .50 caliber rifle was the best weapon choice and added that "small caliber rifles simply will not do the job" of quickly dispatching whales with large size and thick bones.

Graves et al. (2004) recommended that Makah hunters use a .50 caliber cartridge with an Arizona Ammunition Match grade 750-grain bullet, noting that it is one of the most common cartridges used in .50 caliber competitions and by specialized units of the U.S. Government. They computed that the maximum range[61] for this cartridge is 4.97 miles (8 km), a distance similar to that reported in the U.S. Army field manual for the .50 BMG (4.23 miles/7.44 km) and other reports citing maximum ranges from 4.04 to 5.0 miles (6.50 to 7.40 km) (U.S. House of Representatives 1999; Kline 2001; Barrett Firearms 2011; McRae, C.K., U.S. Army, pers. Comm. April 10, 2013). For comparison, the .577's lower ballistic coefficient (i.e., relative ability to overcome air resistance) and greater rate of drop would be expected to result in a shorter range than that calculated for the .50 caliber cartridge recommended by Graves et al. (2004).

Although the .577 caliber rifle used in the 1999 hunt was effective at quickly killing an adult gray whale, Graves et al. (2004) and Graves and Hazelton (2004) rejected this rifle because of the difficulty of obtaining ammunition. It is unclear if the .577 rifle lost during the illegal hunt in 2007 can be replaced, as well as whether suitable ammunition will be produced in the future (i.e., the manufacturer went out of business, and the business was acquired by new owners who no longer produce bolt-action rifles) (Graves and Hazelton 2004; Broadsword Group 2013). Therefore, it is most likely that the Makah hunters will use the recommended .50 caliber weapon, but it is possible that a larger caliber weapon will be used.

[61] The maximum range is the greatest possible distance that a bullet can reach, assuming the rifle is held at an optimum elevation angle and accounting for environmental variables (e.g., sea-level conditions, temperature, etc.). However, the Makah's proposal cites public safety measures that would authorize the discharge of firearms when whaling only when the shooter 1) was within 30 feet (9.1 m) of the target area of a whale; 2) had a field of view that was clear of all persons, vessels, and other objects that could result in injury or loss of human life; and 3) had a minimum visibility of 500 yards (457.2 m) in any direction.

Dr. Allan Ingling noted that the whale hunting rifles are probably the single most important items on which the success or failure of the hunt depends and underscored that rifles must be tested for their effectiveness before they are used in a hunt (A. Ingling, Doctor of Veterinary Medicine, pers. comm., August 2, 2010). He observed that the .577 had a clearly demonstrated ability to humanely dispatch a gray whale but also identified a range of possible calibers from .458 to .700.[62] Dr. Ingling also expressed reservations about a .50 caliber that was heavy (some models weigh 30 lbs (14 kg) or more), had a single-shot capacity, and a muzzle break[63] creating dangerous blast and noise issues in the restricted space of a boat. In his 1999 report, Ingling noted that "the weight of the [tested] .50 BMG, 20 lbs. (9 kg) versus the weight of the .577, 14 lbs. (6.4 kg), and more importantly, the 3-shot magazine of the .577 clearly makes the .577 the more suitable weapon for humanely dispatching gray whales." Gun manufacturers continue to modify the .50 caliber. There are currently models available that are as light or lighter than the .50 caliber rifle tested by Ingling (1999), have multi-round magazines, and modern muzzle break or silencer systems that may reduce blast and noise concerns (e.g., Anzio Ironworks 2013; MICOR 2013). Therefore, we consider the Tribe's proposed .50 caliber rifle, with its readily available supply of ammunition, the weapon that Makah hunters would most likely use.

This FEIS does not examine the use of a different, smaller caliber rifle as the killing weapon (Subsection 2.4.6.2, Kill Whales with Smaller Caliber Rifles, explains why this alternative was considered but eliminated from detailed study). In the Russian Federation, the Chukotka Natives hunt gray whales using smaller caliber rifles as well as hand-thrown darting guns. The Russian Federation reported that during the 2002 harvest, approximately 28 percent of whales struck were killed with various rifles ranging in size from .22 to .32 caliber. Hunters used from 3 to 100 bullets per whale in 2002 and an average of 54 bullets per gray whale killed (down from 64 bullets per whale in 2000; IWC 2004c). Mean time to death for both the rifle and darting gun was 32 minutes for gray whales, with a maximum time to death of 56 minutes (IWC 2004c). For the 2008 hunt, the Russian Federation reported that the maximum number of shots per gray whale killed was 140 and the mean and maximum time to death was 31 minutes and 95 minutes, respectively (IWC 2009b). During the 2011 hunt, Chukotkan hunters again used darting guns and rifles, averaging 92 bullets per gray whale killed (with a reported maximum of 250 bullets) and a

[62] "The only other record of a .577 being used to kill a whale was in April 2010, when a team of biologists and veterinarians (including Dr. Ingling) used three shots from a .577 in combination with drug injections to euthanize a 30-foot (9.1 m) long humpback whale that had stranded in heavy surf in East Hampton, New York" (NMFS 2010).

[63] A device fitted to the end of the barrel that reduces gun recoil by re-directing gases that propel the bullet.

mean time to death of 37 minutes and a maximum time to death of 125 minutes (IWC 2012j). During the 2016 hunt, Chukotkan hunters used the same hunting methods (darting gun and .30 caliber rifle), averaging 68 shots per gray whale killed (with a reported maximum of 252 shots) and a mean time to death of 24 minutes (reported maximum of 135 minutes) (IWC 2018e). During the 2017 hunt and using the same hunting methods as in 2016, Chukotkan hunters averaged 80 shots per gray whale killed (with a reported maximum of 280 shots) and a mean time to death of 29 minutes (reported maximum of 185 minutes (IWC 2018e). The average time to death has decreased since 2001, when the average was 55 minutes (IWC 2018f).

Minke whales are also hunted with rifles; however, these whales are substantially smaller than adult gray whales. In the Greenland collective minke whale hunt, the animals are usually first wounded with shots from a rifle (typically .30 caliber), then secured with hand-thrown harpoons before finally being killed with rifles (Greenland Home Rule Government and Greenland Hunter's Organization 2006).[64] The rifle used in 2005 was identified as a .30 caliber; the number of bullets used was not reported. The average time to death reported for 44 whales killed in the 2005 hunt was 21 minutes, with a maximum time to death of 90 minutes. This report noted that time to death might be shortened if a larger caliber rifle were used, but this could also increase the number of struck and lost animals that die and sink before they can be secured with harpoon lines and floats. In the 2010 and 2011 collective hunts, a rifle of unknown caliber (but larger than .30) was used as the primary weapon in east Greenland minke hunts. Nine whales were killed in 2010, and six of these were assessed for time to death (IWC 2011e). The average time to death was the same as in 2005 (21 minutes) while the maximum time was shorter at 30 minutes. In 2011, 9 out of 10 whales were assessed, with an average time to death of 29 minutes and a maximum time of 90 minutes (IWC 2012m).

In the Norwegian commercial hunt for minke whales, Knudsen and Øen (2003) concluded that the .357 and .458 caliber rifles and ammunition used "are highly capable of causing permanent brain damage of sufficient severity to account for an instantaneous or rapid loss of consciousness." According to Knudsen (2005), "[a] whale that is shot in or near the brain with the rifle will also normally turn over immediately and the flippers and jaw will relax." In the Norwegian hunt, almost all whales (95.5 percent) are killed with the first strike by a penthrite grenade (Øen 2006), and the time to death is not separately reported for whales killed with

[64] When possible, the harpoon is used to secure the whale before wounding it.

bullets. For whales killed with a rifle after the grenade failed to kill the whale, the mean number of bullets used was 2.6 (in the 1998/1999 season), 2.2 (in the 2000/2001 season), and 2.2 (in the 2001/2002 season) (Knudsen 2005).

Explosive Grenade as the Killing Weapon

In addition to the Makah Tribe's proposal to kill whales using a .50 caliber rifle, this FEIS examines use of an explosive projectile to kill the whale, delivered by either a hand-thrown darting gun or a shoulder gun (Subsection 2.3.2.2, Gray Whale Hunt Details), though it is uncertain whether grenades would be readily available for a Makah Tribe gray whale hunt (Subsection 3.15.3.5.2, Weapons Associated with the Hunt). The cervical and cranial thoracic regions of a whale are the critical target areas for explosive projectiles. Penetration into these regions results in detonation next to the skull and vertebrae, or within the thoracic cavity (O'Hara et al. 1999). How effective the grenade is in killing the whale quickly will depend on where the whale is hit and whether the projectile penetrates to a suitable depth (O'Hara et al. 1999).

Two types of grenades are currently available and in use (e.g., by Alaska Native hunters)—slow-burning black powder grenades and fast-burning penthrite grenades. Both types have a time-delay fuse designed to detonate the grenade after penetrating the whale. Detonation releases fragments, or shrapnel, causing hemorrhaging and damage to internal organs (O'Hara et al. 1999). The blast from a black powder grenade also emits shock waves that can cause concussion-related injuries to the brain or internal organs (O'Hara et al. 1999). The blast from a penthrite grenade emits a much higher energy shock wave, which is more likely to cause concussion-related injuries further from the blast site, including injuries to the whale's brain or internal organs. These injuries may cause insensibility or immediate death (Øen 1995; O'Hara et al. 1999). If the grenade does not hit a target area, it has a higher probability of killing the whale than a black powder grenade because it can cause damage farther from the point of detonation (O'Hara et al. 1999; Smith 2007).

In 1988 through 1992, Øen (1995) conducted field trials using penthrite projectiles in the Alaska Native bowhead hunts and comparing them to black powder projectiles used from 1984 to 1986. Data for black powder grenades were the most reliable for 1988 because the information was systematically collected. Results showed reduced time to death for penthrite as compared to black powder (Øen 1995). In 1988, five of the eight bowhead whales (63 percent) died in less than 5 minutes (Øen 1995). The grenades were modified subsequent to the initial penthrite field trials, and data in 1997 and 1998 indicated that time to death was 50 percent of the time to death for black powder grenades (O'Hara et al. 1999). At the 2006 Whale Killing Method Workshop, the AEWC reported that, when placed near the blow hole or within the thorax, the penthrite

projectiles appear to give a more rapid time to death than traditional black powder (Alaska Eskimo Whaling Commission 2006; IWC 2007a). The chairperson of the AEWC weapons improvement program has also reported a general preference among Alaska Natives for penthrite, rather than black powder grenades, because "with black powder, the meat has a gas taste" (Associated Press 2005). In 2011, the chairperson of the AEWC reported that penthrite grenades had been distributed to over half of the villages and that the use of these weapons "can reduce the time to death for a bowhead whale to 4 seconds, this being the length of time on the grenade's fuse" (IWC 2011d). The following year the chairperson reported that the use and success of the new penthrite grenade was increasing (IWC 2012h).

The Chukotka Natives use both rifles and darting guns to kill whales. They have used penthrite grenades, but they primarily use black powder grenades. At the IWC Annual Meeting in 2003, the Russian Federation reported that approximately 72 percent of whales killed were killed using the darting gun. Mean time to death for gray whales using both methods was 43 minutes, with a maximum of 220 minutes. In the 2002 season, hunters used an average of 2.7 darting gun projectiles per whale killed (IWC 2004c) and this ratio has remained relatively stable during the past decade (Borodin et al. 2012). The mean and maximum time to death for gray whales killed with darting guns in the 2002 hunts was 32 minutes and 56 minutes, respectively. In 2006, for whales killed using a darting gun with a black powder explosive projectile, Chukotka Native hunters reported an average time to death of 32 minutes for 88 whales (minimum 3 minutes, maximum 3 hours) (IWC 2007c). In 2011, the government of Chukotka purchased 45 darting guns to improve the humaneness of the gray whale hunt (IWC 2012g). In the 2016 hunt, Chukotka Natives used darting guns on 40 of the 120 total whales killed in the 2016 hunt, and 40 of the 119 total whales killed in the 2017 hunt (IWC 2018e).

3.4.3.5.5 Proportion of Whales Struck and Lost

During the Makah Tribe's 1999 and 2000 hunts, there were no whales struck and lost; the only whale struck was landed (Gosho 1999; Gearin and Gosho 2000). In the 2007 unauthorized hunt involving several Makah Tribal members, the whale was struck and then allowed to die and sink several hours after enforcement agents stopped the hunt (Scordino 2007a, 2007b).

As noted previously, the Chukotkan hunt for gray whales is not directly comparable to the Makah Tribe's proposed hunt because the Chukotkans use harpoons and either smaller caliber rifles, darting guns, or both (IWC 2007a; IWC 2018d). Of the more than 1,400 whales struck by Chukotkan hunters during the period 2003 to 2013, only 2.3 percent have been struck and lost (IWC Annual Reports 2004-2014; Ilyashenko 2013; Ilyashenko and Zharikov 2013). In more

recent years, from 2014-2021, an average of 1 percent have been struck and lost. The ratio of struck-and-lost whales to total whales struck is shown in Table 3-12.

Table 3-12. Number of struck-and-lost whales to total whales struck in Chukotkan gray whale hunts.

Year	Struck and Lost	Total Struck

Source: IWC Annual Reports 2004-2012, Ilyashenko 2013, and Ilyashenko and Zharikov 2013; IWC Scientific Committee Reports 2015-2022

Most of the bowhead whales in the Alaska Native hunt are hunted using hand-thrown darting guns and shoulder guns with black powder grenades. During a field trial of penthrite grenades in 1988, Øen (1995) reported that seven of the eight bowhead whales (88 percent) struck with the penthrite projectile were landed. In 1978, the AEWC committed to the IWC to increase the

efficiency (i.e., proportion of whales struck vs. landed) of their bowhead hunt from an average of 50 percent to an average of 75 percent. In 2011, the AEWC reported that while there can be significant year-to-year variability, the 13-year average efficiency was 77.3 percent from 1996 to 2010. In the 2010 hunt, eight whales were struck with the penthrite projectile and five were landed after instant or near-instant kills (IWC 2011d). A report from the AEWC (IWC 2012h) states that during the 2011 bowhead hunt 51 whales were struck and 38 whales were landed (a 74.5 percent efficiency). It also notes that a total of 26 whales were reported as instant or near-instant kills, including all but three of those taken using penthrite grenades. Also, results from the 2012 spring hunt indicate that hunters from one village took six whales using penthrite grenades; all were reported as very quick kills and no whales were lost (IWC 2012h). In the most recent report available (IWC 2022b), 70 bowhead whales were struck in the 2021 Alaska Native subsistence hunt, of which 57 were landed, yielding a slightly higher harvest efficiency (81 percent) than the average over the last 10 years (78 percent from 2011-2020).

3.4.3.5.6 Training and Weapons Improvement

The Makah's proposed action includes a training and certification program. The Tribe also proposes to conduct research and development to refine hunting methods further and revise tribal regulations periodically to improve the safety, effectiveness, and humaneness of the gray whale hunt. This provision is similar to the Alaska Eskimo Whaling Commission's Weapons Improvement Program, which has worked since the late 1980s to develop newer technologies (including use of the penthrite grenade) to increase hunting safety and efficiency (IWC 2011d). Hunter training would likely reduce time to death and decrease the proportion of struck and lost whales (Alaska Eskimo Whaling Commission 2006; Greenland Home Rule Government and Greenland Hunter's Organization 2006). Dr. Ingling emphasized the need for a codified training and qualification program, including regular re-certification for the various whaling crew duties and training in gray whale anatomy (A. Ingling, Doctor of Veterinary Medicine, pers. comm., August 2, 2010).

3.4.3.5.7 Weather and Sea Conditions

Weather and sea conditions in the action area as they relate to safety are discussed in detail in Public Safety, Subsection 3.15.3.2, Weather and Sea Conditions. Weather and sea conditions, including motion of the vessel, also may have implications for harpooner or rifleman accuracy, which could affect a whale's time to death and the proportion of whales struck and lost. The efficiency of the hunt could also be affected by these conditions if they improve the ability of the Tribe to successfully tow and land a killed whale. The Makah proposal includes the use of a

motor-powered vessel to position the rifleman and to tow a killed whale to shore, and it includes maintaining a 30-foot (9.1-m) maximum distance from the rifleman to the whale with minimum visibility of 500 yards (457.2 m).

3.4.3.5.8 Behavior of People Associated with the Hunt

The behavior of people associated with the Makah hunt, including protesters, is also discussed in detail in Public Safety, Subsection 3.15.3.4, Behavior of People Associated with the Hunt. Based on the 1999 and 2000 protester interventions on the water, and the continuing degree of public and media interest in this issue, vessels and people may interfere with whaling activities, increase the time to death, and increase the potential for not successfully landing a whale struck by Makah hunters.

3.4.3.6 Known and Potential Anthropogenic Impacts

Particularly along the coast of North America, gray whales are exposed to intense human activity. Moore and Clarke (2002) concluded that "[t]he recovery of the gray whale population in the face of long-term exposure to human activities along the North American coast suggests a strong degree of tolerance to such activities." The recovery of the ENP gray whale stock in the face of aboriginal subsistence hunting by Chukotka Natives similarly suggests a tolerance to such activity. The following discussion examines some of the more prominent activities affecting gray whales.

3.4.3.6.1 Aboriginal Subsistence Whaling

ENP gray whales have been hunted by various aboriginal groups for hundreds to thousands of years. In the whales' northern feeding areas, five groups of aborigines hunted along the Chukotkan Peninsula of northeastern Asia in the western Bering, northeastern Okhotsk, and western Chukchi Seas, including the Asiatic (Siberian) Eskimos, Chukchi, Koryaks, Kereks, and Itle'mens (Kamchadals) (Krupnik 1984). The (Alaska) Natives also hunted gray whales along the northwestern shores of North America in the eastern Bering and Chukchi Seas for thousands of years (O'Leary 1984). Along the whales' migratory corridors and in the more southern feeding areas south of the Alaskan Peninsula, several Indian tribes between the Aleutian Islands and California hunted gray whales and/or used drift whales for subsistence as a part of their cultural and religious traditions, including the Aleuts, Koniag, Chugash, Tlingit, Haida, Tsimshian, Nootka, Makah (including Ozette), Quileute, Klallam, and Chumash (O'Leary 1984). Some of these tribes hunted during the American and industrial commercial whaling eras. The last Makah hunts in this timeframe were recorded in the 1920s. Table 3-13 identifies the historical (1600 to

1943) aboriginal catches of ENP gray whales reported by Punt and Wade (2012), amounting to nearly than 55,000 whales (approximately 160 whales per year) during that 343-year period.

Table 3-13. Estimated historical (pre-1944) aboriginal catches of ENP gray whales.

Years	Annual # Killed	Years	Annual # Killed
1600-1675	182	1881-1890	108
1676-1750	183	1891-1900	62
1751-1840	197.5	1901-1904	61

1876-1880	110	1940-1943	20

Source: Punt and Wade 2012.

Between 1948 and 1955, subsistence hunters in the Chukotkan Region took 241 total gray whales, averaging 30 whales annually (Zimushko and Ivanshin 1980). From 1956 to 1968, the catches in that region increased to an average 158 animals annually (Zimushko and Ivanshin 1980). From 1968 to 1977, the Soviet Ministry of Fisheries imposed catch limits of 140 to 150 whales from 1968 to 1972 and 200 whales annually from 1972 to 1977 (Zimushko and Ivanshin 1980). The IWC established aboriginal subsistence whaling catch limits for the ENP gray whale stock starting in 1978 (Table 3-14). Since then, 5,605 harvested gray whales have been reported to the IWC (averaging just over 127 whales per year), with all but 26 of these whales being taken by Russian/Chukotkan hunters. These hunters typically hunt gray whales beginning in June or July, when the waters become ice free (Krupnik 1987), and continue through the summer and fall. For example, all of the gray whales harvested by Chukotkans in 2009 were taken between June and November, while in 2011 the first and last whales were harvested on May 15 and November 8, respectively (IWC 2012k). This trend holds true for more recent years as well: in 2016, the first and last whales were harvested on May 7 and November 22, respectively, and in 2017, the first and last whales were harvested on May 11 and October 24, respectively (IWC 2018e). Gray whale catches that the United States reported to the IWC include the one whale harvested by the Makah Tribe in 1999 and the one whale killed in 2007 in the unauthorized hunt by members of the Makah Tribe (IWC 2008). More recently, the United States reported to the IWC that Alaska Natives took one gray whale in 2017 and one in 2018 in unauthorized hunts. In the 2018 investigation, the AEWC

noted that the Bering Strait communities were struggling with food due to changing environmental conditions (IWC 2018e). Although Alaska Natives hunted gray whales prior to 1989, the United States has not presented a proposal to the IWC for this hunt, nor has NMFS published a quota under the WCA.

3.4.3.6.2 Environmental Contaminants

Environmental contaminants that enter the marine environment through atmospheric, ocean current, and terrestrial transport originate from a variety of urban and rural anthropogenic sources, including agricultural use of pesticides, industrial disposal of manufacturing or pharmaceutical by-products, industrial processing or burning of fossil fuels, and municipal discharge or runoff associated with landfills, wastewater treatment plants, and miles of streets and roads. Marine ecosystems in the northeastern Pacific receive pollutants from a variety of local, regional, and international sources (Grant and Ross 2002; EVS Environmental Consultants 2003; Garrett 2004; Krepakevich and Pospelova 2010).

These chemicals and compounds include organochlorines (e.g., DDT, PCB, dioxins, and furans), heavy metals (e.g., copper, mercury, and lead), and others such as flame retardants (PBDEs) and PFAS, that may have direct lethal effects on individual animals or insidious effects on animal populations through impaired reproductive, metabolic, and immune functions (O'Hara and O'Shea 2005). Many organochlorines are highly fat soluble and have poor water solubility, which allows them to accumulate in the fatty tissues of animals where most storage occurs (O'Shea 1999; Reijnders and Aguilar 2002). Some are highly persistent in the environment and resistant to metabolic degradation. Bioaccumulation through trophic transfer in the marine food chain allows relatively high concentrations of these compounds to build up in top-level marine predators, such as marine mammals (O'Shea 1999). However, reported levels of contaminants and heavy metals in gray whales are lower than in odontocetes, likely due to their feeding on benthic invertebrates at lower tropic levels (Stimmelmayr and Gulland 2020). Gray whales may ingest these environmental contaminants when they bottom feed in areas where both the sediment and benthic prey are contaminated. A recent study quantified blubber concentrations of persistent organic pollutants (POPs) such as PCBs and DDTs in gray whales and found that concentrations have generally decreased since earlier studies (Hayes et al. 2022). The authors also document PBDEs and other pollutants in the gray whale for the first time. However, the exact health effects of various contaminant levels on gray whales is unknown (Stimmelmayr and Gulland 2020). By comparison, pinnipeds and porpoises carry far greater amounts of PCBs and DDTs than baleen

whales and fish, however, because of their higher positions in food chains (O'Shea and Aguilar 2001; Reijnders and Aguilar 2002).

Subsection 3.16.3.2, Environmental Contaminants in Gray Whales, discusses the 'stinky whale' phenomenon and recent evidence suggesting that naturally occurring bromophenols are responsible for the phenomenon, as opposed to organochlorines as was previously thought (Polyakova et al. 2023).

Subsection 3.16.3.2, Environmental Contaminants in Gray Whales, also addresses concentrations of heavy metals (including mercury, lead, and copper, among others) in gray whale tissues with information synthesized from various studies. The three elements usually considered of greatest concern to cetaceans are mercury, cadmium, and lead (O'Shea 1999). Mercury, cadmium, and other metals accumulate primarily in the liver and kidneys, whereas lead concentrates mostly in bones (Reijnders and Aguilar 2002). Concentrations of most metals tend to increase throughout an animal's life and are stored in fatty tissues. There are, however, organic forms of metals, such as methylmercury, that accumulate in the lipids of prey species. Many marine mammal species can tolerate high amounts of metals or detoxify them (Reijnders and Aguilar 2002; Wise et al. 2009). Published accounts of metal-caused pathology are scarce (O'Shea 1999).

In the 1999 and 2000 mass stranding events, chemical contaminants were a possible factor contributing to the increased mortality (Gulland et al. 2005). Overall, however, no contaminant found would be the direct cause for acute mortality of the observed magnitude (Gulland et al. 2005). The mean concentrations of organochlorines in the blubber of gray whales stranded in 1999 were well below levels observed in apparently healthy gray whales harvested in Russia (Tilbury et al. 2002). Also, lower levels of total mercury and methylmercury were reported in the muscle, kidney, and liver tissues of four gray whales that stranded in the Gulf of California in 1999 than were reported for other marine mammals, though sampling differences and the effect of decomposition on blubber lipids may alter the results of chemical analysis (Gulland et al. 2005).

As described below in Subsection 3.4.3.6.12, Marine Debris, a devastating earthquake and tsunami struck Japan in 2011 and washed an estimated 5 million tons of debris into the North Pacific Ocean. In addition, the tsunami damaged several nuclear reactors in the Fukushima Daiichi Nuclear Power Plant complex causing them to release radiation into the atmosphere and North Pacific Ocean. In response a number of agencies have been actively monitoring water, debris, biota and sediment, with the U.S the Environmental Protection Agency playing a lead role in such U.S. monitoring (EPA 2011a). Radiation experts have determined that it is highly

unlikely that any tsunami-generated marine debris holds harmful levels of radiation. Some marine debris collected along shorelines in Hawaii and on the West Coast, including debris known to be from the tsunami, has been tested, and all readings were normal (Ecology 2013b; EPA 2011a; NOAA 2013).

In response to the Japanese nuclear incident, the EPA accelerated and increased sampling frequency and analysis to confirm that there were no harmful levels of radiation reaching the United States from Japan and to inform the public about any level of radiation detected. After a thorough data review showing declining radiation levels, on May 3, 2011, EPA returned to the agency's routine sampling and analysis process for precipitation, drinking water and milk (EPA 2011a). According to researchers at the Woods Hole Oceanographic Institute, "[l]evels of any Fukushima contaminants in the ocean will be many thousands of times lower after they mix across the Pacific and arrive on the West Coast of North America in 2014. This is not to say that we should not be concerned about additional sources of radioactivity in the ocean above the natural sources, but at the levels expected even short distances from Japan, the Pacific will be safe for boating, swimming, etc." (Woods Hole Oceanographic Institution 2014).

3.4.3.6.3 Harmful Algal Blooms

Single-celled algae are the base of the food chain in the marine environment, and they proliferate or aggregate to form dense concentrations of cells called blooms when certain environmental conditions prevail. Algal blooms can produce marine biotoxins, which can accumulate in fish, seabirds, and other marine biota. Harmful algal blooms occur in coastal marine environments throughout the United States, including waters of Puget Sound and off the coasts of Washington, Oregon, California, and Alaska (Lefebvre et al. 2016). There is evidence that harmful algal blooms have increased in frequency, magnitude, and seasonal duration, possibly as a result of global climate change, toxic algal species extending to new areas, and human-related eutrophication of the coastal environment (Trainer 2002). Though less than 5 percent of the known dinoflagellate species and fewer than 25 species in one genus of diatoms produce compounds that are known to be toxic to marine mammals (Van Dolah 2005), some marine mammal morbidity and mortality, including mass strandings, have been associated with marine biotoxin exposure and harmful algal blooms. Along the west coast of the United States, some of the most deleterious biotoxins produced by harmful algal blooms include saxitoxin (the toxin that causes paralytic shellfish poisoning in humans), domoic acid, and the marine alga *Heterosigma akashiwo* (Horner et al. 1997). Gray whales have thus far been shown to be affected by saxitoxin or domoic acid, as explained below.

Saxitoxin

In 1987, acute levels of saxitoxin, produced by a dinoflagellate bloom, were associated with the death of 14 humpback whales off the coast of Cape Cod, Massachusetts (Geraci 1989; Van Dolah 2005). Saxitoxin was also a contributing factor in the mortality of bottlenose dolphins in a Florida lagoon in 2001 and 2002 (Van Dolah 2005). Scientists have also postulated that chronic, sublethal exposure to saxitoxin through ingestion of copepods may affect right whale reproductive rates by lowering diving rates and feeding time, and decreasing overall fitness (Van Dolah 2005). Researchers have demonstrated that saxitoxin has a high affinity and specific binding to the nerve preparations of the brains of gray whales, humpback whales, California sea lions, and manatees (Trainer and Baden 1999). A small sample of gray whales sampled for contaminants from the ongoing UME had trace levels of saxitoxin (Raverty et al. 2020).

Domoic Acid

In 1991, the first evidence of domoic acid on the west coast of North America was a mass mortality of pelicans and cormorants in Monterey Bay, California (Van Dolah 2005). The first confirmed domoic acid poisoning of marine mammals occurred in 1998 in the same area, when more than 70 California sea lions stranded from San Luis Obispo to Santa Cruz (Scholin et al. 2000). Of the 70 sea lions that stranded, 57 sea lions died because of acute toxicity from eating anchovies (Van Dolah 2005). A similar event occurred in 2000 in the same region, when the stranding of 187 sea lions was associated with domoic acid (Gulland et al. 2002; Van Dolah 2005). Concurrent with the 2000 sea lion mortality event, abnormally high numbers of gray whale strandings occurred (Van Dolah 2005). One of the three gray whales whose cause of death was determined in the 1999 and 2000 unusual mortality event was likely intoxicated with domoic acid (Gulland et al. 2005). The levels of domoic acid in the necropsied whale would indicate acute toxicosis in a laboratory primate, but toxic doses for cetacea are undetermined (Truelove and Iverson 1994). Biotoxins were thus one of the factors listed as potentially contributing to the increased number of gray whale mortalities observed in 1999 and 2000, though too few carcasses were adequately sampled to assess their importance in the mortality event (Gulland et al. 2005). In February 2002, researchers documented a domoic acid event on the California coast. This event involved nine marine mammal species and the deaths of thousands of sea lions; none of the reported strandings or deaths was a gray whale (Van Dolah 2005). In a review of the effects of domoic acid on wildlife, Bejarano et al. (2008) did not report any evidence of toxicity in gray whales. In marine mammals other than California sea lions, the association between exposure to domoic acid and abnormal clinical signs has been limited to epidemiological associations rather than direct measurement of domoic acid in body fluids of affected animals (Lefebvre et al. 2010).

A small sample of gray whales sampled for contaminants from the ongoing UME had trace levels of domoic acid (Raverty et al. 2020).

3.4.3.6.4 Oil Spills and Discharges

Exposure to petroleum hydrocarbons released into the marine environment through oil spills and other discharge sources represents another potential anthropogenic impact on gray whales in the action area. Inhalation of vapors at the water's surface and ingestion of hydrocarbons during feeding are the most likely pathways of exposure. Acute exposure to petroleum products can cause changes in behavior and reduced activity, inflammation of the mucous membranes, lung congestion, pneumonia, liver disorders, and neurological damage (Geraci and St. Aubin 1990). Marine mammals can generally metabolize and excrete limited amounts of hydrocarbons, but acute or chronic exposure poses greater toxicological risks (Grant and Ross 2002).

At the water's surface, gray whales have been observed lying in or swimming through oil from the *Exxon Valdez* oil spill along the Alaska coast (Moore and Clarke 2002), and they have been observed migrating through natural seeps near Santa Barbara, California (Kent et al. 1983). Kent et al. (1983) observed that gray whales generally swam faster, stayed submerged longer, and took fewer breaths than whales that did not pass through oil; whales also sometimes changed direction to swim around the surface oil, though it was not clear that the change in direction was in response to the oil. Some scientists have concluded that cetaceans have a thickened epidermis that greatly reduces the likelihood of petroleum toxicity from skin contact with oiled waters (Geraci 1990; O'Shea and Aguilar 2001). Geraci (1990) proposed that gray whales probably experience eye and tactile hair follicle irritation upon contact with oil but that long-lasting effects to skin tissue were less likely. This observation was based on laboratory tests on bottlenose dolphins, because the dolphins did not exhibit a vascular reaction to contact with petroleum products (Geraci 1990). Other scientists have proposed that cetaceans with rough or damaged skin, such as the barnacle-covered skin of a gray whale, may be more susceptible to oil contamination and subsequent bacterial infection than smoother-skinned cetaceans (Albert 1981). Moore and Clarke (2002) reported that it is unclear whether gray whales can detect surface oil.

Gray whales could consume oil from fouled baleen, by engulfing tar balls, or by bottom feeding on contaminated sediments (Geraci 1990; Moore and Clarke 2002), though there are no reported cases of ingestion. Twenty-five whales that stranded after the *Exxon Valdez* spill had oil on their baleen but not in their digestive tracts, suggesting that the baleen was fouled after death (Moore and Clarke 2002). Geraci and St. Aubin (1985) concluded that oil impact on baleen was slight and short term, based on laboratory tests where 70 percent of oil was flushed from baleen in 30

minutes, but Geraci (1990) proposed that baleen fibers could remain oiled if a whale was feeding in a highly oiled area where fouling outpaced the flushing rate. Moore and Clarke (2002) noted that oil and chemical dispersants, used to break up surface oil and cause it to sink, could contaminate benthic sediments. They proposed that any large-scale contamination of a primary feeding area could negatively affect the population. Inhalation and dermal contact are also exposure pathways that could negatively impact gray whales (Takeshita et al. 2017; Stimmelmayr and Gulland 2020).

Exploration and development of offshore oilfields have the potential to release petroleum products and other contaminants into waters used by gray whales. In 1969, a federal platform offshore of Santa Barbara, California, experienced a blowout in one of its wells, releasing an estimated 3.4 million gallons of oil into the ocean. Since then, until 2015, a total of approximately 37,000 gallons of oil were spilled as a result of natural gas and oil operations offshore of California (Bureau of Ocean Energy Management 2015). In 2015, a crude oil pipeline near Refugio State Beach[65] ruptured and spilled over 100,000 gallons of crude oil that eventually made its way in to the ocean and led to the closure of beaches, fisheries, and recreational areas. In 2021, a pipeline off the Orange County coast spilled 25,000 gallons of crude oil in to the ocean 4.5 miles from shore, which eventually washed up on the beach, leading to closures.[66]

Areas of active oil and gas development within the migratory range of ENP gray whales include Southern California and the Chukchi and Beaufort Seas north of Alaska. Onshore refineries and shipping facilities associated with these areas also present a risk of spills, as does shipping traffic. No oil and gas development occurs in the Pacific coastal waters of Mexico, but a refinery at the coastal city of Salina Cruz processes and ships petroleum products from the Gulf of Mexico. There are no active oil or gas leases off the coasts of Oregon or Washington. A moratorium on leasing for offshore oil and gas exploration and development is currently in place in these areas. An informal moratorium on oil and gas drilling off the coast of British Columbia has been in place since the early 1970s.

During the period from 2000 to 2008, a total of 500,600 gallons of oil was spilled in the Pacific Ocean (U.S. Coast Guard 2010). During the same period, the U.S. Coast Guard (2010) reported

[65] https://darrp.noaa.gov/oil-spills/refugio-beach-oil-spill

[66] https://darrp.noaa.gov/oil-spills/pipeline-p00547-huntington-beach-oil-spill#:~:text=What%20Happened%3F,offshore%20of%20Huntington%20Beach%2C%20California.

approximately 468,000 gallons of oil spilled in the waters of Alaska. The data for Alaskan waters includes spills in the Pacific Ocean as well as the Arctic Ocean; therefore, the total amount of oil spilled in United States coastal waters in the range of the ENP gray whale is less than the total of those two amounts. In most years, tank ships, barges, and other vessels accounted for more than half of the total amount of oil spilled nationwide. Processing facilities and pipelines were other major sources of spills (U.S. Coast Guard 2010).

Because of its proximity to Alaska's crude oil supply, Puget Sound is one of the leading petroleum refining centers in the United States, with about 15 billion gallons of crude oil and refined petroleum products transported through it annually (Puget Sound Action Team 2005). Inbound oil tankers carry crude oil to four major refineries in Puget Sound, while outbound tankers move refined oil products to destinations along the United States' west coast (Neel et al. 1997). In 2021, 1,047 oil tankers passed through Washington's waters bound for ports in Puget Sound, Canada, and along the Columbia River (Ecology 2022b). This volume of shipping traffic puts the region at risk of having a catastrophic oil spill. The possibility of a large spill is one of the most important short-term threats to coastal organisms in the northeastern Pacific (Krahn et al. 2002).

Neel et al. (1997) reported that shipping accidents were responsible for the largest volume (59 percent; 3.4 million gallons [12.9 million L]) of oil discharged during major spills in Washington from 1970 to 1996. Other sources were refineries and associated production facilities (27 percent; 1.5 million gallons [5.7 million L]) and pipelines (14 percent; 800,000 gallons [3.0 million L]). Eight major oil tanker spills exceeding 100,000 gallons (378,500 L) have occurred in the state's coastal waters and on the Columbia River since the 1960s, with the largest estimated at 2.3 million gallons (8.7 million L). Grant and Ross (2002) did not report any major vessel spills from British Columbia during this same period, but at least one spill of 100,000 gallons (378,500 L) is known to have occurred in Canadian waters at the mouth of the Strait of Juan de Fuca in 1991 (Neel et al. 1997). In addition to these incidents, numerous near accidents have resulted from vessel groundings, collisions, power loss, or poor vessel condition (Neel et al. 1997).

Between 1995 and 2008, a total of 340,000 gallons (1.29 million L) of petroleum products were spilled in the waters of Washington State (Environmental Research Consulting 2009). More than 80 percent of this resulted from a single event, when 277,000 gallons (1.05 million L) of gasoline spilled from a pipeline in Bellingham in 1999. Most of the remaining total spilled volume came from oil tankers, tank barges, and cargo vessels. Environmental Research Consulting (2009) concluded that, from the perspective of prevention and preparedness, oil tankers represent over 75

percent of the potential risk for worst-case oil discharge, followed by cargo vessels (15 percent of the potential risk), and oil tank barges (6 percent).

Puget Sound's four oil refineries are located on the coast at Anacortes (Shell Oil and Texaco), Ferndale (Mobil Oil), and Tacoma (United States Oil). Four major spills have occurred at two of these facilities, with each causing some discharge of petroleum into marine waters (NMFS 2005d). Pipelines connecting to refineries and oil terminals at ports represent another potential source of coastal spills. Pipeline leaks have caused several major spills in Western Washington, but only the 1999 Olympic spill resulted in any discharge to marine waters (Neel et al. 1997). For a 30-year summary of all major oil spills in Washington, see Ecology (2019).

During the late 1980s and early 1990s, Washington significantly upgraded its efforts to prevent oil spills in response to increased spills in the state and the *Exxon Valdez* accident in Alaska. A number of state, provincial, and federal agencies now work to reduce the likelihood of spills, as does the Makah Tribe and the regional Oil Spill Task Force, which formed in 1989. National statutes enacted in the early 1990s, including the United States Oil Pollution Act in 1990 and the Canada Shipping Act in 1993, have also been beneficial in creating spill prevention and response standards. Since 2008, Washington State has maintained a rescue tugboat at Neah Bay year-round to aid disabled vessels and thereby prevent oil spills. These measures appear to have helped reduce the number and size of spills since 1991 (Neel et al. 1997). For example, in 2010 the Neah Bay emergency tugboat *Hunter* towed the disabled 712-foot container ship *Horizon Tacoma* to the Port of Tacoma after an engine malfunction in the Strait of Juan de Fuca (Gottlieb 2010). This same container ship also lost propulsion in the Strait of Juan de Fuca in October 2011 and was escorted to Port Angeles by the emergency tugboats *Jeffrey Foss* from Neah Bay and *Garth Foss* from Port Angeles (U.S. Coast Guard News 2011). In general, Washington's outer coast, the Strait of Juan de Fuca, and areas near the State's major refineries are the locations most at risk of major spills (Neel et al. 1997). An "area to be avoided" was designated in the OCNMS (Subsection 3.1.1.1.3, Current Issues) to minimize the risk of spills by routing large vessels away from dangerous and sensitive areas. An analysis by NOAA of the effectiveness of the voluntary area to be avoided shows a decrease in the number of commercial vessels transiting the area following the designation. From July through September 1995 (the year in which the area to be avoided was established), 643 vessels transited the area. By 2010, that number had diminished to 61 for the entire calendar year (Ecology 2011).

Chronic small-scale discharges of oil into marine waters from a variety of sources, including tanker ballast waters, ship bilge and fuel oil, and municipal and industrial waste, greatly exceed

the volume released by major spills (Clark 1997) and are another potential impact to gray whales. Though chronic oil pollution has been documented in large numbers of seabird deaths (e.g., Wiese and Robertson 2004), less is known about its impact on gray whales and other marine mammals. The long-term effects of repeated ingestion of sub-lethal quantities of petroleum hydrocarbons on marine mammals are also unknown.

3.4.3.6.5 Offshore Activities and Underwater Noise

Anthropogenic activities in the ocean have increased over the past 50 years, resulting in more underwater noise (Hildebrand 2005; Nowacek et al. 2007). Underwater noise is often regarded as the primary source of disturbance to gray whales (Malme et al. 1988; Moore and Clarke 2002; Richardson et al. 1995; Weller et al. 2006a; Weller et al. 2006b). The types of anthropogenic activities that cause underwater noise within the migratory range of the ENP gray whales include offshore oil and gas development; vessels, including commercial fishing, whale-watching, and scientific research vessels; and training exercises conducted in coastal and offshore waters by the United States Navy. Training activities involve the use of aircraft, marine vessels, submarines, sonar, and explosives. Noise specifically related to whale-watching and other vessel disturbance is described below. A broader discussion of noise (including both atmospheric and underwater noise) in the action area is in Subsection 3.11, Noise, and its effects on wildlife other than gray whales is in Subsection 3.5, Other Wildlife Species.

Gray whale reactions to underwater noise have been relatively well studied compared to those of other mysticetes (Moore and Clarke 2002). Overall, their reactions are variable and influenced by characteristics of the noises they are exposed to (e.g., intensity and temporal pattern of sound) and context of the exposures (e.g., their behavior before the exposure occurred). This section summarizes the results of studies that document a variety of gray whale reactions to a broad range of underwater noises.

Researchers have noted short-term behavioral responses of gray whales to different noises associated with seismic exploration. Malme et al. (1983; 1984; 1988) concluded that continuous broadband sound caused a statistically detectable response in about half of the gray whales exposed to sound levels exceeding approximately 120 decibels (dB re 1 μPa- water standard). The whale response was a brief, slight deflection in migratory course around the sound source. Malme et al. (1984) also found that gray whale response to impulsive sound occurred at received levels 30 to 50 dB more intense than their response to continuous sound. Weller et al. (2006a) found that whales swim away from the noise generated by air guns in seismic surveys off Sakhalin Island, Russia but returned to the areas once the noises ceased. In 2015, a number of

seismic surveys occurred near northeastern Sakhalin Island during the gray whale feeding season, with specific mitigation efforts (Aerts et al. 2022). Gailey et al (2022) found that gray whales exposed to seismic vessels and sounds temporarily changed their movement and respiration patterns, but the biological significance of these behavioral impacts is unknown.

Changes in distribution and acoustic responses were found during playback experiments in San Ignacio Lagoon in 1985 (Dahlheim 1987, reviewed in Schwarz 2002). Most whales abandoned the breeding lagoon apparently in response to the noise, although the whales returned and regularly inhabited this area in subsequent years (Jones et al. 1994).

In addition to altering swimming course and speed, gray whales exhibited abrupt behavioral changes in response to playback sounds and airgun blasts, including switching from feeding to avoidance, with a resumption of feeding after exposure (Malme et al. 1984), and changing calling rates, call structure, and surface behavior, usually from traveling to milling (Dahlheim 1987). Gray whales altered their vocalizations in response to outboard engine and oil drilling sounds, where four different measures of their calls were significantly higher than those measured in experimental conditions (Dahlheim 1987). Whales adapted their calls in response to the noise, essentially "shouting" and calling more frequently to offset the higher noise levels.

A recent study on the Oregon coast found that gray whales had elevated fecal glucocorticoid concentrations, a sign of stress, when more vessels were present the day prior (Lemos et al. 2022). Vessel counts were a significant predictor of underwater ambient noise, suggesting that elevated noise levels may be causing increased stress in the whales, detectable a day later (Lemos et al. 2022).

Technical studies conducted to assess the potential impacts of the U.S. Navy's use of low-frequency active sonar systems investigated the response of baleen whales to low-frequency active sonar signals. The research results confirmed that a portion of the total number of whales exposed to low-frequency active sonar responded behaviorally by changing their vocal activity, moving away from the source vessel, or both, but that the responses were short lived (Department of the Navy 2012). Migrating gray whales avoided exposure to low-frequency active sonar signals when the source was placed in the center of their migration corridor (e.g., Tyack 1999; 2009). In all cases, whales resumed their normal activities within 10s of minutes after the initial exposure to the sonar signal (Department of the Navy 2012).

Malme et al. (1989) prepared a disturbance-ranking scheme for oil and gas noise sources off Alaska. Modeling indicated that gray whales have a high probability of being influenced by noise

from oil and gas operations, including large tankers, dredges, and airgun arrays (Malme et al. 1988), but other studies indicated that the noisiest period of offshore oil and gas operations occurs during exploration and site establishment (Richardson et al. 1995). Production activities are generally quieter and require fewer support operations (Moore and Clarke 2002).

Specific gray whale reactions to whale-watching include changing course and altering their swimming speed and respiratory patterns when followed by whale-watching boats (Bursk 1989), but Jones and Swartz (1984) documented that gray whales in the San Ignacio Lagoon of Baja California become less likely to flee as the season progresses. Mother-calf pairs of gray whales are considered more sensitive to disturbance by whale-watching vessels than other age or sex classes (Tilt 1985). Gray whales also preferentially avoid low frequency active transmissions conducted in a landward direction (Tyack and Clark 1998). Reported gray whale reactions to aircraft vary and seem related to ongoing whale behavior and aircraft altitude (Moore and Clarke 2002).

Gray whale responses to scientific research are described in Subsection 3.4.3.5.3, Whale Response to Being Struck.

Anthropogenic disturbance could potentially lead to energetic loss in gray whales, resulting in fitness and population-level impacts. Bioenergetic models of gray whale energy needs and expenditure can document fitness impacts from lost energy. Under theoretical scenarios, Villegas-Amtmann (2015; 2017) determined the consequences of lost energy intake in gray whales, including survival and reproductive impacts. However, this work has not translated the modeled energetic loss to anthropogenic disturbance. A recent study simulated acoustic disturbance scenarios on gray whale summer foraging grounds in reproductive gray whale females (McHuron et al. 2021). The authors found that spatiotemporal dynamics of disturbance, relating to prey availability, were important factors in the level of individual and population level impacts.

3.4.3.6.6 Vessel Interactions

Whale-watching for gray whales is an important educational and recreational industry and activity along the west coast of North America, from the wintering grounds in the lagoons of Baja California to British Columbia, Canada, although most targeted gray whale whale-watching occurs in the winter range, where tourist boats offer trips to see (and sometimes pet) newly born gray whale calves and mothers. While most commercial whale watching off Washington and British Columbia is directed at killer whales (Hoyt 2001), commercial operations off Washington and British Columbia advertise trips for gray whales along the Pacific coast of Washington (out of Westport and La Push), inside Grays Harbor, the Strait of Juan de Fuca, northern Puget Sound,

and western Vancouver Island, British Columbia. The Oregon coast is a popular whale-watching destination to view members of the PCFG population that utilize the area for their summer feeding grounds. The activity of commercial whale-watching vessels and private recreational boats has raised concerns about its effect on gray whales. In response to these concerns, regulations are in place to minimize disturbance by vessels in Mexico, the United States, and Canada.

In Mexico, the government has applied whale-watching regulations to commercial operators since 1997 (Carlson 2012). There are currently regulations governing the numbers of boats and methods of approach for four specific whale-watching areas in the lagoons. There are no minimum approach distances, but boats cannot chase whales. The northern two-thirds of San Ignacio lagoon closes to whale watching and fishing activities during the breeding and calving season. In the southern third of San Ignacio lagoon (nearest the ocean), whale-watching tourism is closely regulated to allow access to only limited numbers of people (United Nations 1999). In Washington and British Columbia, NMFS and conservation organizations in the United States have teamed up with the Canadian government and conservation organizations to adopt 'Be Whale Wise' guidelines for vessels, kayaks, and other crafts used for watching whales (www.bewhalewise.org; 76 FR 20870, April 14, 2011; Department of Fisheries and Oceans [DFO] Canada 2012a). The guidelines, among other things, recommend that vessels keep a 100-yard (91.4-m) buffer between the vessel and the whale and recommend a slow approach speed of 7 knots within 400 yards (365.8 m) of whales. Washington State law imposes a 300-yard [274-m] approach limit on the side of killer whales, or 400 yards [366 m] in the path of killer whales in Puget Sound, but these regulations do not apply to gray whales.

Whale-watching along the migration route is not heavily regulated, and it has been suggested that this activity, in combination with commercial fishing and vessel operations, may cause gray whales to migrate further offshore (Wolfson 1977). Researchers conducted various studies on the reaction of gray whales to whale-watching vessels in winter on their wintering range and, to some extent, during migration (Urbán-Ramírez et al. 2003). Researchers have paid little attention to the northern portion of the summer range in the Bering Sea and adjacent Arctic Ocean because whale watching is largely undeveloped in those areas (Richardson et al. 1995). One study reported on the reaction of gray whales feeding off Vancouver Island during summer to whale watching vessels (Bass 2000). That study found that the number of vessels had a relatively small influence on gray whale feeding behavior and that effects of vessel presence are more pronounced in shallow water sites. In general, scientists remain cautious about drawing conclusions regarding

the magnitude of the effects of whale watching on gray whales (e.g., Gard 1974; Rice 1975; Reeves 1977; Jones et al. 1994; Urbán-Ramirez and Swartz 2007). That said, findings from a recent study (Sullivan and Torres 2018, discussed below) led to community-developed guidelines for vessels operating near gray whales that would minimize the amount of disturbance experienced by the whales while still maintaining a sustainable local whale-watching industry.

In the winter range, vessels in the lagoons can cause short-term escape reactions in gray whales, especially when boats move erratically or quickly (Ollervides 1997; Reeves 1977; Swartz and Cummings 1978; Swartz and Jones 1978; Swartz and Jones 1981). Bursk (1989) reported that gray whales often changed speed and deviated from their course when near whale-watching vessels. Observers noted that gray whales have also displayed evasive behavior termed snorkeling, where whales came to an almost complete halt to breathe in an inconspicuous manner. Ollervides (1997) found swimming speed decreased and vocalizations changed in response to the presence of boats in Bahia Magdalena. Mosig (1998) reported an inverse relationship between the average number of whale-watching vessels and the average number of gray whales in Laguna San Ignacio in the winter of 1997, but she could not demonstrate any direct effect of vessels on whales. Jones et al. (1994) concluded that whale watching activities were not the cause of the gray whale abandonment of San Ignacio lagoon in the mid-1980s. Observers noted that some gray whales were attracted or showed no response to quiet, idling, slow-moving, or anchored vessels, especially late in winter (Norris et al. 1983; Dahlheim et al. 1984; Jones and Swartz 1984; Jones and Swartz 1986; Richardson et al. 1995). During the course of all these studies, there has been no evidence of long-term impacts of whale-watching vessels on the behavior of gray whales in the lagoons on the wintering grounds (Gard 1974; Jones et al. 1994).

Along the migration route, including the southern portion of the summer range, whale-watching vessels can also cause short-term behavioral reactions in gray whales. Migrating whales disturbed by vessels tended to exhale underwater and surface only long enough to inhale before re-submerging (Hubbs and Hubbs 1967). Observers noted that migrating gray whales also changed course more often with increasing numbers of whale-watching vessels (Bursk 1983; Bursk, in Atkins and Swartz 1988). Heckel et al. (2001) found substantial differences in both speed and direction of the transit of migrating gray whales off Baja California with and without the presence of whale-watching vessels. Similarly, Schwartz (2002) found that gray whales off Point Loma, California, maneuvered to avoid whale watching boats; whales sped up when only one vessel actively followed them and slowed down when more than one vessel was in the vicinity. More recently, a study conducted during the summer of 2015 at two sites off the coast of Oregon found

that gray whales altered their activity budgets, notably the tendency to abandon food searching efforts, when vessels were present within 250 meters (Sullivan and Torres 2018), including motorized tour boats (whale-watching), fishing vessels, recreational, and kayaks. The authors found differences in activity budgets and behavior state transitions across the two sites, suggesting habitat differences (e.g. prey availability or vessel density) and/or variation in disturbance tolerance at different locations (Sullivan and Torres 2018). While these studies show migrating gray whales appear to react to whale-watching and other nearby vessels, there is no other evidence to suggest the whales have altered the location of their migration route due to their presence.

Whale-watching vessels regularly approach gray whales feeding in Clayoquot Sound, on the west coast of Vancouver Island, British Columbia, during summer. Whales responded to the vessels by changing their dive patterns by surfacing more frequently. While these changes appeared to be temporary when the vessels were present, these findings suggested some loss of foraging time for the whales (Bass and Duffus 1999; Bass 2000).

There have been two cases where it has been speculated that vessels and noise, in combination with other factors, may have affected long-term gray whale distribution. Between 1975 and 1978, aerial surveys by Dohl and Guess (1979) showed that about 60 percent of gray whales were using migration routes farther offshore than the coast routes they had traveled previously. They concluded that it was the result of an increase in the overall population of gray whales. Between 1964 and 1983, seismic activity in this region was substantial (Malme et al. 1984), but many suggest that increases in noise and vessel traffic in this region were the cause (Rice 1965; Hubbs and Hubbs 1967; Wolfson 1977; Schulberg et al. 1989 and 1991, as cited in Richardson et al. 1995; Mate and Urbán-Ramirez 2003). The second case focused on gray whales feeding in Clayoquot Sound off Vancouver Island. Duffus (1996) demonstrated a sequential increase in gray whale foraging locations away from the major whale-watching port of Tofino over a 3-year period. While it was not possible to determine if the whale watching vessels contributed to or caused this shift in gray whale distribution, Duffus suggests a risk-averse management approach to regulating vessel traffic in gray whale feeding areas.

Although the gray whale population is exposed to whale-watching vessels and other disturbances on the wintering grounds and along much of the migration route, it has demonstrated a tolerance and resiliency to whale-watching and other noisy human activities as reflected by the successful recovery of the population from over-exploitation (Cowles et al. 1981; Moore and Clarke 2002).

3.4.3.6.7 Activities Occurring in the Mexican Portion of the Range

Much of the coastal area surrounding the Baja lagoons and the gray whale wintering range is protected by law and limited access. In 1988, the Mexican government established El Vizcaino Biosphere Reserve, an area totaling 2,546,790 acres and encompassing Ojo de Liebre (Scammon's Lagoon), Guerreo Negro, and the San Ignacio Bay gray whale sanctuaries. Portions of the reserve, including San Ignacio and the Ojo de Liebre lagoons, were designated as United Nations Educational, Scientific, and Cultural Organization world heritage sites in 1993 (Urbán-Ramírez et al. 2003). In 2005, the Bay of Loreto National Marine Park, in the northern area of the Sea of Cortez, joined the list. In May 2002, all Mexican territorial seas and the EEZ were declared as a refuge for the protection of large whales. See Urbán-Ramírez et al. (2003) for additional information on formal protection of gray whales in Mexico. Whale watching is discussed above in further detail; other activities in the winter range that have been identified as future environmental concerns by ParksWatch of Mexico are discussed below.

Mineral and Salt Mining

Mining for minerals (such as copper, manganese, gypsum, cobalt, silica, and phosphorus) peaked in the last century in places like Santa Rosalia, creating soil erosion, contamination, pollution, and litter in the ocean. Large mining companies have since abandoned these sites, and the town is in economic decline (ParksWatch 2004). The largest saltworks in the world is, however, still operating at Guerrero Negro, where approximately 8 million tons (7.26 million metric tons) per year is extracted from the ocean through evaporation (ParksWatch 2004). The main threat posed by salt mining is the byproducts created by high salt concentrations (Geo-Mexico 2012).

In 1995, two large corporations proposed to expand industrial salt extraction by establishing a plant on the shores of San Ignacio Lagoon, Mexico. International and national concern arose as to whether the then-proposed salt plants would divert fresh water from pumping, produce and discharge toxic brine and other water-based pollutants into the lagoon waters, and spur further development, among other issues, potentially having adverse effects on the ecosystem and gray whales (e.g., Sullivan 2006). At the 52nd meeting of the IWC, Urbán-Ramírez (2000) reported the results of a study on the proposed saltworks project. In particular, he evaluated potential impacts on the gray whales that use this wintering area for breeding, calving, and calf rearing. According to his study results, the salt facility in San Ignacio would not harm gray whales. Nonetheless, on March 2, 2000, the government of Mexico cancelled the saltworks project. Conservation agreements negotiated between the Laguna San Ignacio Conservation Alliance and communal landowners have since placed 120,000 acres of land around the lagoon in a private

land trust, and more agreements are anticipated (Sullivan 2006). Thus, while the local people fish and provide ecotourism and whale-watching, it is reasonable to assume that the area will remain a sanctuary for wintering gray whales (Sullivan 2006).

Shore-Based Commercial Development in Bahia Magdalena

The growth of gray whale tourism in the North Zone of Bahía Magdalena led to a proposed Japanese-owned and financed tourist resort development at Bahía Magdalena (Dedina and Young 1995). Although NMFS identified this activity as a potential threat to the whales and their habitat in its 1999 gray whales status review (e.g., water quality degradation, increase in whale-watching tourism, etc.), there are currently no plans to proceed with this development (Rugh et al. 1999). In response to the popularity of whale watching as a tourist activity, local communities around Bahía Magdalena have developed local inns, guesthouses, and restaurants (Hoyt and Iñíguez 2008). No information is available about any proposals for large-scale shore-based commercial development in the area.

3.4.3.6.8 Ship Strikes

The nearshore migration route used by gray whales makes ship strikes a potential source of injury and mortality (Laist et al. 2001; Silber et al. 2021). Anecdotal data and strandings recorded by the Marine Mammal Stranding Network provide helpful, but incomplete, data on the occurrence, frequency, and significance of vessel-related whale deaths and injuries (Laist et al. 2001). Laist et al. (2001) suggests that most lethal or severe injuries are caused by large ships 263 feet (80 m) or longer and by ships traveling 14 knots or faster. From 1975 to 1980, there were reports of 12 collisions and 6 confirmed deaths of gray whales off the coast of southern California, and 7 of 489 gray whales stranded between Mexico and Alaska from 1975 to 1989 had apparent propeller injuries (Laist et al. 2001). Ferrero et al. (2000) reported five gray whale mortalities off California from ship strikes from 1993 to 1995, and one ship-strike mortality occurred off Alaska in 1997. Between 1999 and 2003, the California Marine Mammal Stranding Network reported four serious injuries or mortalities of gray whales caused by ship strikes, one each in 1999, 2000, 2001, and 2003 (Angliss and Outlaw 2005).

Based on the photo-identification catalog maintained for gray whales in the winter range, Urbán-Ramírez et al. (2003) reported that an estimated 2 percent (then about 1,600) of the whales had injuries (scars) from impact with a large keel or propeller. Additional mortality from ship strikes probably goes unreported because the carcasses sink at sea (i.e., the whales do not strand), the beached carcasses do not show obvious signs of ship strikes or the whales may not die when hit (Urbán-Ramírez et al. 2003). It is impossible to quantify the actual mortality of gray whales from

this source, and an annual mortality rate of one or two gray whales per year from ship strikes represents a minimum estimate (Scordino et al. 2020; Silber et al. 2021; see also Rockwood et al. 2017). Consistent with that estimate, Carretta et al. (2023) reported that for the most recent 5-year period, 2014-2018, the total serious injury and mortality of ENP gray whales attributed to ship strikes was 9 animals, or 1.8 whales per year. Most of these reported strikes occurred in California, while two occurred in Washington and two in Oregon. Seven of the whales were reported as dead, while the remainder were reported as having a serious injury. The total serious injury and mortality of gray whales due to vessel strikes in the area used by PCFG whales (based on season and range) during this same period was three animals (i.e., equivalent to 0.6 whales per year). A recent study mapped out vessel traffic density in the north Pacific to assess the overlap gray whale migration, wintering, and feeding grounds (Silber et al. 2021). The authors found the greatest risk of vessel strikes to occur during the migration route when gray whales are closer to shore and coinciding with larger shipping vessels, although commercial fishing also posed a risk (Silber et al. 2021).

3.4.3.6.9 Incidental Catch in Commercial Fisheries

Most data on human-caused mortality and serious injury of gray whales is from strandings (including at-sea reports of entangled animals alive or dead). Strandings represent only a fraction of actual gray whale deaths (natural or human-caused). Punt and Wade (2012) estimated that 3.9 to 13.0 percent of gray whales that die in a given year strand and are reported. Since 1978, a total of 12 entangled gray whales have been reported within the Makah U&A (NMFS 1995; Scordino and Mate 2011; NMFS 2013a; Carretta et al. 2014; Carretta et al. 2020). Of the gray whales entangled in the past 30 years, only one is known to have died and been used by the Tribe (NMFS 1995).[67] When entangled whales are sighted in the Makah U&A, tribal biologists typically work with other researchers and agencies (e.g., NMFS and the Cascadia Research Collective) to disentangle the animals. The Makah Tribe has assisted in several disentanglement efforts, including helping with two humpback whales in 2008 and 2010 (Cascadia Research Collective 2008; Cascadia Research Collective 2010a) and the successful disentanglements of gray whales in 2009 and 2013 (NMFS 2013a).

[67] In 2018, a humpback whale was killed by a ship strike and subsequently harvested for ceremonial and subsistence purposes. This is the only other time a stranded whale has been used by the Makah Tribe in the last 30 years. See https://www.seattletimes.com/seattle-news/whale-killed-by-ship-near-neah-bay-now-a-harvest-celebration-as-makah-nation-prepares-feast/.

NMFS recognizes 15 commercial fisheries in California, Oregon, Washington, and Alaska that use gillnet, trawl, or pot gear and that have caused incidental serious injuries or mortalities of gray whales (87 FR 55348, September 9, 2022). Serious injuries or mortalities have occurred in the Bering Sea, Aleutian Islands flatfish trawl and crab pot fisheries, as well as several pot fisheries in California, and the Dungeness crab pot fishery in Oregon and Washington.

Several Alaska and California set and drift gillnet fisheries have also caused gray whale mortalities or serious injuries. There have been five observed entanglements in the California/Oregon thresher shark/swordfish drift gillnet fishery from 1990-2018, including one from the most recent 5-year period of 2014-2018 (Carretta et al. 2023). In the more coastal California set gillnet halibut fishery there have been no observed entangled gray whales for the same time period, but there have been recent sightings of free-swimming gray whales entangled in gillnets (Carretta et al. 2023). NMFS observers monitored the Makah tribal set gillnet fishery from 1990 to 1998 and in 2000, reporting one gray whale taken in 1990 and one in 1995. One gray whale was entangled in a set gillnet during the 1995 fishery and was used by the Tribe after it died (NMFS 1995); another whale entangled in the 1996 fishery was released alive (Hill and DeMaster 1998).[68] In recent years, this set gillnet fishery has been reduced considerably and is currently restricted to the Strait of Juan de Fuca (Makah Fisheries Management 2012). Because of a lack of observer programs, mortality data from Canadian commercial fisheries is not available. Baird et al. (2002) estimated the annual mortality in Canadian fisheries to be approximately two whales.

Carretta et al. (2023) summarized the human-caused mortality and serious injury resulting from unknown fishery sources (predominantly pot/trap or net fisheries) for the most recent 5-year period of 2014 to 2018. Total observed human-caused fishery mortality and serious injury due to entanglement for ENP gray whales during this period was 9.3 whales per year. Total observed human-caused fishery mortality and serious injury due to entanglement in the area used by PCFG whales (based on season and range) for the same period was 1.1 whales per year.

3.4.3.6.10 Marine Energy Projects

Hydrokinetic projects generate electricity from waves or directly from the flow of water in ocean currents, tides, or inland waterways. Broadly, the technologies developed for this purpose are

[68] Another gray whale was found entangled in a tribal set gillnet in 2009 and swam away during disentanglement attempts (Scordino and Mate 2011; Carretta et al. 2014).

categorized as wave energy converters (e.g., buoys that translate vertical motion into energy) or rotating devices (e.g., underwater turbines).

WDFW (2006b) identified preliminary potential impacts of such projects to birds, fish, and marine mammals. They include, but are not limited to, direct mortality or injury from turbine blade strikes, interference with migratory patterns, measures to protect equipment from marine growth, direct habitat loss from equipment and infrastructure placement, impacts on currents, changes in water surface elevations, effects on commercial and recreational fishing areas and equipment, changes in sediment transport, and other issues not yet identified.

In December of 2007, FERC issued a license for a pilot wave energy project in Makah Bay, located in the Makah U&A andwithin the gray whale's migratory corridor. In 2009, the licensee surrendered the license, stating that the project had become uneconomical (HydroWorld 2009). In addition to this project, there are at least 30 others originally considered for placement along the Washington, Oregon, and California coasts that are now classified as defunct (PFMC 2013).

In August 2012, the Federal Energy Regulatory Commission (FERC 2012) issued a 35-year license for a 10-buoy, 1.5-megawatt wave energy project approximately 2.9 miles (4.6 km) off the Pacific coast near Reedsport, Oregon. In a review of the project, NMFS (2012b) determined that construction and installation of the buoy array would not result in any harassment or take of marine mammals that may be found in the area and are listed under the Endangered Species Act (specifically Southern Resident killer whales and humpback whales). In 2013, the licensee (Ocean Power Technologies) announced that the Reedsport project was being suspended because of regulatory, financial, and other considerations (Ocean Power Technologies 2013), and the project was abandoned in 2014 (Hunt and Cardwell 2014).

In March 2014, the FERC issued a 10-year pilot license for a proposed 600-kilowatt tidal project to be located in Puget Sound's Admiralty Inlet (FERC 2014). The project was intended primarily to be a research site to assess the commercial viability of tidal energy generation (using two tidal power turbines) and expected to operate for just 3 to 5 years. In reviewing the project, NMFS (2013b) determined that the proposed action was not likely to jeopardize the continued existence of ESA-listed marine species (including Southern Resident killer whales and humpback whales) nor likely to result in the destruction or adverse modification of designated critical habitat. In that review, NMFS also noted that any future development of this tidal energy project beyond the 10-year license period would be subject to separate review and authorizations. However, in September 2014, the project was cancelled due to funding constraints (Snohomish Public Utilities District 2014).

As of January 2023, there is only one FERC-licensed hydrokinetic project on the U.S. West Coast (FERC 2023). PacWave South Hydrokinetic (formerly known as Pacific Marine Energy Test Center South Energy Test Site Wave Test Center) is located on the Outer Continental Shelf of the Pacific Ocean, approximately 6 nautical miles off the coast of Newport, Oregon. In 2021, the Bureau of Ocean Energy Management (BOEM) issued a lease of the site to Oregon State University for marine hydrokinetic research activities at a proposed open ocean wave energy test center (86 FR 40620, July 28, 2021). FERC issued a license to Oregon State University for the construction, operation, and maintenance of the proposed test facility that would have a capacity of 20 megawatts. The PacWave South license is valid through February 2046. A second site, PacWave North, also operated by Oregon State University off the coast of Newport, Oregon, serves as a test site for small-scale, prototype technologies and is not grid-connected[69].

While there are several active preliminary permits under FERC for hydrokinetic projects in inland waters of Alaska (which allow developers to study the feasibility of proposed projects), there are no active or pending preliminary permits for projects on the coasts of Washington, Oregon, or California (FERC 2023) where gray whales could potentially travel.

3.4.3.6.11 Climate Change and Ocean Acidification

There is growing evidence indicating that the Arctic climate is changing significantly, and these changes are likely to directly or indirectly affect marine mammals. For example, Wang and Overland (2009 and 2012) reviewed several climate models to predict that the Arctic could be nearly free of summer sea ice sometime in the 2030s. As reported in the most recent NMFS stock assessment report (Carretta et al. 2023), this change in the Arctic ecosystem will impact, or already is impacting, gray whales. With past increases in numbers of gray whales (Rugh et al. 2005), in combination with changes in prey distribution (Grebmeier et al. 2006; Moore et al. 2007) and a reduction in the extent of sea ice cover in some regions (Johannessen et al. 2004), some gray whales have moved into new feeding areas, spreading their summer range (Rugh et al. 2001). These changes may also result in major mortality events (Stewart et al. 2023). Laidre et al. (2008) surmised that for gray whales and other species that feed in the Arctic during the summer, animals may start to arrive farther north at progressively earlier dates and compete directly with those species that live year-round in the Arctic. These authors developed an index of sensitivity of Arctic marine mammals to climate-induced change; species that were most sensitive included

[69] See https://pacwaveenergy.org/ for more information.

those that relied on sea ice and specialized feeding adaptations, such as polar bears, walrus, and narwhals. Gray whales are considered to be more opportunistic foragers (Moore and Huntington 2008), and projected short-term impacts on them are equivocal (Ragen et al. 2008).

Bluhm and Gradinger (2008) examined the availability of pelagic and benthic prey in the Arctic and concluded that pelagic prey is likely to increase while benthic prey is likely to decrease in response to climate change. They noted that marine mammal species that exhibit trophic plasticity (such as gray whales, which feed on both benthic and pelagic prey) will adapt better than trophic specialists. Moore and Huntington (2008) assessed the impacts of climate change on the resilience of Arctic marine mammals and observed that "gray whales are perhaps the most adaptable and versatile of the mysticete species" (but see Stewart et al. (2023)). They further noted that gray whales are dynamic and opportunistic foragers and cited recent and unexpected observations that some animals remain in northern waters (including the Beaufort Sea) year round. In their review of reported climate change impacts on gray whales, Salvadeo et al. (2013) cited the following as likely gray whale responses to global warming:

- Fewer whales in the Gulf of California.
- Increased numbers of mothers with calves along the California coast.
- Winter occurrence of whales on their feeding areas.
- Recolonization of the Atlantic Ocean by gray whales.
- Decrease in whale numbers in the breeding lagoons.

Several of these predictions have been realized in recent years coinciding with the current UME, including fewer whales in the Gulf of California, reduced number of whales in the breeding lagoons (LSIESP 2023), and shifting occurrence in feeding areas (Moore et al. 2022; Joyce et al. 2023).

Rising levels of carbon dioxide are expected to increase ocean acidification which in turn could also cause changes in the abundance and types of shell-forming organisms[70] (Fabry et al. 2008; Hall-Spencer et al. 2008), many of which are important in the gray whales' diet (Nerini 1984; Moore and Huntington 2008). Atmospheric carbon dioxide levels are currently rising at a rate roughly 100 times faster than at least the past 420,000 years, and approximately half of the anthropogenic CO_2 produced in the past 200 years has been absorbed by the oceans (Royal Society 2005). In 2005, the Royal Society convened a working group of international experts to

[70] The reaction of carbon dioxide with seawater reduces the availability of carbonate ions that calcifying prey organisms like amphipods need to create shells.

produce a report on ocean acidification as a result of increasing atmospheric carbon dioxide. One of the main conclusions regarding impacts on marine species was that:

> *"Organisms will continue to live in the oceans wherever nutrients and light are available, even under conditions arising from ocean acidification. However, from the data available, it is not known if organisms at the various levels in the food web will be able to adapt or if one species will replace another. It is also not possible to predict what impacts this will have on the community structure and ultimately if it will affect the services that the ecosystems provide. Without significant action to reduce CO_2 emissions into the atmosphere, this may mean that there will be no place in the future oceans for many of the species and ecosystems that we know today. This is especially likely for some calcifying organisms."*

Global climate change is also likely to increase human activity in the Arctic as sea ice decreases, including oil and gas exploration and shipping (Hovelsrud et al. 2008). Such activity will increase the chance of oil spills and ship strikes in this region. Gray whales have demonstrated avoidance behavior to anthropogenic sounds associated with oil and gas exploration (Malme et al. 1983; 1984; Gailey et al. 2022) and low-frequency active sonar during acoustic playback experiments (Buck and Tyack 2000; Tyack 2009). Some oceanographers (Hester et al. 2008; Brewer and Hester 2009) have reported that an unanticipated consequence of ocean acidification is a significant decrease in sound absorption because of various chemical interactions, in particular those involving forms of boron. The result is a "noisier ocean" where sounds travel farther, especially low frequency sounds used by marine mammals. These researchers reported that sound already may be traveling 10 percent farther in the oceans than it did a few hundred years ago and that it remains to be seen how marine mammals will adapt to the greater background noise. In contrast to these reports, subsequent modeling by Udovydchenkov et al. (2010) yielded results indicating that changes may be minimal; a few decibels of increase may occur in 100 years in some very quiet areas very far from noise sources, with small effects closer to noise sources.

In a recent review, Gulland et al. (2022) identified several impacts of climate change on marine mammals in U.S. waters, including fitness, ecological, and health impacts. While the review did not identify any studies that predicted climate effects on gray whales in U.S. waters, the authors did compile recent observational data reported by various researchers that suggests a climate link to gray whale body condition, mortality, and calf production (Gulland et al. 2022).

Recent work has identified that climate variables and sea ice cover are important predictors of gray whale distribution, phenology, and population dynamics. For example, Perryman et al.

(2021) found that the variability in calf production can be explained by climate indices and sea ice cover in the northern feeding grounds (Bering and Chukchi Seas) experienced by gray whales in the preceding year. In years with high sea ice cover in spring/early summer, northbound calf counts were lower the following year, suggesting access to prey during early gestation could be mediating this relationship (Perryman et al. 2021). Gailey et al. (2020) found a similar pattern for WNP gray whales in their feeding grounds off Sakhalin Island.

Gray whale abundance and distribution in northern feeding grounds also varies with sea ice cover and prey abundance. In a recent analysis, Joyce et al. (2023) found a negative relationship between gray whale counts and ice concentration in the northeast Chukchi Sea, along with absence in foraging hot spots during years with delayed ice break-up and during periods of dense ice cover. Further, the authors found that the onset of acoustic detection of gray whales had a strongly positive relationship with ice break-up date, meaning that gray whales arrive later to the foraging grounds when sea ice break-up is later (with a model-estimated lag time of 10-15 days) (Joyce et al. 2023). In various locations throughout the Bering and Chukchi Seas, Moore et al. (2022) found that gray whale calls were associated with winter sea ice retreat, and that gray whale distribution correlated with prey abundance and wind patterns that influence prey abundance.

Previous work has suggested that sea ice coverage prevents gray whales from accessing foraging habitats within the Pacific Arctic feeding grounds (Gailey et al. 2020; Perryman et al. 2021), thus delaying access to important infaunal and benthic prey following a long migration period during which limited feeding occurs (and resulting in reduced calf production; see above). Joyce et al. (2023) note, however, that there are significant departures from this trend. These include: a) calf production in 2013-2014 was high despite relatively high sea ice cover in the preceding years, and b) calf production in 2021 was relatively low (Stewart and Weller 2021b) despite very low sea ice cover. Joyce et al. (2023) posit an alternative, non-mutually-exclusive hypothesis, that suggests the lag between sea ice break-up and arrival at foraging hot spots allows for nutrient uptake by prey prior to consumption by gray whales. Further, as described in Subsection 3.4.3.3.4, ENP Status, Carrying Capacity, and Related Estimates, Stewart et al. (2023) found that both sea ice cover and crustacean biomass affect gray whale population dynamics, suggesting that sea ice cover is mediating a relationship between benthic prey communities and higher trophic level foragers.

While no studies have found a direct link between climate change and adult gray whale mortality, some have proposed that the ongoing UME is due to climate-related factors mediated by prey availability (also see Stewart et al. (2023)). Post-mortem studies of gray whale strandings from

the UME that was declared in 2019 have been equivocal, however. Raverty et al. (2020) and Fauquier et al. (2023) documented that some gray whales that stranded during 2019-2021 were emaciated or thin (16 whales with emaciation as the only postmortem finding out of 61 whales evaluated), although other causes of death were identified as well including vessel strikes (11 whales), predation (3 whales), and entanglement/entrapment (3 whales). Photogrammetry studies of gray whales in wintering lagoons in Mexico found elevated numbers of whales in poor body condition during early years of the UME (and the year prior) as compared to 2017 (Christiansen et al. 2021), which may have fitness-level effects. Additionally, the body condition of PCFG whales in Oregon during this same time period (2017-2019) appeared to have improved (despite the PCFG having overall lower body condition than whales wintering in Mexico) (Torres et al. 2022), providing more support for climate-related effects on ENP gray whale prey in the Pacific Arctic feeding grounds.

3.4.3.6.12 Marine Debris

A substantial body of evidence documents the negative effects of marine plastic debris on marine life, including whales (EPA 2011b; IWC 2013b). In 2013, 2014, and 2019, the IWC held Marine Debris Workshops to address the impacts of marine debris on cetaceans and their habitat (IWC 2013b; 2014d; 2020). ENP gray whales were one of three species considered a priority for research to determine the severity and location of impacts on individual whales and whale populations.

The most common threats of marine debris to whales are ingestion of and entanglement (EPA 2011b) in debris that has settled on the sea floor or accumulated at or near the water's surface. Gray whales can ingest debris while foraging or swimming. For example, a gray whale that stranded in West Seattle in April 2010 was found to have ingested a variety of manmade objects, including plastic bags, small towels, surgical gloves, sweat pants, plastic pieces, duct tape, and a golf ball (Cascadia Research Collective 2010b), but is not known if the items contributed to the death of the whale. Foraging gray whales can also inhale low-density plastics that become airborne at the water's surface (IWC 2013b). Problems associated with the ingestion of plastics by whales include the development of internal and external wounds, impairment of feeding capacity because of the buildup or blockage of the digestive system, decreased mobility and predator avoidance, and toxicity (Gregory 2009; EPA 2011b; IWC 2020).

Plastic debris in particular is a widespread problem, making up 50 to 80 percent of beach litter, floating marine debris, and waste on the sea floor (Barnes et al. 2009). In 2012, more than 300 million tons of plastic were produced globally, less than half of which was recycled or consigned

to landfills (Rochman et al. 2013). Large patches of plastic debris have been observed in the North Pacific Ocean where currents form a gyre that collects floating materials (EPA 2011b). Studies based on satellite-derived information and ocean circulation models, and confirmed by flight observations, show that the largest debris concentration in the North Pacific occurs along a southwest-to-northeast line north of the Hawaiian Islands between 23° N and 37° N latitude (EPA 2011b) and is accumulating plastics more rapidly than previously thought (Lebreton et al. 2018). The distribution of marine debris is dependent on the distribution of sources of the debris (e.g., urban areas, tourist beaches, shipping routes, fishing grounds) and oceanographic processes (Howell et al. 2012; IWC 2013b). For example, microplastics (i.e., plastic particles smaller than 0.04 inch [1 mm]) are 2.5 times more abundant in coastal marine areas that receive sewage than areas that do not (Browne et al. 2011). A recent study quantified microparticle loads in gray whale prey and fecal matter off the Oregon coast (Torres et al. 2023). While estimated daily consumption rates of microparticles were high, toxicity and health consequences are unknown.

The potential toxicity of plastic debris is a growing concern (NOAA 2023). Pollutants in seawater adhere to and become concentrated on small particles of plastic (Ashton et al. 2010; Rios et al. 2010; Andrady 2011), which can subsequently be ingested or inhaled by whales. Mato et al. (2001) found the concentration of PCBs on plastic resin pellets to be 100,000 to 1,000,000 times that of surrounding waters. Other pollutants that may be concentrated on plastic debris include polyethylene, polypropylene, phthalates, and other persistent organic pollutants (IWC 2013b; 2019). Persistent organic pollutants are synthetic organic compounds that have a wide range of chronic effects, including endocrine disruption, mutagenicity, and carcinogenicity (Rios et al. 2007). Furthermore, these pollutants are chemically stable, meaning they are not easily degraded in the environment or in organisms (Rios et al. 2007). The impacts on baleen whales of ingesting toxins in plastic debris are largely unknown (IWC 2020). However, the presence of phthalates in the blubber of stranded fin whales in the Mediterranean Sea provides evidence for the consumption and metabolism of plastics by cetaceans (Fossi et al. 2012; IWC 2013b).

In addition to ingesting or inhaling small particles of marine debris, gray whales can become entangled in larger debris. Debris such as derelict fishing gear (e.g., nets, rope, monofilament fishing line, traps, pots, floats, buoys) can entangle and injure animals or interfere with their ability to pursue food. As noted in Subsection, 3.4.3.6.9, Incidental Catch in Commercial Fisheries, and Subsection 3.10.3.5.2, Makah Subsistence Consumption, gray whales encounter and sustain injury from a variety of fishing gear, including derelict gear. Gray whales and humpback whales are the most commonly reported entangled large whale species along the U.S.

west coast (IWC 2013b; Saez et al. 2013; NMFS 2022a). Whale entanglements on the U.S. west coast are reported from opportunistic on-water sightings (e.g., NOAA's 1-800-SOS-Whale reporting hotline), stranding records, and commercial fishery observers, but there is no formal reporting infrastructure for entanglements (IWC 2013b). As a result, and in light of the cryptic nature of entanglement events, the numbers of entanglements are likely underreported (Read et al. 2006; IWC 2013b). Based on reported observations of mortality and serious injury from entanglement in fishing gear from 2014 to 2018, Carretta et al. (2023) reported that 2 gray whales were killed or seriously injured from marine debris entanglements, or an estimated 0.4 deaths or serious injuries each year. Some of the strandings (see in Subsection 3.4.3.1.7, Strandings), may be related to marine debris, but the cause of death for most stranded whales is unknown. Notably, 48 marine mammals were found dead in derelict gillnets recovered from Puget Sound and the U.S. portions of the Strait of Juan de Fuca and Strait of Georgia from 2002 through 2013, none were gray whales (Northwest Straits Foundation 2013).

On March 11, 2011, a devastating 9.0 earthquake and tsunami struck Japan, causing significant loss of life and property and washing out an estimated 5 million tons of debris into the North Pacific Ocean. While most of the debris sank near Japan, approximately 30 percent floated away and 635 metric tons of debris was removed from the shores of Alaska, Hawaii, Washington, Oregon, and California over the next several years (NOAA 2013; 2022). There have been approximately 1,900 debris sighting reports coming to the NOAA reporting and tracking system, with 67 percent of reports from shore-based observations (NOAA 2015). Several items found have confirmed connections to the Japan tsunami, including vessels, buoys, sports balls, floating piers, and a motorcycle in a container. Other types of debris that could wash up include buoyant items, such as fishing nets, lumber, or cultural items. Because marine debris is a persistent problem originating from many sources around the Pacific, it's very difficult to tell where debris came from without unique identifying information.

3.5 Other Wildlife Species

3.5.1 Introduction

Various marine mammals and birds inhabit the action area, with the highest use during late spring through early fall and the lowest use during winter (NOAA 1993). Thirty species of marine mammals and 109 species of marine birds have been recorded in the action area (NOAA 1993). Of these species, nine mammal species (Guadalupe fur seals, Southern Resident killer whales, WNP gray whales, Central America and Mexico DPS humpback whales, sperm whales, fin whales, blue whales, sei whales, and North Pacific right whales) (Table 3-16) and two bird

species (marbled murrelets and short-tailed albatross) are listed under the ESA as threatened or endangered. Four federally listed reptiles (leatherback sea turtles, green sea turtles, loggerhead sea turtles, and olive ridley sea turtles) also can occur in the area (Plotkin 1995). One marine mammal (sea otter) not listed under the federal ESA is listed as endangered by Washington State.

3.5.2 Regulatory Overview

Various federal, state, and local regulations address the protection of threatened, endangered, and sensitive wildlife in the action area. Table 3-15 lists regulations for wildlife. In most cases, city and county regulations reflect WDFW recommendations. For a detailed description of NMFS' management of marine mammals (including, but not limited to, gray whales), see Subsection 3.4.2.1, Marine Mammal Protection Act Management.

With regard to disturbance of marine wildlife, MMPA prohibits (with some exceptions) the harassment of marine mammals in U.S. waters. The 1994 amendments to the MMPA defined harassment (Level B) as any act of pursuit, torment, or annoyance that has the potential to disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering. Loud, continued noises could be considered harassment to wildlife, particularly to marine mammals that use sound to communicate.

To protect nesting seabirds and marine mammals from noise and physical disturbance from low-flying aircraft, OCNMS prohibits flying motorized aircraft less than 2,000 feet (610 m) over certain areas of the Sanctuary. These restrictions are described in greater detail in Subsection 3.1.1.1.2, Designation [of the OCNMS] and Regulatory Overview. The restrictions were finalized with a final rule published by NOAAion (77 FR 3919, January 26, 2012). In addition, the Sanctuary has made increasing voluntary compliance with this regulation a major priority (Galasso 2005). Notably, data collected by University of Washington researchers studying marine birds at Tatoosh Island were used to conduct an enforcement action against a helicopter pilot and contracting passenger (Parrish et al. 2005).

Table 3-15. Federal, state, and local regulations for protected wildlife.

Regulation	Overseeing Agency	Wildlife Species and Habitats Addressed
Federal		
Marine Mammal Protection Act (MMPA)	NMFS and USFWS	All marine mammal species. See Subsection 1.2.3, Marine Mammal Protection Act, for a description of the MMPA.
Whaling Convention Act (WCA)	NMFS	All cetacean species. See Subsection 1.2.4, Whaling Convention Act, for a description of the WCA.
Endangered Species Act (ESA)	USFWS and NMFS	All federally listed threatened and endangered species and critical habitats. Federal agencies must ensure that any action they authorize, fund, or carry out is not likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of designated critical habitat.
Migratory Bird Treaty Act and Executive Order 13186	USFWS	Most migratory birds. The act provides that it is unlawful to pursue, hunt, take, capture, or kill these birds.
Bald Eagle Protection Act and Eagle Protection Act	USFWS	Bald eagle (and golden eagle). The act prohibits the taking or possession of and commerce in bald and golden eagles, with limited exceptions.
Olympic Coast National Marine Sanctuary regulations, 15 CFR Part 922, Subpart O	NOAA, National Marine Sanctuary Program	Marine mammals, sea turtles, seabirds, and their habitats. The regulations prohibit take of these wildlife, except as authorized by the ESA, MMPA, Migratory Bird Treaty Act, or pursuant to any relevant Indian treaty, provided that the treaty is exercised in accordance with the ESA, MMPA, and Migratory Bird Treaty Act, to the extent that they apply. These regulations prohibit flying motorized aircraft at less than 2,000 feet (610 m) elevation both above the sanctuary and within 1 nautical mile (1.9 km) of the Flattery Rocks National Wildlife Refuge or within 1 nautical mile (1.9 m) seaward from the coastal boundary of the sanctuary, with limited exceptions.
State		
Washington State Endangered Species Act, Washington Administrative Code 232-12-297	WDFW	All state-listed threatened, endangered, and 'state sensitive' species. Associated recovery plans provide guidelines on management of these species.
Local		
Clallam County Critical Areas Ordinance No. 709, 2001	Clallam County	Habitat for threatened, endangered, and other sensitive species. Provides general guidance. Also provides specific buffers for bridge construction and other projects that are not relevant to the action alternatives.

3.5.3 Existing Conditions

The following discussion is divided into three primary topics. It focuses on establishing a baseline of information for addressing issues of concern including noise, disturbance, and other perturbations that may affect marine wildlife. Subsection 3.5.3.1 describes the marine mammal species that are known to occur in the action area. Subsection 3.5.3.2 provides an overview of other marine wildlife species in the action area. Both sections address ESA-listed species as well as other species in the action area. Subsection 3.5.3.3 discusses the sensitivity of marine mammals and other wildlife species to noise and other disturbance both above and below the surface of the water.

3.5.3.1 Marine Mammals

Table 3-16 lists 30 species of marine mammals that breed within, rest within, or migrate through the waters off the Washington coast (NMFS 1992b; NOAA 1993). Descriptions of state and federal threatened or endangered species followed by common and then, to a lesser extent, uncommon species are provided in this section. Full descriptions of these species are in Young et al. (2023), Carretta et al. (2023), Haley (1986), Perrin et al. (2002), and Nowak et al. (2003), with specific information on their use off the Washington coast by Brueggeman et al. (1992), Calambokidis et al. (2004b), Green et al. (1993), Jeffries et al. (2012), and Oleson et al. (2009).

Table 3-16. Marine mammals that occur along the Washington coast and their federal/state status.

Species	*Scientific Name*	Occurrence	Primary Habitat	Primary Prey	Season(s) Present	Federal/ State Status
Harbor seal	*Phoca vitulina*	Common	Coastal/ continental	Fish	Year-round	
California sea lion	*Zalophus californianus*	Common	Coastal/shelf	Fish	Summer/ spring	
Steller sea lion	*Eumetopias jubatus*	Common	Coastal/shelf	Fish	Year-round	Federally delisted
Northern elephant seal	*Mirounga angustirostris*	Common	Shelf/slope	Fish/squid/ crab	Summer/fall	
Northern fur seal	*Callorhinus ursinus*	Common	Offshore/ slope	Fish/squid	Year-round	Federally depleted
Guadalupe fur seal	*Arctocephalus townsendi*	Uncommon	Offshore/ slope	Fish/squid	Year-round	Federally threatened
Dall's porpoise	*Phocoenoides dalli*	Common	Shelf/slope/ offshore	Fish	Year-round	
Harbor porpoise	*Phocoena phocoena*	Common	Shelf	Fish/squid	Year-round	State Candidate Species
Pacific white-sided dolphin	*Lagenorhynchus obliquidens*	Common	Slope/ offshore	Fish	Year-round	
Northern right whale dolphin	*Lissodelphis borealis*	Common	Slope/ offshore	Fish/squid	Year-round	
Common dolphin	*Delphinus delphis*	Rare	Offshore	Squid/fish	Unknown	
Striped dolphin	*Stenella coeruleoalba*	Rare	Shelf/offshore	Fish/squid/ zooplankton	Unknown	
Risso's dolphin	*Grampus griseus*	Common	Slope	Squid	Year-round	
Killer whale[1]	*Orcinus orca*	Common	Shelf/slope	Fish/marine mammals	Year-round	Federally/state endangered[1]
False killer whale	*Pseudorca crassidens*	Rare	Offshore	Fish	Unknown	
Pilot whale	*Globicephala macrorhynchus*	Rare	Shelf/offshore	Fish/ octopus	Unknown	
Pygmy sperm whale	*Kogia breviceps*	Rare	Offshore	Octopus/ fish/squid	Unknown	

Species	*Scientific Name*	Occurrence	Primary Habitat	Primary Prey	Season(s) Present	Federal/ State Status
Gray whale[2]	*Eschrichtius robustus*	Common	Coastal/shelf	Crustaceans	Year-round	State sensitive; ENP = Federally delisted; WNP = Federally endangered[2]
Humpback whale[3]	*Megaptera novaeangliae*	Common	Shelf/slope	Zooplankton/ fish	Spring to fall	State Endangered, Central America DPS= Federally endangered, Mexico DPS= Federally threatened, Hawaii DPS = Federally delisted[3]
Sperm whale	*Physeter macrocephalus*	Common	Slope/ offshore	Squid/fish	Spring to fall	Federally/state endangered
Minke whale	*Balaenoptera acutorostrata*	Uncommon	Shelf	Fish/squid	Year-round	
Fin whale	*Balaenoptera physalus*	Uncommon	Slope/ offshore	Fish/ zooplankton	At least winter	Federally/state endangered
Blue whale	*Balaenoptera musculus*	Rare	Slope/ offshore	Zooplankton	Unknown	Federally/state endangered
Sei whales	*Balaenoptera borealis*	Rare	Offshore	Zooplankton	Unknown	Federally/state endangered
Right whale	*Balaena glacialis*	Rare	Shelf	Zooplankton	At least spring	Federally/state endangered
Baird's beaked whale	*Berardius bairdii*	Rare	Shelf/offshore	Squid/ octopus/fish	At least fall	
Cuvier's beaked whale	*Ziphius cavirostris*	Rare	Offshore	Squid/fish	Unknown	
Stejneger's beaked whale	*Mesoplodon stejnegeri*	Rare	Offshore	Squid/fish	Unknown	
Sea otter (Washington stock)	*Enhydra lutris kenyoni*	Common	Coastal	Invertebrates	Year-round	State threatened

[1] NMFS has listed the Southern Resident killer whale population as endangered. Transient and offshore killer whales are not listed under ESA, but occur in the action area.

[2] The ENP stock of gray whales – the subject of the Makah waiver request – was delisted in 1994. The WNP stock is currently listed as endangered under the ESA and depleted under the MMPA (refer to Subsections 3.4.3.2.4, WNP Status, Carrying Capacity, and Related Estimates and 3.4.3.3.4, ENP Status, Carrying Capacity, and Related Estimates).

[3] NMFS revised the ESA listing of humpback whales in 2016 based on a global status review that identified 14 distinct population segments. As a result, the Central America DPS was listed as endangered, the Mexico DPS was listed as threatened, and the Hawaii DPS was delisted (81 FR 62259).

Source: Haley 1986; Calambokidis et al. (2004b); Brueggeman et al. (1992); Green et al. (1993); Carretta et al. (2006); Anglis and Outlaw (2005); Young et al. 2023; Carretta et al. (2023).

3.5.3.1.1 ESA-listed Marine Mammal Species

Killer Whale

There are three ecotypes of killer whales in the North Pacific Ocean: resident, transient, and offshore whales (Bigg et al. 1990; Ford et al. 2000). Resident killer whales (Northern and Southern ecotypes) congregate in relatively large groups in coastal areas where they forage primarily on fish. Transient killer whales, whose range extends over a broader area, primarily hunt marine mammals (Krahn et al. 2004; Baird et al. 1992). Three transient killer whale stocks are recognized within the Pacific U.S. EEZ: 1) the Gulf of Alaska, Aleutian Islands, and Bering Sea transient stock, occurring primarily from Prince William Sound through the Aleutian Islands and Bering Sea; 2) the AT1 transient stock, occurring in Alaska from Prince William Sound through the Kenai Fjords; and 3) the West Coast transient stock, occurring from California through southeast Alaska (Young et al. 2023). The West Coast Transient stock has a minimum population estimate of 349 animals with a PBR of 3.5 animals (Young et al. 2023). Transient pods are usually smaller than resident pods, and they typically have different dorsal fin shapes and saddle patch pigmentation than resident pods. Little is known about offshore killer whales, but their groupings are large. They range from Mexico to Alaska and are presumed to feed primarily on fish (Ford et al. 2000; Krahn et al. 2002; Krahn et al.2004). All three ecotypes of killer whales, including Southern and Northern Residents, were seen each year during ship surveys and detected at acoustic monitoring sites off the outer coast of Washington from August 2004 through September 2008 (Oleson et al. 2009). Oleson et al. (2009) reported 6 sightings of 51 animals; all of the groups sighted had fewer than 15 animals. More recently, killer whales (Southern Residents and transients) were encountered off Washington State during small boat surveys conducted in the spring of 2011 and 2012 (Jeffries et al. 2012). They reported 2 sightings of 13 animals in 2011, and 3 sightings of 9 animals in 2012. Killer whales were widely distributed across different habitats; animals were sighted both close to and far from shore and in fairly shallow and deep water.

As summarized by Carretta et al. (2023), most sightings of the Eastern North Pacific Southern Resident stock of killer whales have occurred in the summer in inland waters of Washington and southern British Columbia. Pods belonging to this stock have, however, also been sighted in coastal waters off southern Vancouver Island and Washington, especially between Grays Harbor and the Columbia River (Ford et al. 2000; Hanson et al. 2013; Emmons et al. 2021). Although less is known about the whales' coastal habitat use, recent acoustic studies, satellite tagging, and opportunistic sightings suggest that Southern Residents spend almost all of their time within 34

km of shore in water shallower than 200 m (Hanson et al. 2017), from Cape Flattery, Washington, to Point Reyes, California (Hanson et al. 2013). Of the three pods that compose this stock, one (J) is commonly sighted in inshore waters in winter, while the other two (K and L) apparently spend more time offshore (Ford et al. 2000; Hanson et al. 2017). In 1993, the three pods composing this stock totaled 96 killer whales (Carretta et al. 2023). The population increased to 99 whales in 1995, then declined to 79 whales in 2001, and recently numbered 74 whales in 2021 (Ford et al. 2000; Carretta et al. 2023). The minimum population estimate for the eastern North Pacific Southern Resident stock of killer whales is 74 animals with a PBR of 0.13 whales per year (Carretta et al. 2023). The Southern Residents primarily feed on salmon returning to rivers in Washington and southern British Columbia.

NMFS listed the Southern Resident killer whale distinct population segment as endangered in 2005 (70 FR 69903, November 18, 2005). Listing factors included reduced quantity and quality of prey, persistent pollutants that could cause immune or reproductive system dysfunction, oil spills, and noise and disturbance from vessel traffic. Additionally, the small size of this stock makes it potentially vulnerable to inbreeding that could cause a major population decline (70 FR 69903, November 18, 2005). In November 2006, NMFS designated critical habitat for the Southern Resident killer whales (71 FR 69054, November 29, 2006). This designation includes approximately 2,500 square miles (6,475 sq. km) of Puget Sound, including the entire Strait of Juan de Fuca in the action area. Areas with water less than 20 feet (6.1 m) deep are not included in the designation. NMFS revised the critical habitat designation for Southern Residents in 2021 to include 15,910 square miles (41,207 square km) of marine waters between the 20-foot (ft) (6.1-meter (m)) depth contour and the 656.2-ft (200-m) depth contour from the U.S. international border with Canada to Point Sur, California, excluding one area around the Quinault Range Site (86 FR 41668). The primary constituent elements for the Southern Resident killer whale critical habitat are 1) water quality to support growth and development; 2) prey species of sufficient quantity, quality, and availability to support individual growth, reproduction, and development, as well as overall population growth; and 3) passage conditions to allow for migration, resting, and foraging.

Humpback Whale

In 2015, NMFS completed a global status review of humpback whales (Bettridge et al. 2015) and, in 2016, revised the ESA listing to identify 14 DPSs (81 FR 62259, September 8, 2016). Of these, three are found in the Makah U&A: Central America (endangered), Mexico (threatened), and Hawaii (not listed). NMFS also evaluated the stock structure of humpback whales under the

MMPA and revised the stock definitions in the stock assessment reports (Carretta et al. 2023). There are two humpback whale stocks recognized in the North Pacific region stock assessment reports and one in the Alaska stock assessment reports that occur in the action area: (1) the Central America/Southern Mexico – California-Oregon-Washington (CA-OR-WA) stock, (2) the Mainland Mexico – CA-OR-WA stock, and (3) the Hawai'i stock.

Humpback whales filter-feed on small crustaceans (mostly krill) and small fish. Physical features facilitate formation of near-surface aggregations of humpback prey species (Tynan et al. 2005, Santora et al. 2011) and are, thus, likely to also influence humpback whale distributions (Bettridge et al. 2015). For example, extensive aerial surveys conducted off the coasts of Washington and Oregon from April 1989 to October 1990, indicated that the whales were particularly clustered along the southern edge of Heceta Bank off of Oregon and in the steeply sloped waters associated with submarine canyons off of Washington (Astoria, Grays, and Nitinat Canyons) (Green et al. 1992).

The primary wintering area for the Central America/Southern Mexico – CA-OR-WA stock includes the Pacific coasts of Nicaragua, Hondursa, El Salvador, Guatemala, Panama, Coasta Rica, Michoacán, and Colima. Individuals from this stock are primarily found in California and Oregon in the summer season, with only a few sightings in the Washington/southern British Columbia feeding areas (Carretta et al. 2023). Curtis et al. (2022) estimate the size of this population at 1,496 (CV=0.171) with a minimum abundance estimate of 1,284 whales using photographic capture-recapture methods between 2019 and 2021. This is almost double the 2004-2006 estimate that excludes whales from southern Mexico (Wade 2021). The PBR for this stock is estimated to be 5.2 whales per year (Carretta et al. 2023).

Mainland Mexico – CA-OR-WA stock humpback whales winter in Nayarit, Jaliso, Colima, and Michoacán, while their main summering areas include U.S. and Canadian West Coast waters from Calfornia to Alaska. This is the humpback whale stock that most commonly occurs in the action are during the summer (Wade 2021). Curtis et al. (2022) estimate the abundance of the Mainland Mexico – CA-OR-WA as the difference between the number of whales wintering in southern Mexico and Central America (i.e. the whales that make up the Central America/Southern Mexico – CA-OR-WA stock) and a recent estimate of total abundance of humpback whales in the U.S. West Coast EEZ from mark-recapture data (Calambokidis and Balrow 2020). This yields an abundance estimate of 3,477 anmals (CV=1.01). This may be an underestimate, as Calambokidis and Barlow (2020) did not include photographs of humpback whales off the coast of Washington, however there is movement of these whales between

Washington, Oregon, and California. Therefore, the estimate likely does include those individuals (Carretta et al. 2023). The minimum population estimate for this stock is 3,185 whales, with a PBR of 65 whales per year (Carretta et al. 2023).

The Hawai'i stock is composed of the combination of the Hawai'i – Southeast Alaska/Northern British Columbia DIP and the Hawai'i—North Pacific unit (Young et al. 2023). Whales in the Hawai'i – Southeast Alaska/Northern British Columbia DIP winer off Hawai'i and summer in Southeast Alaska and Northern British Columbia (Wade et al. 2021). There are a small number of individuals that migrate between Hawai'i and Southern British Columbia/Washington, but it is unlcear which unit within the stock these whales belong to (Wade 2021). The best current estimate of abundance for this stock is 11,278 (CV=0.56) with a minimum abundance estimate of 7,265 whales and a PBR of 127 whale per year (Young et al. 2023).

Members of the threatened Mexico DPS are also found in the Mainland Mexico – CA-OR-WA and Hawai'i stocks. The Mexico DPS breeds along the Pacific coast of Mexico and the Revillagigedo Islands; it feeds across a broad range from California to the Aleutian Islands (81 FR 62259, September 8, 2016). The Mexico DPS has been estimated to have an abundance of about 2,913 whales based on data collected in 2004-2006 (CV= 0.066, Wade 2021).

The Southern Mexico- CA-OR-WA stock includes whales from Central America DPS. This population breeds along the Pacific coast of Central America; the population feeds off the west coast of the United States and southern British Columbia (81 FR 62259, September 8, 2016). It is estimated that most Central America DPS whales use California-Oregon waters for feeding (NOAA 2016; Wade et al. 2016; Wade 2021). In terms of distribution across their foraging range, these whales are significantly more common in waters of southern California and occur in increasingly lower numbers off the coast of Washington and Southern British Columbia (Steiger et al. 1991; Calambokidis et al. 2000, 2008, 2017). This distribution pattern was also confirmed by the results of the SPLASH study, which indicated that out of 29 between-season photo-identification matches of whales from the Central America breeding areas, 26 occurred within the California/ Oregon feeding area and 3 occurred within the northern Washington/ southern British Columbia area (Barlow et al. 2011). Bettridge et al. (2015) note that use of the Salish Sea by this DPS may be extremely limited and has been indicated by the single re-sighting reported in Calambokidis et al. (2017). The Central America DPS has been most recently estimated to include about 755 whales based on data collected in 2004-2006 (CV = 0.242) (Wade 2021).

Humpbacks are generally seen off the coast of Washington from May to November, although they have also been seen earlier in the spring and later in the winter (Shelden et al. 2000) with the

highest numbers in June and July. A recent survey conducted along the west coasts of Vancouver Island, the United States, and northern Mexico from June through November of 2018 recorded 179 sightings of 578 animals off the coast of Washington (Henry et al. 2020). Calambokidis et al. (2004b) reported sightings of humpback whales during ship surveys conducted from 1995 to 2002 off the northern Washington coast within the boundaries of the OCNMS. Humpbacks were the most common species seen, with 232 sightings of 402 animals and more than 191 unique individuals; the largest numbers were seen in 2002 when there were 79 sightings of 139 individuals. Group sizes ranged from one to eight animals. Only six calves were recorded from the ship surveys, probably because it was difficult to identify calves at the distance at which most sightings occurred. Sightings were concentrated between Juan de Fuca Canyon and the outer edge of the continental shelf, an area called the Prairie. A small area east of the mouth of Barkley Canyon and north of Nitnat Canyon where the water was approximately 410 to 475 feet (125 to 145 m) deep had numerous sightings in all years. Smaller numbers of humpback whales were also seen on Swiftsure Bank. Wade (2021) used a mark recapture model as well as photo-identification data to estimate abundance within the winter and summer areas of the North Pacific sampled in the 2004-2006 SPLASH project, as well as estimate migration rates between these areas. NMFS used these results to estimate mixing ratios of the three DPSs present in Washington coastal waters. The relative probability that an encountered humpback on the Washington coast would be from the non-listed Hawaii DPS, threatened Mexico DPS, or endangered Central America DPS is 69 percent, 25 percent, and 6 percent, respectively (NMFS 2021a).

Sperm Whale

The sperm whale is listed as endangered throughout its range (35 FR 8491, June 2, 1970). Sperm whales are widely distributed in the pelagic regions of the North Pacific Ocean where they prey on deepwater squid (Gosho et al. 1984). Sperm whales breed in the lower latitudes (south of 40° N) in winter and then migrate northward to summer feeding areas. Whaling records indicate that about eight sperm whales were harvested annually by whalers at the Bay City, Washington whaling station during its 15 years of operation in the early 1900s, suggesting that sperm whales were regularly present off the coast at that time. Ship surveys by Jeffries et al. (2012) from 2011 and 2012, Oleson et al. (2009) from 2004 to 2008, and Calambokidis et al. (2004b) from 1995 to 2002 recorded no sperm whales. However, sperm whales were heard in all months of the year from 2004 to 2008 at the offshore acoustic monitoring station off the outer Washington coast (Oleson et al. 2009). In surveys Brueggeman et al. (1992) conducted, 24 groups of 36 sperm whales were recorded off the Oregon and Washington coasts. Most were encountered in the

deeper offshore waters except for a relatively small number found in continental slope waters. Brueggeman et al. (1992) observed sperm whales during spring through fall, but not in winter. The highest single-day count was 13 sperm whales in September 1990. Green et al. (1993) reported seven sperm whales in five groups off the Oregon and Washington coasts between March and May. The most recent estimate of abundance for the California/Oregon/Washington stock is 1,997 sperm whales; the minimum population estimate is 1,270 animals with a PBR of 2.5 whales per year (Carretta et al. 2023). The population abundance for the California/Oregon/Washington stock appears to have been rather variable and does not show any obvious trends. The information indicates that relatively small numbers of sperm whales are present in the deep waters off the Washington coast from spring through fall.

Fin Whale

The fin whale is listed as endangered throughout its range (35 FR 8491, June 2, 1970). Three stocks are generally recognized off the United States west coast: the California/Oregon/Washington stock, the Hawaii stock, and the Northeast Pacific stock (Carretta et al. 2023). Fin whales of the California/Oregon/Washington stock are year-round residents off the coast of California; they summer off the Oregon coast and may pass by the Washington coast. They are a pelagic species, seldom found in waters shallower than 656 feet (200 m). During 2011 and 2012 ship surveys off the Washington and Oregon coasts, Jeffries et al. (2012) reported seven sightings of 13 animals. From 2004 to 2008, Oleson et al. (2009) reported one sighting of two animals along the outer Washington coast during ship surveys. Ship surveys by Calambokidis et al. (2004b) from 1995 to 2002 indicated no fin whales. Aerial surveys Brueggeman et al. (1992) conducted off the Oregon and Washington coasts indicated 13 groups of 27 fin whales between June and January. All of the fin whales were observed off the Oregon coast, with all but five whales in waters on the continental slope (656 to 6,562 feet [200 to 2,000 m] deep). The whales that were not observed in continental slope waters included two seen about 124 miles offshore in November and three viewed on the continental shelf just south of the Columbia River in January. The former group was traveling south, suggesting they were migrating back to the wintering grounds. Except for these two groups of whales, all the other whales were observed during June and July. No calves were observed with any of the whales. Green et al. (1993) reported sighting two fin whales during aerial surveys off the coast of Oregon and Washington between March and May in 1992, but did not report the location. An estimated 3,044 fin whales occur off the coasts of California, Oregon, and Washington during summer and fall, based on shipboard surveys in 2005 by Forney (2007) and in 2008 by Barlow (2010). A best-estimate of abundance of 11,065

animals was derived from a species distribution model using 1991-2018 line-transect survey data. The minimum population estimate from the 2018 estimate is 7,970 whales with a PBR of 80 whales per year (Carretta et al. 2023).Fin whales can be distinguished from other mysticetes (baleen whales, such as gray, humpback, sei, bowhead, and fin whales) by distinct coloration on the head. The pigmentation differs on the left side and right side, as well as on the dorsal and ventral surface. On the left side, both the dorsal and ventral surfaces are dark slate. On the right side, the dorsal surface is gray and the ventral surface is white (Aguilar 2002). Fin whales in the northern hemisphere typically feed on small schooling fish, planktonic crustaceans, small squid, and zooplankton (Aguilar 2002; Nowak 2003).

Blue Whale

Blue whales are the largest animal, with recorded lengths of 104 to 107 feet (31.7 to 32.6 m). Females are typically larger than males, and southern hemisphere whales are larger than those of the northern hemisphere (the largest recorded was 92 feet [28 m]) (Sears 2002). The species is listed as endangered under the ESA (35 FR 8491, June 2, 1970) throughout its range. Three stocks of blue whales inhabit United States waters: the western North Atlantic stock, the central North Pacific stock (formerly called the Hawaiian stock), and the eastern North Pacific stock. The eastern North Pacific stock feeds in California waters in summer and fall (from June to November) and migrates south to productive areas off Mexico and as far south as the Costa Rica Dome in winter and spring (Carretta et al. 2023). Blue whales are very rarely seen off the Oregon coast, but there have been sightings off the Washington coast (Calambokidis and Barlow 2004; Calambokidis et al. 2004b; Calambokidis et al. 2009b; Cascadia Research Collective 2011; Carretta et al. 2023). Blue whales are found in coastal and deep offshore waters but also occur on the continental shelf. Blue whales appear to feed almost exclusively on krill (which are relatively large euphausiid crustaceans) worldwide in areas of cold current upwelling (Nowak 2003; Sears 2002). Some other prey species, including fish and copepods, have been reported as being consumed by blue whales, but these prey are unlikely to contribute substantially to the diet of blue whales (NMFS 2015c). The best estimate of the eastern North Pacific blue whale stock is 1,898 individuals with a minimum population estimate of 1,767 with a PBR of 4.1 whales per year (Carretta et al. 2023). There is some indication that blue whale increased in abundance in California coastal waters between 1991 and 1996 based on photographic mark-recapture data. Population abundance trends fluctuated between 1997 and 2013 but remained relatively stable before increasing in 2014 (Carretta et al. 2023). Blue whales would not be expected to occur in the action area.

Sei Whale

The sei whale is listed as endangered throughout its range under the ESA (35 FR 8491, June 2, 1970). Sei whales are rare off California, Oregon, and Washington (Carretta et al. 2023). Two sei whales were tagged off California in 1962 and 1965, and later commercially taken off the Washington coast in 1969 and British Columbia in 1966 (Rice 1974). No sei whales were observed during aerial surveys conducted by Brueggeman et al. (1992) off the coast of Oregon or Washington in 1991 or in 1992, during surveys by Green et al. (1993), or during ship surveys conducted by Jeffries et al. (2012) in 2011 and 2012, by Oleson et al. (2009) from 2004 to 2008, or by Calambokidis et al. (2004b) from 1995 to 2002. Sei whales are primarily found offshore in deeper water and are not associated with coastal waters. Sei whales primarily prey on copepods and amphipods, but also take euphausiids and small fish (Nowak 2003). The most recent abundance estimate for sei whales off California, Oregon, and Washington out to 300 nautical miles (556 km) from the coast is 519 whales based on the unweighted geometric mean of shipboard surveys in 2008 and 2014 (Barlow 2016; Carretta et al. 2023). The minimum population estimate is 374 whales with a PBR of 0.75 whales per year (Carretta et al. 2023). Sei whales are not expected in the action area.

Right Whale

The North Pacific right whale is listed as an endangered species under the ESA (35 FR 8491, June 2, 1970). It is the least abundant of all whale species. Right whales are found in three general regions: the North Atlantic, the North Pacific, and the Southern Hemisphere. The North Pacific stock has two populations: a Sea of Okhotsk stock and an eastern North Pacific stock. The range of the latter population is thought to include the west coast from Mexico to Alaska (Brownell et al. 2001; Clapham et al. 2004), although a few have been observed off the Washington coast. A group of eight right whales was reported off Destruction Island, Washington in April 1959 (Fiscus and Niggol 1965). One individual was photographed on October 25, 2013 off British Columbia and northern Washington State showing evidence of probable fishing gear entanglement (Ford et al. 2016). Recent extensive ship surveys in western Alaska indicated no sightings of right whales (Zerbini et al. 2006), nor were any seen off Washington during ship surveys from 1995 to 2012 (Calambokidis et al. 2004b; Oleson et al. 2009; Jeffries et al. 2012). Right whales generally feed on zooplankton, including copepods, near the coast and continental shelf edge. Reliable estimates of population size and trends are not known (Angliss and Outlaw 2005), but observers believe that the North Pacific stock numbers 100 to 200 animals, a small fraction of the pre-whaling abundance (Nowak 2003). More recently, Wade et al. (2011)

produced a best estimate of 31 right whales in the Bering Sea. The minimum estimate of abundance is 26 with a PBR of 0.05 (Young et al. 2023) based on the photo-identification estimate of 31 whales (Wade et al. 2011). This information suggests that a small number of right whales could occur off the Washington coast; however, the probability is extremely low (Carretta et al. 2006).

3.5.3.1.2 Common Species off the Washington Coast

Steller sea lions, harbor seals, California sea lions, northern fur seals, northern elephant seals, Dall's porpoises, harbor porpoises, Pacific white-sided dolphins, Risso's dolphins, northern right whale dolphins, and minke whales are common in the action area. A short description of each of these species is provided below.

Steller Sea Lion

The eastern stock (identified as a DPS) of Steller sea lions extends from California to 144° W longitude (at Cape Suckling, Alaska) at the northern end of southeast Alaska and includes Washington and Oregon. Based on extrapolations from pup counts, the stock is estimated to be within the range of 65,342 and 90,305 animals with a minimum population estimate of 43,201 and a PBR of 2,592 (Young et al. 2023). This stock was listed as threatened under the ESA in 1990 (55 FR 12645, April 5, 1990) but was delisted in 2013 (78 FR 66139, November 4, 2013). Overall, the non-pup portion of population has been increasing at about 3.22 percent per year from 1987 to 2017 (Young et al. 2023). The best available information indicates the eastern stock has increased from an estimated 18,040 animals in 1979 to an estimated 70,174 animals in 2010 (NMFS 2013c).

The Steller sea lion occurs year-round in Washington State (NMFS 1992b). Pupping in Washington has been increasing, and a new rookery has become established on the outer Washington coast just south of the action area at the Carroll Island and Sea Lion Rock complex in the last several years, where pupping occurs from late May to early July (Young et al. 2023). Within Washington, Steller sea lions occur primarily in the nearshore zone and continental shelf zone, with smaller numbers in the inside waters of the Strait of Juan de Fuca and Puget Sound.

There are several Steller sea lion haulout sites in the action area that are used in all months of the year (Gearin and Scordino 1995); peak counts of Steller sea lions in the action area are in spring and fall. Haulout sites within the action area include Tatoosh Island (48° 23.32' N, 124° 44.26' W), Guano Rock (48° 10.90' N, 124 44.52' W), East Bodelteh Island (48° 10.57' N, 124 45.15' W), and West Bodelteh Island (48° 10.75' N, 124 46.27' W) (Jefferies et al. 2000). Steller sea

lion counts are variable within and between years. During 2011 and 2012, the average count in the action area peaked in November at 842 sea lions and was the least in September at 79 sea lions (J. Scordino, Makah Tribe Marine Mammal Biologist, pers. comm., February 7, 2014).

Steller sea lions are opportunistic predators, feeding primarily on a wide variety of fish and cephalopods. Some of the more important prey species in Washington include Pacific whiting, Pacific herring, spiny dogfish, skates, salmon, and smelts (Gearin et al. 1999). Before 2005, Makah tribal regulations explicitly advised subsistence hunters to take care in hunting California sea lions to avoid Steller sea lions (Sepez 2001); since 2005, the Tribe has not authorized direct subsistence harvest of any marine mammals.

Harbor Seal

For management purposes, three harbor seal stocks are recognized along the west coast of the continental United States, including the California stock, outer coast of Oregon and Washington stock, and Washington inland waters stock (Carretta et al. 2023). Harbor seals from the last two stocks occur year-round within the action area. Both occur principally in the nearshore zone and are the most common marine mammal in Washington (NMFS 1992b). In 1999, mean counts from aerial surveys showed 10,430 seals off the Washington coast and 5,735 in Oregon, totaling 16,165 harbor seals for the outer coast of Oregon and Washington stock, or a population estimate of 24,732 after using a correction factor to account for seals in the water that are missed during aerial surveys (Jeffries et al. 2003). The mean number of seals in the Washington inland waters stock was estimated to be 14,612 in 1999 (Jeffries et al. 2003); more recent estimates are not available (Carretta et al. 2023). Because the most recent abundance estimates for both of these stocks are greater than 8 years old, there are no current estimates of abundance, minimum population estimates, or PBRs available for these stocks.

Harbor seals give birth on shore and nurse their pups for 4 to 5 weeks. After the pups are weaned, they disperse widely in search of food. Pupping along the outer coast of Washington and the Strait of Juan de Fuca occurs in May through July, and additionally in August in the strait. Breeding occurs in the water shortly after the pups are weaned. The Makah U&A contains 32 harbor seal haulout sites (Gearin and Scordino 1995; Jefferies et al. 2000). This area (the Makah U&A) is subdivided for convenience into three areas (western Strait of Juan de Fuca complex, Cape Flattery Complex, and the Cape Alava Complex) with variable harbor seal densities within each complex. The western Strait of Juan de Fuca complex has the lowest density (number of seals per nautical mile); the Cape Alava area has the highest density and number of pups (Gearin and Scordino 1995; Jefferies et al. 2000). Common prey include sole, flounder, sculpin, hake, cod, herring, squid, octopus, and, to a lesser degree, salmon (Jeffries and Newby 1986; Orr et al. 2004). California Sea Lion

The California sea lion includes three subspecies of which *Zalophus californianus californianus* (found from southern Mexico to southwestern Canada) occurs in the action area. California sea lions breed on islands in three geographic regions that are used to separate this subspecies into five stocks: the United States stock, which begins at the United States/Mexico border and extends northward into Canada; the Western Baja California stock, which extends from the United States/Mexico border to the southern tip of the Baja California Peninsula; and the Gulf of California stocks (Southern Gulf of California, Central Gulf of California, and Northern Gulf of California) that include the Gulf of California from the southern tip of the Baja California peninsula (Carretta et al. 2023). Based on extrapolations from pup counts, the population is estimated to be 257,606 sea lions (Carretta et al. 2023). The minimum population estimate is 233,515 sea lions with a PBR of 14,011 per year (Carretta et al. 2023).

Males migrate northward along the coast following the summer breeding season in California (the species' only known breeding area). Beginning in August, male California sea lions appear along the outer Washington coast principally in the nearshore and continental shelf zones. Some move into Puget Sound and British Columbia. California sea lions remain in Washington waters through the winter and early spring before returning to California in May and June (Gearin and Scordino 1995; Jeffries et al. 2000). The migration can be characterized as a feeding migration consisting primarily of adult and sub-adult males. California sea lion females and younger animals less than 4 to 5 years old tend to remain near the home rookeries throughout the year, or move only as far north as central California. California sea lions are common in the action area during fall, winter, and spring. In the action area, California sea lions haul out within the Neah Bay Harbor, at Waadah Island (48° 23.19' N, 124° 36.02' W), Tatoosh Island, East Bodelteh, and West Bodelteh, as well as on mooring buoys (Jefferies et al. 2000). As many as 4,000 to 5,000 California sea lions have been observed on the Bodelteh Islands during the fall. Farther south on Carroll Island, 200 to 300 sea lions may haul out during the migration peak. Little is known of their diet on the Washington coast, but preliminary data collected by the Makah Tribe at Washington haulouts show that they feed primarily on Pacific whiting, Pacific herring, American shad, salmonids, dogfish sharks, Pacific sardine, northern anchovy, and rockfish (J. Scordino, Makah Tribe Marine Mammal Biologist, pers. comm., March 21, 2013). Before 2005, the Makah Tribe promulgated regulations allowing Tribe members to exercise treaty rights for subsistence harvest of sea lions. Up to two sea lions were taken for subsistence each year (Carretta et al. 2006).

Northern Elephant Seal

Northern elephant seals, estimated to number 187,386 animals, breed off Mexico and California during winter and move northward in the spring to feed from Baja California to northern Vancouver Island and far offshore of the Gulf of Alaska and Aleutian Islands (Nowak 2003; Carretta et al. 2023). The minimum population estimate is 85,369 seals with a PBR of 5,122 per year (Carretta et al. 2023). Populations of northern elephant seals in the United States and Mexico all originally derived from a few tens or a few hundreds of individuals surviving in Mexico after they were nearly hunted to extinction. The California breeding population is now demographically isolated from the Baja California population and is considered a separate stock for management purposes (Carretta et al. 2023). The majority of elephant seal sightings occurred from January to June during visual surveys off the coast of Washington from 2004 to 2008 (Oleson et al. 2009). In contrast, Brueggeman et al. (1992) found that elephant seals occurred off the Washington coast primarily during summer and early fall. They were the second most common pinniped sighted during summer ship surveys off the Washington coast from 1995 to 2002 (Calambokidis et al. 2004b). In contrast, all the elephant seals Brueggeman et al. (1992) observed from mid-fall through spring were off the Oregon coast. Most of the elephant seals they encountered were over the continental shelf and slope, at a mean distance of almost 40 miles (64.4 km) from the coast. Small numbers of elephant seals haul out on East Bodelteh Island during the molting season and rarely at Tatoosh Island (J. Scordino, Makah Tribe Marine Mammal Biologist, pers. comm., March 21, 2013). Elephant seals prey on deepwater and bottom dwelling organisms, including fish, squid, crab, and octopus (Nowak 2003).

Northern Fur Seal

The eastern Pacific stock of the northern fur seal is estimated to number 611,617 animals; the minimum population estimate is 626,618 with a PBR of 11,403 (Young et al. 2023). Based on significant declines in abundance during the 1960s and 1970s, the Pribilof Islands population was listed as depleted under the MMPA in 1984 because population levels had declined to levels lower than 50 percent of those observed in the 1950s (1.8 million animals) (53 FR 17888, May 18, 1988) . Causes of decline and current threats are uncertain but may include climate change, vessel and human presence, depletion of prey species, predation, and environmental contamination (NMFS 2007).

Fur seals are a seasonal migrant off the Washington coast, and they do not breed or haul out (although individuals may infrequently be seen on land intermixed with sea lions) in Washington (Angliss and Outlaw 2005). The closest rookeries are in the Bering Sea (Pribilof Islands and Bogoslof Island) and the Channel Islands (San Miguel Island) off the California coast. During the

July to August breeding season, most of the population is found on the Pribilof Islands. Females and juveniles of both sexes migrate south in fall into waters over the continental shelf and slope of the eastern North Pacific Ocean, while adult males generally stay in Alaska waters (Gentry 2002). The migration ranges as far south as 30 to 32° N latitude off southern California and northern Baja, Mexico. Fur seals begin the return migration northward in mid-spring; by early summer, most have returned to their breeding islands (Gentry 2002; Nowak 2003).

In Washington, Oleson et al. (2009) and Brueggeman et al. (1992) reported that northern fur seals primarily inhabited the deep offshore waters, but they also used the continental shelf and slope waters. They were observed off the Washington coast year-round, but most individuals (more than 90 percent) were encountered from January through May. Sightings of northern fur seals in the Strait of Juan de Fuca or Puget Sound are rare, but they do occur occasionally (Gearin and Scordino 1995). They feed on walleye pollock, Pacific herring, capelin, squid, and small schooling fishes (Kajimura 1984). Pribilof Islands Aleut Natives take approximately 600 to 800 sub-adult male fur seals per year for subsistence use (Angliss and Outlaw 2005). Makah Tribe hunters took fur seals from canoes in the open ocean in the late 1800s and into the 1900s, but they do not currently hunt them nor have they recently been taken incidental to the Makah set net fisheries (Swan 1883; Swan 1887; Sepez 2001).

Northern Sea Otter

Sea otters occurred historically along the outer coast of Washington; the population was severely over-hunted in the late mid-1700s to 1800s and extirpated in the Pacific Northwest by 1920 (NMFS 1992b; Jameson 1995). The last known native sea otters in Washington were taken in Willapa Bay in 1910 (Scheffer 1940). In 1969 and 1970, 59 northern sea otters were transplanted to Washington from Amchitka Island, Alaska (Lance et al. 2004). Although the otters off Washington State are descended from the Amchitka Island sea otters and are, thus, related to the southwest Alaska distinct population segment listed as threatened under the ESA (70 FR 46366, August 9, 2005), they are geographically isolated from the southwest Alaska population by hundreds of miles and are not included in the listing. Sea otters off the Washington coast have been listed as a Washington State endangered species since 1981 because of their small population size, restricted distribution, and vulnerability (Lance et al. 2004).

The USFWS has conducted cooperative sea otter surveys with WDFW since 1985. Between 1989 and 2016, the sea otter population increased at a 9 percent annual rate with a population of 1,380 sea otters in 2016 (Jeffries et al. 2016). The PBR for this stock is 18 animals (USFWS 2018). Laidre et al. (2011) estimated the carrying capacity of sea otters at 1,854 individuals (95 percent

confidence interval from 1,499 to 2,208), based on an assumption that sea otters will reoccupy most of their historic habitat along the outer Washington coast (excluding reoccupation of the Columbia River, Willapa Bay, and Grays Harbor estuaries because of significant human alterations and use) and eastward into the Strait of Juan de Fuca as far as Protection Island. The 2016 estimated population abundance is very close to the carrying capacity estimate reported by Laidre et al. (2011). However, the sustained annual growth rate of 9 percent does not indicate that the population is approaching carrying capacity, suggesting that the estimate may not be a good representation of current habitat capabilities. In fact, more recent estimates of carrying capacity incorporating more data from the last decade are higher than that predicted by Laidre et al. (2011) (Hale et al. 2022). In the absence of a reliable carring capacity estimate, the stock's status relative to OSP cannot be determined (USFWS 2018).

The current sea otter population range extends around the Olympic Peninsula from as far south as Cape Elizabeth on the outer Olympic Peninsula coast to as far east as Pillar Point in the Strait of Juan de Fuca, with concentrations near Duk Point, Cape Alava, Sand Point, Cape Johnson, Perkins Reef, and Destruction Island (Figure 3-2). However, scattered individuals have been seen outside of this range (USFWS 2018). More than half of the population occurs outside of the Makah U&A south of La Push, with the single largest concentration of otters located at Destruction Island (Jameson and Jeffries 2005; Jameson and Jeffries 2013). A large group of males moved into the Strait of Juan de Fuca during winter in the 1990s (Lance et al. 2004) but have not done so since 2000. In 2011, only two sea otters were observed in the Strait of Juan de Fuca during the annual surveys, both east of Waadah Island near Neah Bay (Jameson and Jeffries 2013). Sea otters generally inhabit shallow coastal waters less than 1 mile from shore, but sea otters are found out to at least 5 miles from the Cape Alava area. In Washington, sea otters generally stay in relatively shallow waters and forage on a variety of marine invertebrates, including sea urchins, throughout their entire depth range from intertidal areas out to at least 20 fathoms (120 feet/36.6 m) (Lance et al. 2004). Sea otters pup in late winter and early spring, and the pups are weaned in late summer and early fall. Reproduction occurs throughout the area (Lance et al. 2004). Post-weaning mortality is higher for males than females and increases as resources become limited (Estes and Bodkin 2002). Low levels of mortality occur in adult females as a result of injury by males during copulation (Estes and Bodkin 2002). Sea otters are preyed upon by white sharks, killer whales, and, infrequently, Steller sea lions. Of the marine mammals within the action area, they (and northern fur seals) are most susceptible to mortality caused by oil spills because of damage to their fur, which is important in regulating metabolism (Ballachey et al. 1994).

Harbor Porpoise

Two harbor porpoise stocks are recognized within the action area, the Washington Inland Waters stock and the Northern Oregon/Washington Coast stock. Some movement between the two stocks is likely, but is currently not possible to quantify (Carretta et al. 2023). The most recent estimate of abundance for the Washington Inland Waters stock is from 2013 to 2015 and is 11,233; the minimum population estimate is 8,308 animals with a PBR of 66 (Carretta et al. 2023). The Northern Oregon/Washington Coast stock was estimated to number 21,487 animals in 2010-2011; the minimum population estimate is 15,123 individuals with a PBR of 151 (Carretta et al. 2023). The Northern Oregon/Washington Coast stock is present year-round off the Washington coast, and those in the Inland Waters stock are present throughout most of the year in inland waters (Carretta et al. 2023). Numbers of harbor porpoises are particularly high in the fall and winter, low in the summer, and intermediate in the spring (Brueggeman et al. 1992). Oleson et al. (2009) reported 114 sightings of 244 animals during boat surveys off the coast of Washington between 2004 and 2008. The fall sightings were closest to shore, farthest from the shelf edge, and in shallower waters. However, in the summer, sightings were farthest from shore, closest to the shelf edge, but in deeper water. They are widespread throughout the inland and coastal waters of Washington with the exception of southern Puget Sound (NMFS 1992b). Scheffer and Slipp (1948) provide a historical account of this species in Washington.

Harbor porpoises are known to calve and breed in Washington, and they generally give birth in summer from May through July. Calves remain dependent for at least 6 months (Leatherwood et al. 1982). Harbor porpoises are usually shy and avoid vessels; thus, they are difficult to approach. The species frequents inshore areas, shallow bays, estuaries, and harbors. Harbor porpoises are found almost exclusively shoreward of the 100-fathom (600-foot/183-m) contour line along the Pacific coast, with the vast majority found inside the 25-fathom (150-foot/46-m) curve (Gearin and Scordino 1995; Green et al. 1992). The primary prey of harbor porpoise are small fish and squid typically found in shallow waters. Bottom-dwelling fishes and small pelagic schooling fishes with high lipid content, including herring and anchovy, are common prey (Bjorge and Tolley 2002; Leatherwood and Reeves 1986). Small numbers of harbor porpoise have been taken incidentally in Makah set net fisheries, including two individuals in 2004 but none from 2005 through 2009 (Carretta et al. 2013).

Dall's Porpoise

Dall's porpoises are common off the Washington coast, but their distribution and abundance are variable and likely linked to oceanographic conditions (Carretta et al. 2023). They are probably

the most widely distributed cetacean in the temperate and subarctic regions of the North Pacific and Bering Sea (Leatherwood et al. 1982). An estimated 16,498 Dall's porpoises occur in the California, Oregon, and Washington stock with a minimum population estimate of 10,286 and a PBR of 99 animals per year (Carretta et al. 2023). Jeffries et al. (2012) reported 69 sightings of 244 individuals during boat surveys off the Washington and Oregon coasts between 2011 and 2012. During ship surveys off the Washington coast between 2004 and 2008, Oleson et al. (2009) reported 44 sightings of 206 animals. They were the most common small cetacean observed in ship surveys off the Washington coast from 1995 to 2002 with 115 sightings of 406 animals (Calambokidis et al. 2004b). Brueggeman et al. (1992) reported 152 groups containing 341 Dall's porpoise, including four calves, during surveys off the coast of Oregon and Washington. Porpoises were most common during fall, least common during winter, and intermediate in occurrence during spring and summer, although encounter rates were not substantially different among seasons, suggesting that a resident population occurs off the coast of Oregon and Washington (Brueggeman et al. 1992). Encounter rates were highest over the continental slope, lowest on the continental shelf, and intermediate in offshore waters. They rarely occurred in shallow coastal waters. Dall's porpoises were observed in small groups, which are consistent with observations reported in other studies, although aggregations of at least 200 individuals have been reported. They occur only rarely in groups of mixed species, although they are sometimes seen in the company of harbor porpoises and gray whales (Klinowska 1991; Reeves and Leatherwood 1994; Oleson et al. 2009). Dall's porpoises apparently feed at night. They depend, to some degree, on the deep scattering ocean layer through which fauna travel upwards each night from the deeper parts of the water column. Prey species, as determined from stomach contents, include squid and schooling fishes (Jefferson 2002; Klinowska 1991; Reeves and Leatherwood 1994). Killer whales and sharks are believed to be the primary natural predators of Dall's porpoises.

Pacific White-Sided Dolphin

The Pacific white-sided dolphin numbers an estimated 34,999 animals in the California, Oregon, and Washington stock, and it is one of the most abundant dolphins occurring year round off the coast of Washington (Brueggeman et al. 1992; Green et al. 1993; Carretta et al. 2023). The estimated minimum population level is 29,090 with a PBR at 279 dolphins per year (Carretta et al. 2023). Jeffries et al. (2012) reported four sightings of 159 animals in 2011 and six sightings of 171 animals in 2012 off the coasts of Washington and Oregon. Between 2004 and 2008, white-sided dolphins were acoustically detected 9 to 10 months each year in the coastal waters of Washington; nighttime detection rates were eight times higher than daytime detection rates

(Oleson et al. 2009). Oleson et al. (2009) also recorded 18 sightings of 1,681 animals during visual surveys along the outer Washington coast. Calambokidis et al. (2004b) recorded 28 sightings of 1,133 individuals in offshore waters during ship surveys off the Washington coast from 1995 to 2002. Some seasonal shifts occur off the coast of Oregon and Washington where dolphins are more common in offshore waters during spring. Their distribution shifts to continental slope waters during summer and fall, in rough synchrony with the movements of prey (VanWaerebeek 2002). Pacific white-sided dolphins may also move north to south seasonally (Forney and Barlow 1998). Although peak abundances off the Oregon and Washington coast have been reported during May from visual surveys (Brueggeman et al. 1992; Buckland et al. 1993), acoustic detections peaked in the summer and high levels of detection continued through November (Oleson et al. 2009). Pacific white-sided dolphins consume a wide variety of fishes and cephalopods. Off the coast of British Columbia, herring was the most commonly occurring prey species, followed by salmon, cod, shrimp, and capelin (Heise 1997). Pacific white-sided dolphins have been known to occur in association with other marine mammals, including Dall's porpoise, Risso's dolphin, northern right whale dolphin, humpback whale, and gray whale (Brueggeman et al. 1992).

Risso's Dolphin

Risso's dolphins are distributed world-wide in warm-temperate and tropical waters along the continental shelf and slope edge. They are estimated to number 6,336 animals in the California, Oregon, and Washington area with a minimum population level of 4,817 a PBR of 46 per year (Carretta et al. 2023). Risso's dolphins are common off the coast of Washington, where they are present year-round (Brueggeman et al. 1992). Jeffries et al. (2012) reported two sightings of six animals in the coastal waters off Washington in the summer of 2011, while Henry et al. (2020) reported more than eight sightings of Risso's dolphins off the coast of Washington and Vancouver Island in the summer of 2018. During surveys along the outer coast of Washington between 2004 and 2008, Risso's dolphins were acoustically detected an average of 5 to 6 days per year but were only visually observed on two occasions with 38 animals documented (Oleson et al. 2009). Nine sightings of 79 individuals were reported off the Washington coast during ship surveys from 1995 to 2002 (Calambokidis et al. 2004b). They are most common during spring and summer, least common in winter, and intermediate in occurrence during the fall (Brueggeman et al. 1992). Calves have been observed off the coast of Oregon and Washington during May, July, and November. Risso's dolphins primarily inhabit continental slope waters, but they also occur in lower numbers near the edge of the continental shelf. Risso's dolphins are

consistently found on the continental slope and in shelf-edge waters throughout the year, suggesting there is no inshore to offshore movement pattern. However, there may be some seasonal north to south movement of Risso's dolphins between Oregon/Washington and California, based on the shifts in abundance between the two regions, possibly related to prey movements. Principal prey include cephalopods and fish, and limited behavioral research suggests that they feed primarily at night (Baird 2002; Nowak 2003). Risso's dolphins have been known to occur in association with other marine mammals, including Pacific white-sided and northern right whale dolphins (Brueggeman et al. 1992). No habitat issues are known to be of concern for this species, and human-caused mortality from commercial fishing and other sources is low (Carretta et al. 2023).

Northern Right-Whale Dolphin

The California, Oregon, and Washington stock of the northern right-whale dolphin is estimated at 29,285 animals with a minimum population estimate of 17,024 and a PBR of 153 dolphins per year (Carretta et al. 2023). The species is relatively common off the coast of Washington, which is toward the northern end of its range in the eastern North Pacific Ocean (Brueggeman et al. 1992). Oleson et al. (2009) reported three sightings of 59 animals during ship surveys off the Washington coast from 2004 to 2008. Henry et al. (2020) reported nine sightings off the coast of Washington and Vancouver Island in the summer of 2018. The northern right-whale dolphin has been reported in Washington waters during all seasons except winter (Calambokidis et al. 2004b; Brueggeman et al. 1992). Numbers are highest in the fall and lowest during spring and summer. While northern right whale dolphins show a seasonal abundance pattern off the Washington coast that is somewhat opposite of the California pattern, it is not clear whether they move between the two areas. They are gregarious animals, often traveling in groups of 2,000 to 3,000 animals. The primary prey for this species include lanternfish, Pacific whiting, saury, mesopelagic fish, and squid (Lipsky 2002). The northern right-whale dolphin has been frequently reported in association with Pacific white-sided dolphins (Leatherwood and Walker 1979; Brueggeman et al. 1992).

Minke Whale

Minke whales in the north Pacific are believed to be migratory, but those in the inland waters of Washington and in central California appear to establish home ranges (Dorsey et al. 1990). These "resident" minke whales in coastal waters of California, Oregon, and Washington (including Puget Sound) appear behaviorally distinct from migratory whales furhter north, and are therefore considered a separate stock (Carretta et al. 2023). The abundance of the California/Oregon/Washington stock is estimated at 915 whales based on data from line-transect

surveys from 1991 to 2018 (Becker et al. 2020) with a minimum population size of 509 whales and a PBR of 4.1 whales per year (Carretta et al. 2023). They typically occur as single animals, rather than in groups. Jeffries et al. (2012) reported two sightings of two individuals during ship surveys off Washington and Oregon coasts in the summer of 2011. From July 2004 to September 2008, Oleson et al. (2009) conducted visual and acoustic monitoring efforts in waters off the outer coast of Washington and reported only one sighting of one minke whale during the visual surveys. Calambokidis et al. (2004b) reported four sighting of four individuals during ship surveys off the Washington coast from 1995 to 2002. Brueggeman et al. (1992) encountered four single minke whales, including three off the Oregon coast and one off the Washington coast. Most were on the continental shelf. Minke whales are also known to enter shallow bays and estuaries (Nowak 2003). Green et al. (1993) reported 10 groups of 12 minke whales off the Oregon and Washington coasts between March and May but did not give their locations or indicate the distributions between the two states. Minke whales in the North Pacific Ocean typically prey on euphausiids, Japanese anchovy, Pacific saury, walleye pollock, small fish, and squid (Perrin and Brownell 2002; Nowak 2003).

3.5.3.1.3 Uncommon Marine Mammal Species off the Washington Coast

Nine marine mammal species are rarely, but occasionally, sighted off the Washington coast. They include Guadalupe fur seals, common dolphin, striped dolphin, false killer whale, pilot whale, pygmy sperm whale, Baird's beaked whale, Curvier beaked whale, Hubb's beaked whale, and Stejneger's beaked whale (Table 3-16). Most of these species would be expected to occur seasonally in low numbers in deeper offshore waters. Oleson et al. (2009) reported one sighting of three Curvier beaked whales in June 2006. Brueggeman et al. (1992) observed a small number of false killer whales in the spring and beaked whales in the fall off the Washington coast. Five groups of 21 Baird's beaked whales were also observed, but all were off the Oregon coast during spring and summer, suggesting low occurrence by this species in Washington waters. While there is some limited information on this group of uncommon marine mammals, little is known about their use of waters off the Washington coast. Summary information for each species can be found in Carretta et al. (2023), Young et al. (2023), and Perrin et al. (2002).

3.5.3.2 Other Marine Wildlife

The action area provides breeding and wintering habitat for several species that are listed as threatened or endangered under the ESA and numerous species of seabirds. The following sections provide descriptions of ESA-listed species and other seabird species. The latter discussion is organized by the habitat types with which the species are associated.

3.5.3.2.1 ESA-listed Species and Designated Critical Habitat

The following ESA-listed marine wildlife species are either known to occur or could occur in the action area: marbled murrelet, short-tailed albatross, leatherback sea turtles, green sea turtles, loggerhead sea turtles, and olive ridley sea turtles. The brown pelican and bald eagle also occur in the area but have been delisted. The subsections below provide brief descriptions of species that are currently ESA-listed and that may occur in the action area.

Marbled Murrelet

The marbled murrelet is federally listed as threatened under the ESA (57 FR 45328, October 1, 1992). This species nests in mature and old-growth forests and forages in marine waters. Nearshore marine waters within 1.2 miles (1.9 km) are considered essential to the recovery of the species (USFWS 1997). Newer information indicates murrelets occur out to 5 miles (8 km) from shore with the highest mean densities closer to shore (Raphael et al. 2007). Critical marine foraging habitat includes "proximity of old-growth forests, distribution of rocky shoreline/substrate versus sand shoreline/substrate, and abundance of kelp" (Thompson 1996, as cited in USFWS 1997). Key prey species include Pacific sand lance, Pacific herring, northern anchovy, smelt, and possibly sardines, although the birds will forage on a variety of other small fish and macrozooplankton.

In the action area, marbled murrelets occur throughout the year in the nearshore marine waters and bays. During their pre-basic molt (occurring between July and December), marbled murrelets are flightless for 2 months and must select areas which provide adequate prey resources within swimming distance (Carter and Stein 1995). As indicated in a study by Thompson (1999), marbled murrelets are more abundant closer to shore. In Thompson's study (1996, as cited in USFWS 1997), murrelet density declined with increasing distance from the coastline. Survey data collected under the auspices of the Northwest Forest Plan effectiveness monitoring indicate that murrelet densities in the action area begin to decline 1.9 miles (3 km) from shore (D. Lynch, USFWS Wildlife Biologist, pers. comm., 2006) and Huff et al. (2006) reported that only a small proportion of the population (generally less than 5 percent) is found beyond 1.86 miles (3 km) from shore. From 2001 to 2016, the density of marbled murrelets has increased from 2.47 birds/sq. km to 2.58 birds/sq. km. However, marbled murrelet populations have decreased by annual rates of 4.9 percent (Zone 1–Strait of Juan de Fuca [east of Koitlah Point] and Puget Sound) and 2.4 percent (Zone 2–Strait of Juan de Fuca [west of Koitlah Point] and the Washington coast) in that same period in the action area (USFWS 2019).

Short-tailed Albatross

The short-tailed albatross, which is federally listed as endangered under the ESA, is an extremely rare bird off Washington's coastline (65 FR 46643, July 31, 2001). Since 2002, the Northwest Fisheries Science Center Fisheries Observation Science Program (FOS) has deployed observers on commercial fishing vessels along the U.S. west coast to document sightings of ESA-listed species, including short-tailed albatross. In total, the FOS program has recorded 187 observations of short-tailed albatross from 2002 to 2019, the largest concentration of which was located should of San Francisco Bay, California. Significant concentrations have also been observed off Cape Flattery and Aberdeen, Washington (USFWS 2020). The majority of sightings occur many miles offshore and are associated with the continental shelf break (USFWS 2020). Short-tailed albatross primarily feed on squid (Seattle Audubon Society 2005; Walker et al. 2015). The total population is estimated to be 7,365 birds, with 1,011 breeding pairs observed during the 2018-2019 breeding season (USFWS 2020).

Sea Turtles

Four species of sea turtles occur off Washington's outer coast: the leatherback turtle, green turtle (East Pacific DPS), loggerhead turtle (North Pacific DPS), and olive ridley turtle. Leatherback sea turtles are federally listed as endangered under the ESA, while the three other sea turtles are federally listed as threatened (35 FR 8491, June 2, 1970; 43 FR 32800, July 28, 1978). Leatherback sea turtles are associated with pelagic habitats and while rare, occur with some regularity in the deep waters off the coast of Washington (Bowlby et al. 1994). In addition, these turtles occasionally have been sighted in bays and estuaries, although bays and estuaries are not their preferred habitat (Brown et al. 1995). Leatherback sea turtles' diet consists almost exclusively of jellyfish (Sea Turtle, Inc. 2005). The species does not nest in Washington State. The entire action area is within designated critical habitat for leatherback turtles (77 FR 4170, January 26, 2012).

The other three sea turtle species (green, loggerhead, and olive ridley) are strictly warmer water species, and they occur infrequently off the coast of Washington during the summer (Brown et al. 1995). Higher occurrences of the sea turtles coincide with El Niño years that are characterized by warmer currents in the area. Diets of the three species vary. The green sea turtle is mostly herbivorous and feeds on a variety of sea grasses and marine algae; the loggerhead is primarily carnivorous and feeds on a variety of crabs, jellyfish, shellfish, and sponges; and the olive ridley is omnivorous and feeds primarily on crustaceans, mollusks, and tunicates (Sea Turtle, Inc. 2005). None of these sea turtles nest in Washington State.

3.5.3.2.2 Non-listed Birds and Their Associated Habitats

The action area provides important habitat for bald eagles and some of the largest seabird colonies in the continental United States. The area also provides wintering and other non-breeding habitat for marine birds. Considering all seasonal uses, more than 100 marine bird species use the marine waters, associated beaches, and offshore islands within the action area, with 20 of these species known to nest in the action area (Table 3-17).

Bald Eagle

The bald eagle was de-listed under the ESA on July 9, 2007 (72 FR 37346). These birds are present in Washington State year-round, although individual birds may be present for only a portion of the year (e.g., the wintering period). Bald eagles nest in large, superdominant trees, generally away from intense human activity, and they forage in nearby waters with abundant fish, waterfowl, and seabird prey (Stinson et al. 2001). Perch sites generally consist of large trees along shorelines. Roost sites are typically large trees within forested stands that are located within 0.67 mile (1 km) of foraging areas (Stinson et al. 2001).

Bald eagle nest sites occur throughout the action area's coastline. Most of the Washington State bald eagle wintering population occurs along major salmon rivers (e.g., Skagit, Nooksack, and Columbia Rivers), but the birds also winter along the state's outer coastline and along the Strait of Juan de Fuca, including portions of the action area (Stinson et al. 2001).

Brown Pelican

Brown pelicans also occur in the action area and were de-listed under the ESA in 2009 (74 FR 59444, November 17, 2009). They occur as non-breeding individuals from June to October (Seattle Audubon Society 2005) and forage in marine waters, particularly in shallow areas, including bays and estuaries, and near offshore islands, spits, breakwaters, and open sand beaches. The birds rarely forage more than 40 miles (64 km) from shore (USFWS 2005a). Their diet consists of schooling anchovies, herring, Pacific mackerel, minnow, and sardines (Monterey Bay Aquarium 2003). Brown pelicans roost on offshore islands in the action area (Seattle Audubon Society 2005).

Marine Environments Used by Marine Birds in the Action Area

The marine environments used by marine birds in the action area can be divided into six habitat types: 1) coastal beaches, bays, and estuaries; 2) coastal headlands and islands; 3) nearshore marine waters; 4) inland marine deeper waters; 5) marine shelf; and 6) oceanic waters. Habitat types for marine birds are based on Buchanan et al. (2001) but were modified slightly for

consistency with marine fish habitat types (NMFS 2005c) and marine mammal habitats. This subsection describes these habitats and their associated bird species.

Table 3-17. Marine bird species present in the Makah U&A.

Common Name	***Scientific Name***
LOONS AND GREBES	***GAVIIDAE AND PODICIPEDIDAE***
Common loon	*Gavia immer*
Pacific loon	*Gavia pacifica*
Red-throated loon	*Gavia stellata*
Yellow-billed loon	*Gavia adamsii*
Horned grebe	*Podiceps auritus*
Red-necked grebe	*Podiceps grisegena*
Western grebe	*Aechmophorus occidentalis*
Eared grebe	*Podiceps nigricollis*
TUBENOSES	***PROCELLARIIFORMES (DIOMEDEIDAE, PROCELLARIIDAE AND HYDROBATIDAE)***
Black-footed albatross	*Diomedea nigripes*
Short-tailed albatross	*Phoebastria albatrus*
Laysan albatross	*Diomedea immutabilis*
Buller's shearwater	*Puffinus bulleri*
Flesh-footed shearwater	*Puffinus carneipes*
Pink-footed shearwater	*Puffinus creatopus*
Short-tailed shearwater	*Puffinus tenuirostris*
Sooty shearwater	*Puffinus griseus*
Northern fulmar	*Fulmaris glacialis*
Fork-tailed storm petrel*	*Oceanodroma furcata*
Leach's storm petrel*	*Oceanodroma leuchorhoa*
PELICANS AND CORMORANTS	***PELECANIDAE AND PHALOCROCORACIDAE***
Brown pelican	*Pelecanus occidentalis*
Brandt's cormorant*	*Phalacrocorax penicillatus*
Double-crested cormorant*	*Phalacrocorax auritis*
Pelagic cormorant*	*Phalacrocorax pelagicus*
SWANS, GEESE, AND DUCKS	***ANATIDAE***
Trumpeter swan	*Cygnus buccinator*
Tundra swan	*Cygnus columbianus*

Common Name	***Scientific Name***
Aleutian Canada goose	*Branta canadensis leucopareia*
Brant	*Branta bernicla*
Black scoter	*Melanitta nigra*
Surf scoter	*Melanitta perspicillata*
White-winged scoter	*Melanitta fusca*
Harlequin duck	*Histrionicus histrionicus*
Oldsquaw	*Clangula hyemalis*
Bufflehead	*Bucephala albeola*
Common goldeneye	*Bucephala clangula*
Barrow's goldeneye	*Bucephala islandica*
Greater scaup	*Aythya marila*
Lesser scaup	*Aythya affinis*
Canvasback	*Aythya valisineria*
Red-breasted merganser	*Mergus serrator*
Common merganser	*Mergus merganser*
Hooded merganser	*Lophodytes cucullatus*
Gadwall	*Anas strepera*
Eurasian widgeon	*Anas penelope*
American widgeon	*Anas americana*
Mallard	*Anas platyrhynchos*
Green-winged teal	*Anas crecca*
Blue-winged teal	*Anas discors*
Northern shoveler	*Anas clypeata*
Northern pintail	*Anas acuta*
Ruddy duck	*Oxyura jamaicensis*
RAILS, GALLINULES, AND COOTS	***RALLIDAE***
American coot	*Fulica americana*
EAGLES, OSPREYS, AND FALCONS	***FALCONIFORMES***
Bald eagle*	*Haliaeetus leucocephalus*
Osprey*	*Pandion haliaetus*
Peregrine falcon*	*Falco peregrinus*
OYSTERCATCHERS	***HAEMATOPODIDAE***
Black oystercatcher*	*Haematopus bachmani*

Common Name	***Scientific Name***
PLOVERS	***CHARADRIIDAE***
Killdeer*	*Charadrius vociferous*
Semipalmated plover	*Charadruis semipalmatus*
American golden plover	*Pluvialis dominicus*
Black-bellied plover	*Pluvialis squatarola*
SANDPIPERS, TURNSTONES, SURFBIRDS, AND PHALAROPES	***SCOLAPACIDAE***
Black turnstone	*Arenaria melanocephala*
Ruddy turnstone	*Arenaria interpres*
Surfbird	*Aphriza virgata*
Marbled godwit	*Limosa fedoa*
Greater yellowlegs	*Tringa melanoleuca*
Lesser yellowlegs	*Tringa flavipes*
Spotted sandpiper*	*Actitis macularia*
Whimbrel	*Numenius phaeopus*
Wandering tattler	*Heteroscelus incanus*
Long-billed dowitcher	*Limnodromus scolopaceus*
Short-billed dowitcher	*Limnodromus griseus*
Rock sandpiper	*Calidris ptilocnemis*
Baird's sandpiper	*Calidris bairdii*
Dunlin	*Calidris alpina*
Least sandpiper	*Calidris minutilla*
Sanderling	*Calidris alba*
Western sandpiper	*Calidris mauri*
Red phalarope	*Phalaropus fulicaria*
Red-necked phalarope	*Phalaropus lobatus*
Northern phalarope	*Lobipes lobatus*
JAEGERS AND SKUAS	***STERCORARIINAE***
Long-tailed jaeger	*Stercorarius longicaudus*
Parasitic jaeger	*Stercorarius parasiticus*
Pomarine jaeger	*Stercorarius pomarinus*
South polar skua	*Catharacta mccormicki*
GULLS AND TERNS	***LARIDAE***
Bonaparte's gull	*Larus philadelphia*

Common Name	***Scientific Name***
California gull	*Larus californicus*
Glaucous-winged gull*	*Larus glaucescens*
Heerman's gull	*Larus heermanni*
Herring gull	*Larus argentatus*
Mew gull	*Larus brachyrhynchos*
Ring-billed gull	*Larus delawarensis*
Sabine's gull	*Xema sabini*
Thayer's gull	*Larus thayeri*
Western gull*	*Larus occidentalis*
Black-legged kittiwake	*Rissa tridactyla*
Caspian tern	*Sterna caspia*
Common tern	*Sterna hirundo*
Forster's tern	*Sterna forsteri*
Arctic tern	*Sterna paradisaea*
ALCIDS	***ALCIDAE***
Ancient murrelet	*Synthliboramphus antiquum*
Cassin's auklet*	*Ptychoramphus aleutica*
Common murre*	*Uria aalge*
Marbled murrelet	*Brachyramphus marmoratus*
Pigeon guillemot*	*Cepphus columbia*
Rhinoceros auklet*	*Cerorhinca monocerata*
Tufted puffin*	*Lunda cirrhata*
KINGFISHERS AND HERONS	***ALCEDINIDAE AND ARDEIDAE***
Belted kingfisher*	*Ceryle alcyon*
Great blue heron*	*Ardea herodias*
Green heron	*Butorides striatus*
American bittern	*Botaurus lentiginosus*

* = species known to nest in the area.

Coastal Beaches, Bays, and Estuaries

The action area includes several beaches, bays, and estuaries. Bays and estuaries provide concentrations of nutrients and forage for marine birds and shorebirds such as loons, grebes, mergansers, scoters, dunlins, plovers, and sandpipers. Beaches, particularly those with fine-

grained sand, provide forage areas for several shorebird species, including sanderlings, dunlins, and killdeer. Human-made structures, such as jetties, pilings, and buoys, provide important roosting habitat for cormorants, gulls, and other birds. Approximately 49 marine bird species in Washington State are closely associated with beaches, bays, and estuaries; 37 marine bird species are generally associated; and another 16 marine bird species occasionally use beaches, bays, and estuaries (Table 3-18). Bird densities along the beaches and in the bays and estuaries are particularly high during winter and during spring and fall migration periods (Buchanan et al. 2001).

Table 3-18. Marine bird species richness in marine habitats based on habitat association.

Habitat Type	Habitat Use (recorded as number of species)			
	Closely Associated[1]	Generally Associated[2]	Occasional Use[3]	Total
Beaches, bays, and estuaries	49	37	16	102
Headlands and islands	22	14	2	38
Nearshore marine	31	26	10	67
Inland marine	21	17	9	47
Marine shelf	28	15	9	52
Oceanic	18	7	3	28

Source: Table adapted and modified from Buchanan et al. (2001). Because some species are associated with more than one habitat type, totals within columns are not additive.

[1] Closely associated: A species is widely known to depend on a habitat for part or all of its life-history requirements.

[2] Generally associated: A species exhibits a high degree of adaptability and may be supported by a number of habitats. These habitats play a supportive role for the species' maintenance and viability.

[3] Occasional use: A species demonstrates occasional use of a habitat. The habitat provides marginal support to the species for its maintenance and viability.

Coastal Headlands and Islands

This habitat type includes coastal headlands and bluffs, rocky cliffs, and offshore rocks and islands. In the action area, steep headlands, bluffs, and cliffs are used by ledge-nesting birds, including peregrine falcons, pelagic cormorants, and common murres. Offshore islands and rocks support large breeding colonies of seabirds (Speich and Wahl 1989; Buchanan et al. 2001; USFWS 2005b).

Comprehensive information on seabird colony breeding densities in Washington is available from Speich and Wahl (1989). These researchers summarized seabird colony data from surveys conducted from 1978 to 1982. In the Cape Flattery survey region, which extends along the outer Washington coast from Cape Flattery to Carroll Island and inland along the Strait of Juan de Fuca to Sail Rock, surveyors documented 13 breeding seabird species, the most common of which were Cassin's auklets, Leach's storm-petrels, and tufted puffins (Table 3-19). Sites with the

highest recorded abundance of seabird colonies (all species combined) in this region include Carroll Island (18,876 breeding seabirds), Bodelteh Island (11,618 breeding seabirds), and the Tatoosh Islands (3,528 breeding seabirds). In addition to the survey sites from the Cape Flattery survey region, the Speich and Wahl report includes data from Jagged Island, near the southern boundary of the Makah U&A. The surveyors recorded 37,057 breeding seabirds on Jagged Island, including 20,000 Leach's storm-petrels, 7,800 tufted puffins, and 8,000 Cassin's auklets (Speich and Wahl 1989).

Table 3-19. Breeding seabird species and abundance in the vicinity of Cape Flattery.

Species	Approximate Number of Breeding Birds
Cassin's auklet	24,000
Leach's storm-petrel	11,000
Tufted puffin	8,700
Glaucous-winged or western gulls	4,400
Fork-tailed storm-petrel	3,700
Common murre	900
Pelagic cormorant	900
Rhinoceros auklet	200
Double-crested cormorant	150
Pigeon guillemot	150
American black oystercatcher	60
Brandt's cormorant	10

Source: Speich and Wahl (1989)

A variety of shorebirds (such as plovers, oystercatchers, sanderlings, and sandpipers) uses offshore rocks and islands and their associated tidal areas for foraging and roosting. The larger islands (including Ozette Island and the Bodelteh Islands) are used by several raptors (such as peregrine falcons) for foraging and occasionally nesting. Passerines (such as swallows and sparrows) use these islands for nesting, foraging, and migration resting areas (USFWS 1985). Nesting great blue herons have also been documented on the larger islands (USFWS 1985). The island vicinities are also used by migrating and wintering marine birds (such as gulls, loons, grebes, and scoters). Buchanan et al. (2001) indicate that 22 marine bird species in Washington are closely associated with headlands and offshore islands (Table 3-18).

Nearshore Marine Zone

The nearshore marine habitat zone includes those marine waters along shorelines that are not significantly affected by freshwater inputs (i.e., excludes bays and estuaries)

(Buchanan et al. 2001). Nearshore marine habitat includes both nearshore marine waters and inland marine deeper waters. Nearshore marine waters extend from the high tide line to a depth of approximately 66 feet (20 m) (Buchanan et al. 2001). Typical birds that forage in nearshore marine waters include western grebes, Brandt's cormorants, common murres, sooty shearwaters, and rhinoceros auklets; the latter three species may concentrate in large numbers during the summer (Buchanan et al. 2001). A variety of common marine birds (e.g., phalaropes, other shorebirds, and waterfowl) also uses nearshore marine habitats as migration corridors (Buchanan et al. 2001). Buchanan et al. (2001) indicate that 31 bird species in Washington are closely associated with nearshore marine waters (Table 3-18).

Within the action area, inland marine deeper waters include waters ranging from 66 feet (20 m) deep within the western portion of the Strait of Juan de Fuca up to 120 feet (37 m) deep. Species richness is relatively low in this area, with richness and bird densities higher in winter than summer (Table 3-18) (Buchanan et al. 2001). Common wintering birds in the area include western grebes, common murres, scoters, phalaropes, mergansers, buffleheads, and goldeneyes (Buchanan et al. 2001; Nysewander et al. 2004). Murres are also common in summer, along with cormorants and auklets.

Continental Shelf

Along the outer coast of Washington, the continental shelf habitat includes those marine waters from approximately 120 to 600 feet (37 to 183 m) deep (Buchanan et al. 2001, as modified by NMFS 2005c). As with the nearshore marine habitat, the continental shelf provides foraging habitat and a migration route for a variety of marine birds. In Washington, 28 birds are highly associated with continental shelf habitat (Table 3-18). Typical birds that forage in the shallower portions of the continental shelf are common murres, rhinoceros auklets, tufted puffins, and sooty shearwaters. Typical birds in the outer, deeper portions of the continental shelf include albatrosses, fulmars, storm-petrels, and shearwaters (in addition to the sooty shearwater). Species use varies by season, with the most species during winter and the fewest species during summer (Buchanan et al. 2001). Bird densities are greatest in summer and early fall, when both summer residents and migrant phalaropes, jaegers, terns, and alcids are present (Buchanan et al. 2001).

Continental Slope

Oceanic waters include the marine slope (waters from 600 to 4,200 feet [183 to 1,280 m] deep) and offshore areas (waters greater than 1.25 miles [2 km] deep) (Buchanan et al. 2001, as modified by NMFS 2005c). Species richness and bird densities in oceanic waters are diminished

compared to the other marine habitats, presumably because of the lower abundance of food in oceanic waters (Table 3-18) (Buchanan et al. 2001). As with the continental shelf, bird densities in oceanic waters are greatest in late summer to early fall, when both summer residents and fall migrants are present. Characteristic bird species of the continental shelf include the black-footed albatross, fork-tailed storm-petrel, northern fulmar, herring gull, and black-legged kittiwake (Buchanan et al. 2001).

3.5.3.3 Sensitivity of Wildlife to Noise and Other Disturbance

This section describes the sensitivity of marine wildlife species to noise and other disturbance. Anthropogenic noise can be either transient or continuous and can result in a variety of effects with consequences ranging from none to severe (Würsig and Richardson 2002). Sources of transient noise include helicopters, planes, and explosions; sources of continuous noise include ships underway and dredging activities. The discussion that follows focuses on wildlife sensitivity to noise potentially generated from activities associated with a Makah whale hunt, including aircraft overflights, boat traffic, and use of gunfire or explosives. See Section 3.11, Noise, for a discussion of key concepts related to noise, as well as existing noise levels in the action area.

Marine mammals may respond to noise and other disturbance in many ways, including changes in behavior, avoidance reactions, masking, hearing impairment, and nonauditory physiological effects and stress (Würsiig and Richardson 2002). For marine mammals that rely on sound to communicate, find prey, avoid predators, and likely to navigate, perturbations involving noise could have negative impacts on fitness or survival.

Effects of disturbance on marine birds can range from temporary and minor behavioral changes, such an alert response, to reactions with potentially negative effects on reproductive success, such as nest abandonment. Bird responses depend on a variety of factors as described further in the subsections below (Carney and Sydeman 1999; Point Reyes Bird Observatory 2005). Colonial nesting birds are particularly vulnerable to disturbance because of their high nesting densities and group behavior; when one bird responds to a given disturbance (e.g., flushing from its nest), other birds often follow (Rodgers and Smith 1995).

3.5.3.3.1 Aircraft Overflights

Based on a review of studies on the response of species found in west coast National Marine Sanctuaries, Moore (1997) concluded that aircraft overflights "can and do disturb wildlife." The regulations governing the OCNMS (15 CFR 922.152(7), revised January 26, 2012) state that failure to maintain a minimum flight altitude of 2,000 feet (610 m) over certain portions of the

Sanctuary is presumed to disturb marine mammals or seabirds. These restrictions are described in greater detail in Subsection 3.1.1.1.2, Designation and Regulatory Overview (of the OCNMS). Disturbance varies by species and the specifics of the situation. The following paragraphs discuss disturbance of birds and marine mammals (i.e., wildlife likely to use habitats in the action area) by aircraft.

Reactions of some bird species may range from increased vigilance and attentiveness (including scanning by head-turning) to flushing from a nest or perch (Brown 1990; Stalmaster and Kaiser 1997; Giese and Riddle 1999; Ward et al. 1999). In similar circumstances, other species may not react at all (Parrish et al. 2005). In their review of overflight and wildlife disturbance, the National Park Service (1995) indicated mixed results, with some species exhibiting response to overflights, but other species showing minimal or no response. At least one study (of peregrine falcons) indicated no apparent change in parental behavior from low (less than 500 feet [152 m]) military overflights, while another study (of waterfowl) found minimal disturbance caused by military overflights (Parrish et al. 2005). With increasing numbers of overflights, some wildlife may habituate to aircraft noise (e.g., black ducks), whereas other species will not (e.g., wood ducks, black brant, emperor, and Canada geese) (Conomy et al. 1998; Ward and Stein 1989). In a study of experimental overflights at lakes, Komenda-Zehnder et al. (2003) found that the behavior of waterbirds was not substantially altered by fixed-wing aircraft flying at least 1,000 feet (305 m) above ground level and helicopters flying at least 1,500 feet (457 m) above ground level. In that study, birds disturbed by low-flying aircraft returned to relaxed behavior (e.g., resting, preening, feeding) within 5 minutes of overflights.

In general, conclusions based on responses of one species are not necessarily applicable to another species (Manci et al. 1988); similarly, responses to one aircraft type may differ from responses to other types, even within a single species (National Park Service 1995; Ward et al. 1999). In a field study using playback of recordings of overflights to measure effects on seabirds, Brown (1990) found that the level of response increases with increasing noise. This is notable because not all aircraft produce the same amount of noise; thus, a relatively quiet aircraft flying nearby may cause less disturbance than a noisier aircraft farther away (Parrish et al. 2005). In a study of nesting osprey, for example, Trimper et al. (1998) found that adult osprey did not appear to be disturbed by military overflights at various distances, approximately 2 miles (3.2 km) from the nest, but reacted strongly to float planes approaching within 4.8 miles (7.7 km). Parrish et al. (2005) noted that helicopters typically cause more disturbance than other aircraft types. Similarly, Komenda-Zehnder et al. (2003) found that the disturbance effect of helicopters was greater than

that of fixed-wing aircraft. The helicopters used in that study were larger and louder than the airplanes, which makes it impossible to determine which of two factors (visual or acoustic cues), was responsible for the differences.

Based on observations of marine birds and aircraft overflights at Tatoosh Island, Parrish et al. (2005) drew the following general conclusions:

1. Aircraft type has a substantial effect on disturbance level, independent of altitude, with louder aircraft having a greater effect.
2. Immediate geomorphology has an effect on disturbance level, as concave surfaces (bowls) concentrate sound, whereas convex surfaces dispel sound.
3. The timing of the disturbance event within the breeding season has an effect on disturbance level; earlier in the season (before egg laying), birds are more likely to exhibit signs of disturbance (culminating in temporary evacuation of nesting or loafing sites), whereas later in the season (when pairs have eggs or chicks), birds may remain on nests even during elevated levels of disturbance.
4. Not all species respond equally. Disturbance varies by species and the specifics of the situation such that even related species differ in their responses. Disturbance may also be minimal or not occur. The lateral distance of the aircraft also strongly affects whether wildlife are disturbed. The correlation between distance and increased disturbance may result from increasing noise levels. The sudden appearance of aircraft, especially in the case of infrequent overflights, may also disturb wildlife.
5. Based on observed disturbance caused by overflights, several authors conclude that aircraft altitude restrictions should be developed or maintained, with recommendations for the distance aircraft should stay from wildlife ranging from 500 to 5,000 feet (152 to 1,524 m), depending on the species under consideration (Giese and Riddle 1999; Grubb and Bowerman 1997; Stalmaster and Kaiser 1997).
6. For any particular aircraft type, flying at lower altitudes generally increases the level of disturbance.

Few studies have documented the response of marine mammals to overflights (Parrish et al. 2005). Studies measuring the response of marine animals to noise were summarized by Myrberg (1990), who noted numerous reports of marine mammal disturbance caused by man-made sources, including offshore oil drilling and shipping. Responses of marine mammals to aircraft vary by

species, aircraft type, approach distance and altitude, and pre-disturbance behavior. In a study of bowhead and beluga whales, Patenaude et al. (2002) found that helicopters cause more disturbance than other types of aircraft, and that beluga whales responded more often to all noise than bowhead whales. Aircraft flying at low altitude, at close lateral distances, and above shallow water tend to elicit stronger responses than aircraft flying higher, at greater lateral distances, and over deep water (Patenaude et al. 2002; Smultea et al. 2008). Würsig et al. (1998) found that whales and dolphins milling or resting at the surface are most sensitive to disturbance from aircraft. In a study of the responses of sperm whales to aerial whale-watching trips, Richter et al. (2006) found a very high degree of variation in responses among individuals. Transient whales were less tolerant of aerial whale-watching activities, while resident whales appeared to cope better, possibly because of habituation (Richter et al. 2006).

Pinnipeds are susceptible to disturbance while in the water or on land. Calkins and Pitcher (1982) found that disturbance from aircraft and vessel traffic has extremely variable effects on hauled-out sea lions, ranging from no reaction at all to complete and immediate departure from the haulout (i.e., a stampede). When sea lions are frightened off rookeries during the breeding and pupping season, pups may be trampled or, in extreme cases, abandoned (Calkins and Pitcher 1982). Insley (1993) used sound recordings, sound pressure measurements, and video recordings to study the effect of aircraft overflights on northern fur seal behavior at St. George Island, Alaska. He found that if pilots followed the prescribed flight path and altitude and did not pass over the seal rookeries there was no discernible impact on the seals.

Response to aircraft may also depend on overflight frequency. With increasing numbers of overflights, some wildlife may habituate to aircraft noise, whereas other species will not (Conomy et al. 1998). Conversely, sensitization may also occur. For example, the response of harbor seals increased with greater overflight occurrence (Johnson 1977 as cited in Moore 1997).

Some specific study results relevant to the action alternatives in this FEIS include:

1. In a review paper of marbled murrelets, Nelson (1997) stated that aircraft flying at low altitudes are known to cause marbled murrelets to dive, although the specific altitude was not mentioned.

2. Pilots are required to stay more than 2,000 feet (610 m) above ground level when flying over the OCNMS; failure to maintain that minimum flight altitude over certain portions of the Sanctuary is presumed to disturb marine mammals or seabirds (15 CFR

922.152(7)). Federal Aviation Administration navigational charts have been revised to include information on the Sanctuary's overflight regulations.

3. Several studies have documented effects of aircraft on foraging and nesting eagles. In a study of nesting eagles in Michigan, average eagle flushing distance was approximately 0.5 mile (0.8 km) for jets, 0.75 mile (1.21 km) for light planes, and 0.4 mile (0.64 km) for helicopters (Grubb et al. 1992). In a study on the effects of helicopters on nesting eagles in northwestern Washington, Watson (1993) reported that 53 percent of nesting eagles were disturbed (i.e., alert and flush behavior) when helicopters approached within 1,500 feet (457 m) of eagle nests. In a study of wintering bald eagle response to military activities at Fort Lewis, Washington, investigators reported that most eagles flushed when helicopters approached within 1,000 feet (305 m) (Stalmaster and Kaiser 1997). In their National Bald Eagle Management Guidelines (2007), USFWS recommends that aircraft maintain a distance of at least 1,000 feet (305 m) from eagle nests during the nesting season, except where eagles have demonstrated tolerance for such activity.

4. In a study of the effects of low-level jet aircraft overflights along the Naskaupi River, Labrador, Canada, nesting osprey behavior did not differ significantly between pre- and post-overflight periods, and adult osprey did not appear agitated or startled when overflown by jet aircraft (at overflights as low as 100 feet (31 m) above ground) (Trimper et al. 1998). Osprey were attentive and occasionally flushed from nests when float planes entered their territories.

5. At a mixed cliff-nesting colony of fulmars, shags, herring gulls, kittiwakes, guillemots, razorbills, and puffins on the Aberdeenshire coast of Scotland, aircraft flying at heights about 300 feet (91 m) above the cliff-top did not affect the attendance of incubating and brooding birds (Dunnet 1977).

3.5.3.3.2 Boat Traffic

A study on the Pribilof Islands in summer 1990 measured the effect of direct noise (airplanes, land vehicles, ships, and construction activities) on northern fur seal behavior at rookeries on St. Paul Island (Insley 1992). Noise levels were measured on land near the rookeries as ships moved toward and away from the island during all hours of the day. Ship noise at the rookeries averaged approximately 82 dB in a frequency range between 60 and 300 hertz (Hz). No effect from ship noise was observed in fur seal behavior during this study. In contrast, Insley et al. (2003) found that fur seals foraging at sea changed their direction of movement when commercial trawl vessels were nearby. As summarized by Würsig and Richardson (2002), the strongest

components of sound from many of the major anthropogenic sources are below 1,000 Hz. Peak sound intensities of small powerboats are generally in the frequency range of 350 to 1,200 Hz (Barlett and Wilson 2002).

Marine birds can also be sensitive to disturbance from boat traffic. Bird responses to boat traffic range from changing body position to abandoning a foraging attempt to flushing from a nest (Burger 1998; Carney and Sydeman 1999; Point Reyes Bird Observatory 2005). Responses of birds depend on a variety of factors, including the time of year; type, speed, and distance of boats from the birds; frequency of disturbance; bird species; and bird activity (e.g., foraging, roosting, or nesting) (Burger 1998; Rodgers and Schwikert 2002; Ronconi and St. Clair 2002). In general, mobile birds (e.g., foraging birds) move away from areas with high boat traffic, while nesting birds show behavioral, growth, or reproductive effects, with varying degrees of habituation (Kuletz 1996; Burger 1998).

Some specific study results relevant here include:

1. Of the hundreds of murrelets that researchers encountered with their skiff each day in Alaska's Auke Bay and Fritz Cove, most of the birds reacted to the skiff by paddling away; only a few of the birds reacted by flying away (Speckman et al. 2004). However, on eight separate occasions, murrelets that were holding fish crosswise in their bills swallowed the fish on approach of the skiff, generally when the skiff was within 15 to 130 feet (5 to 40 m) of the bird. The birds holding fish were presumed to be parents about to make food deliveries to their chicks (as consistent with other alcids). Consequently, skiff disturbance represented a loss in food for the chicks. The researchers concluded that such disturbance could be detrimental to murrelets in areas where prey are relatively scarce, where birds' inland nests are far from marine foraging areas, or where boat traffic is concentrated in waters immediately adjacent to nesting areas.

2. Observers conducting boat surveys for marbled murrelets noted that the birds dove more often than flew when a boat approached. If approached slowly and from an angle, however, the birds paddled away from the boat (E. Neatherlin, WDFW, pers. comm., 2003, as cited in USFWS 2003).

3. In a study in Finland, boat disturbance (at levels of 3.5 to 8.5 disturbances per day) lengthened the swimming distances of velvet scoter ducklings and reduced the time used for feeding (Mikola et al. 1994). The birds showed a response to the boats when the boats were within 100 feet (30.5 m) of the ducks. Birds disturbed more frequently than average

were smaller than birds disturbed less frequently. The frequency of predatory gull attack on the ducks was 3.5 times higher in disturbed areas than undisturbed areas.

4. In a study in Florida, researchers investigated the flushing distance of 23 waterbird species to personal watercraft and outboard-powered boats (Rodgers and Schwikert 2002). Flushing distance for foraging and loafing birds varied by species and individual and boat type. Average flush distance by species ranged from 77 feet (24 m) (Forster's tern) to 190 feet (58 m) (osprey) of outboard-powered boats and 64 feet (20 m) (least tern) to 162 feet (49 m) (osprey) for personal watercraft. Based on their study results, the researchers suggested buffer zones of 590 feet (180 m) for wading birds, 490 feet (149 m) for osprey, 460 feet (140 m) for terns and gulls, and 330 feet (101 m) for plovers and sandpipers to minimize disturbance at foraging and loafing sites.

5. In a study at a black skimmers nesting colony in New Jersey, Burger et al. (2010) found that reproductive stage had the greatest effect on the responses of birds to approaching boats. During the pre-egg-laying period, skimmers flushed from their nests when boats were 330 feet (101 m) away, on average, compared to a flushing distance of 140 feet (43 m) when they had small chicks on the nest. The time for skimmers to return to the nesting colony after a disturbance event also varied seasonally, with birds taking substantially longer to return during the pre-egg period (approximately 9.5 minutes) than during the hatching period (approximately 0.7 minutes). The researchers recommended a set-back distance of approximately 390 feet (119 m) from the perimeter of the nesting colony.

6. Rojek et al. (2007) documented vessel disturbances of common murres at three breeding colonies in central California. Most boat disturbance occurred when vessels approached within 164 feet (50 m) of active nesting areas and remained in the area for extended periods. Such disturbances resulted in the loss of both eggs and chicks.

7. Several studies have documented effects of boats on foraging and nesting eagles. In a study of nesting eagles in Michigan, average eagle flushing distance was 360 feet (110 m) for power boats and about 1,000 feet (305 m) for canoes/kayaks (Grubb et al. 1992). Foraging eagles on the Columbia River maintained an average distance of 1,300 feet (396 m) from stationary boats. In the presence of boats, the birds reduced their feeding time and number of foraging attempts (McGarigal et al. 1991). In a study of wintering bald eagle response to military activities at Fort Lewis, Washington, investigators reported that most eagles flushed when boats approached within 330 feet (101 m) (Stalmaster and Kaiser 1997). In a study of wintering eagles along the Nooksack

and Skagit Rivers in Washington, researchers reported that average distance for perched eagles flushed by a canoe was approximately 500 to 550 feet (152 to 168 m), and average flush distance for eagles standing or feeding on the ground was approximately 750 to 900 feet (229 to 274 m), although more sensitive eagles flushed at distances out to approximately 1,150 feet (351 m) (Knight and Knight 1984). In their National Bald Eagle Management Guidelines (2007), USFWS recommends that within 300 feet (91 m) of eagle nests during the nesting season (1) concentrations of noisy vessels (e.g., commercial fishing boats and tour boats) should be avoided, except where eagles have demonstrated tolerance for such activity; and (2) other motorized boat traffic should attempt to minimize trips and avoid stopping in the areas where feasible, particularly where eagles are unaccustomed to boat traffic.

Marine birds may be sensitive to underwater noise when they are diving to catch fish. Effects can range from behavioral changes (e.g., delayed or aborted foraging attempts, avoidance of potential foraging areas) to physical injury (USFWS 2003). Based on a review of studies of the effects of noise on animals in underwater environments, USFWS (2003) estimated that peak sound pressure levels greater than 180 dB have the potential to cause physical injury. A recent study of noise levels from small powerboats found peak levels of 145 to 150 dB, primarily in the 350- to 1,200 Hz frequency range (Barlett and Wilson 2002). Similarly, Hildebrand (2005) reported peak noise levels of 140 dB for small fishing vessels. Higher noise levels are associated with larger vessels; Richardson et al. (1995) provided estimates of 171 dB for a tug and barge and 181 dB for a large supply ship.

3.5.3.3.3 Gunfire and Explosives

Studies on the effects of non-lethal gunfire on marine birds are rare. Investigators did study the effect of military shooting ranges on the birds of the Wadden Sea, although effects may have been confounded by aircraft effects (Kuesters and Van Raden 1998). The investigators stated that the reactions of the birds to bombing and shooting air-to-ground missiles and machine guns from low-flying planes varied from continuing feeding to alert behavior to spontaneous flight. Reaction intensity depended on the sequence in which the weapons were fired (i.e., birds were more likely to become habituated if the shooting started with low-noise weapons) and particularly on the tide, with higher tides (and associated concentrations of birds on their high-tide roosts) eliciting stronger responses. In a study of wintering bald eagle response to military activities at Fort Lewis, Washington, investigators reported that most eagles were not “overly disturbed” by artillery and small arms fire (Stalmaster and Kaiser 1997). In a study of nesting eagles in Michigan, average

eagle flushing distance was approximately 1,600 feet (488 m) for gunfire and 5,000 feet (1,524 m) for artillery fire (Grubb et al. 1992).

Indirect evidence of the effects of gunfire on birds can be obtained from results of bird hazing activities at aquaculture facilities, hydroelectric facilities, agricultural sites, and oil spills. In general, gunfire and other pyrotechnics initially cause foraging birds to flush, but the birds usually become habituated to the gunfire over time (Bomford and O'Brien 1990; Salmon and Marsh 1991; Bechard and Marquez-Reyes 2003).

3.5.3.3.4 Marine Mammals and Underwater Noise

Within animals, hearing characteristics vary among individuals, sex and age classes, populations, and species. Hearing capabilities of marine mammals have been studied for just over 20 of approximately 125 species (Richardson et al. 1995; Wartzok and Ketten 1999; Würsig and Richardson 2002). The species studied are limited to those small enough to be held in captivity. Traditionally, direct hearing measurements have involved trained responses; more recently, electrophysiological methods have been used to measure neural activity in animals presented with sound. For larger or rare species, hearing must be estimated from mathematical models based on anatomy, inferred from the sounds they produce, or from reactions to sounds in their environment.

Hearing and sound production are highly developed in all studied cetacean species. Cetaceans rely heavily on sound and hearing for communication and sensing their environment (Watkins and Wartzok 1985; Tyack 2000). Of all mammals, cetaceans have the broadest acoustic range and the only fully specialized ears adapted for underwater hearing. Little information is available, however, for individual hearing capabilities in most cetacean species (Ketten 2000).

Of the cetaceans, baleen whales are thought to be most sensitive to low-frequency sounds (approximately 7 Hz to 35 kHz) based on characteristics of their auditory morphology, behavioral responses, and sound production (NMFS 2018a). Refer to Subsection 3.4.3.6.5, Known and Potential Anthropogenic Impacts, Offshore Activities and Underwater Noise, for more information about gray whales and marine noise. No direct empirical data exist on the hearing of baleen whales. Most odontocetes (toothed cetaceans, such as killer whales, other dolphins and porpoises, and sperm whales) have functional hearing across a broader range of mid to high frequencies (from 150 Hz to 160 kHz) (NMFS 2018a). Odontocetes communicate mainly above 1,000 Hz and use echolocation signals as high as 150 kHz (NFMS 2018a). A few odontocetes, including harbor porpoises and river dolphins, hear relatively similarly in this broad range, but

appear to be specialized for hearing sounds at very high frequencies (approximately 275 Hzto 160 kHz or higher) (NMFS 2018a).

Pinnipeds (seals, sea lions, and walrus) are fundamentally different from other marine mammals, because they are amphibious mammals performing important life functions both above and below water. Consequently, they have a number of auditory adaptations enabling fairly sensitive hearing across wide frequency ranges both in air and water (Richardson et al. 1995; Kastak and Schusterman 1998). Pinnipeds can be segregated into two functional groups based on their underwater hearing capabilities: 1) otariids (sea lions and fur seals), which have been shown to be sensitive to a fairly wide range of mid frequencies (approximately 50 Hz to 86 kHz); and 2) phocids (true seals) and walruses, which generally are capable of hearing across a wide range of low to mid frequencies (approximately 60 Hz to 39 kHz) (NMFS 2018a). The differences in hearing bandwidth in air are less striking between the phocids and otariids; in both taxa, functional bandwidth is narrower in air than in water.

Ketten (1998) reported that there are no conventional audiometric data available for sea otters, but research on river otters indicates a functional hearing range in air of approximately 450 to 35,000 Hz and a peak sensitivity of 16,000 Hz.

Noise and Marine Mammal Physiological Effects

Noise exposure may result in a range of effects on auditory and non-auditory systems. Noise may be detectable but have no effect on a mammal's hearing or physiology. The presence of noise may mask signals of interest (such as calls of other animals) (Bain and Dahlheim 1994; Erbe 2002; Southall et al. 2003). Intense or prolonged exposure may result in either temporary or permanent changes in hearing sensitivity (Schlundt et al. 2000). Sound exposure may also induce physical trauma to non-auditory structures (Jepson et al. 2003; Fernandez et al. 2005), although much remains uncertain regarding the exact mechanisms. Physical effects, such as direct acoustic trauma, can be influenced by a marine mammal's frequency range of hearing compared to a sound source, as well as the intensity and energy from the source that are received by the animal (Nowacek et al. 2007; Southall et al. 2003). Because marine mammals in the action area rely on underwater sounds for various purposes, any strong anthropogenic sounds at relevant frequencies might have an effect.

Noise and Marine Mammal Behavior

Most studies of the effects of noise on marine mammal behavior are observational rather than experimental. Behavioral responses can range in severity from no observable response to panic

and stranding (Southall et al. 2003; Ellison et al. 2012). Behavioral responses of more typical and moderate severity may take many forms, including subtle changes in surfacing and breathing patterns, changes in vocalization rate or intensity, or active avoidance or escape from the vicinity of the noise source. Bowhead whales have been observed altering their diving and blowing behavior in response to human noises (Richardson et al. 1986). Many whale species have been seen to cease vocalizing in response to human noises. These include right whales (Watkins 1986), bowhead whales (Wartzok et al. 1989), sperm whales (Watkins and Schevill 1977; Bowles et al. 1994), humpback whales (Sousa-Lima and Clark 2012), and pilot whales (Bowles et al. 1994). Other responses include humpback whales lengthening their song cycles (Miller et al. 2000) and moving away from mid-frequency sonar (Maybaum 1993) or tourist boats (Sousa-Lima and Clark 2012), beluga whales adjusting their echolocation clicks to higher frequencies (Au et al. 1985), and gray whales avoiding air gun noise (Malme et al. 1984). Average speed and distance of nearby vessels have both been found to affect the behavior of Southern Resident killer whales in the inland waters of Washington State (Holt et al. 2021a and 2021b). In contrast, some observers (e.g., Tyack and Clark 1998; Fristrup et al. 2003) have reported instances in which whales did not respond to human sounds.

Many factors can affect the broad range of marine mammals' behavioral responses to sound, which makes their behavioral responses hard to predict (NRC 2005; Ellison et al. 2012); the received level of sound intensity contributes to such responses (Southall et al. 2003). Responses may also vary depending on the context of the sound exposure (i.e., whether the animal is motivated to be in an area because of feeding or breeding or whether the sound source is novel) as well as the animal's age and sex. For example, mother-calf pairs of gray whales are considered more sensitive to disturbance by whale-watching vessels than other age or sex classes (Tilt 1985). Responses also appear to be affected by the location of the source relative to the animal, the motion of the source, and the onset and repetition of the sound (Hildebrand 2005; NRC 2003; Ellison et al. 2012).

Jensen et al. (2009) studied the potential for sounds from recreational motorboats (including boats used for whale-watching excursions) to interfere with communication by cetacean species in shallow-water habitats (bottlenose dolphins) and deep-water habitats (short-finned pilot whales). They found that small vessels traveling at 5 knots in shallow water can reduce the communication range of bottlenose dolphins within 164 feet (50 m) by 26 percent. Similar vessels traveling at similar speeds in quieter deep-water habitats can reduce the communication range of pilot whales

by 58 percent (Jensen et al. 2009). Holt et al. (2009) found that Southern Resident killer whales increase their call amplitude by 1 dB for every 1 dB increase in background noise levels.

In a study that used acoustic tags and controlled exposure experiments with North Atlantic right whales, Nowacek et al. (2004) examined the effects of shipping noise on marine mammal behavior. Five of six individual whales responded strongly (interrupted dive pattern and rapid ascent to the surface) to the presence of an artificial alarm stimulus (series of constant frequency and frequency modulated tones and sweeps) but ignored playbacks of vessel noise. More information about the effects of noise on gray whale behavior can be found in Subsection 3.4.3.6.5, Known and Potential Anthropogenic Impacts, Offshore Activities and Underwater Noise.

3.6 Economics

3.6.1 Introduction

This section describes current conditions and recent trends in economic activity within Clallam County and on the Makah Reservation, including Neah Bay. Information presented in this section includes the following:

- Countywide employment, personal income, and tourism statistics
- Commercial shipping information
- Makah tribal employment and personal income statistics
- Local economic conditions related to tourism
- County and tribal income generated by tourism
- Ocean sport and commercial fishing statistics
- Summary of economic effects of media coverage of the 1998, 1999, and 2000 Makah Tribe gray whale hunts

3.6.2 Regulatory Overview

Regulations, statutes, and policies addressing wildlife management and hunting activities in the action area are discussed in other subsections of this section (Subsection 3.3.2, Regulatory Overview (Marine Habitat and Species), Subsection 3.4.2, Regulatory Overview (ENP Gray Whale), Subsection 3.5.2, Regulatory Overview (Other Wildlife Species).

3.6.3 Existing Conditions

3.6.3.1 Countywide Conditions (Clallam County)

3.6.3.1.1 Employment, Unemployment, and Labor Force

Over the past 20 years, the economy in Clallam County has experienced slow but steady growth, shaped in part by a vibrant port district in the county's major coastal city of Port Angeles

(Vleming 2022). Immigration has also continued to rise as many retirees are attracted to Sequim's "sunbelt" climate. The service sector has been experiencing growth over the past decade, and in 2021 accounted for almost 90 percent of all non-farm employment (Vleming 2022). Top employers in the county include two prisons, a hospital, and a school district. Following the popularity of the *Twilight* books and movies, the city of Forks continues to be a tourism destination (Vleming 2022). The economy of Clallam County has historically been resource-based, with an emphasis on forest products, although new industries have moved into the county in the past decade, increasing overall employment. There has also been recent growth in construction and manufacturing sectors (Vleming 2022).

As of November 2022, government jobs made up almost one third of jobs countywide, while the largest proportion of private sector jobs in the county is the service industry (Washington State Employment Security Department 2023a). Retail trade currently accounts for approximately 21 percent of private-sector jobs countywide, with leisure and hospitality accounting for another 19 percent. While historically much of the economy of the county was dominated by jobs in forestry and wood products, as of 2022 only approximately 7 percent of the jobs in the county are in the mining, logging, and construction industries combined (Washington State Employment Security Department 2023a).

In the 10 years from 2012 through 2021, annual average wage in Clallam County was stagnant from 2012 to 2014, then began to steadily increase, with the fastest gains seen from 2018 into 2020. From 2012 through 2015 total employment also held relatively steady, fluctuating between 22,140 and 22,450 jobs, followed by steady growth leading to approximately 23,530 jobs by 2019 (Washington State Employment Security Department 2023b). In 2020, as in communities across the United States the local economy in Clallam County began to shrink as a result of the COVID-19 pandemic and related closure of the Canadian border (Vleming 2022). Most of the job losses occurred in service industries, where almost 70 percent of the 1,350 jobs added between 2012 and 2019 were wiped out in 2020, although by the end of 2021 had already rebounded to levels closer to their pre-pandemic levels (Washington State Employment Security Department 2023b). Employment growth also was relatively stable in the government sector, which added 780 new jobs between 2012 and 2019, only lost 280 of these jobs between 2019 and 2020, and was able to recover 200 of them in 2021. The other sectors with steady job growth in the last decade were professional and business services, with 270 additional jobs, and education and health services, with 110 additional jobs, neither of which lost jobs between 2019 and 2020. Retail trade managed to maintain marginal growth, adding 100 jobs from 2012 to 2021, and leisure and hospitality has

overall gained 140 additional jobs between 2012 and 2021 although this is only a third of the jobs that had been gained by 2019. There were 210 more mining, logging, and construction jobs in 2021 than in 2012, although manufacturing jobs fell throughout the decade, with 520 fewer jobs by 2021 (Washington State Employment Security Department 2023b).

In 2022, an average of 24,640 wage and salary workers were employed in Clallam County. Goods-producing industries, including those involved in natural resources, mining, construction, and manufacturing, accounted for 11 percent of countywide employment (Washington State Employment Security Department 2023b). This proportion is similar to the statewide pattern, where these industries accounted for 14 percent of non-farm jobs at the end of 2022 (Bureau of Labor Statistics 2023). Government employment generated 32 percent of the county's jobs, compared to 16 percent statewide, in 2022. Trade, transportation, warehousing, and utility industries accounted for 17 percent of both Clallam County and statewide wage and salary jobs, whereas the service sector (financial, professional and business services, education and health services, and leisure and hospitality) generated only 35 percent of countywide employment opportunities, compared to 52 percent statewide. Leisure and hospitality jobs actually made up 13 percent of Clallam County's nonfarm jobs in 2022, compared to 9 percent statewide, so this difference in the local service sector impact is due to the relatively smaller contribution of other service types (Bureau of Labor Statistics 2023; Washington State Employment Security Department 2023a).

In addition to wage and salary employment, employment related to business ownership and self-employment is important to the economy of Clallam County. For example, in 2021, proprietors' employment produced 9,164 jobs in addition to contributing to countywide wages and salaries (Bureau of Economic Analysis 2023).

Clallam County's resident civilian labor force averaged 29,275 persons in 2021, reflecting labor force growth of 4 percent since 2012, which is still a decrease from the peak of 30,374 in 2009 (Washington State Employment Security Department 2023b). Unemployment in the county steadily decreased from 10.5 percent in 2012 to 6.5 percent in 2021, despite a short-lived spike when unemployment jumped up to 10.2 percent in 2020 (Washington State Employment Security Department 2023b). Growth in the employment of Clallam County's residents therefore roughly kept pace with growth of the county's resident labor force between 2012 and 2021. However, Clallam County unemployment is still lagging behind the statewide unemployment rates over the same period, which decreased from 8.1 percent to 5.2 percent (Washington State Employment Security Department 2023b, Bureau of Economic Analysis 2023).

3.6.3.1.2 Personal Income

Personal income is generally seen as a key indicator of a region's economic vitality. Personal income, as presented here, captures all forms of income: wages, salaries, government transfer payments, retirement income, farm income, self-employment income, proprietors' income, interest, dividends, and rent, but it does not include contributions toward social insurance. Social insurance payments are those made for certain government programs, including health, disability, unemployment, retirement, life insurance, and workers' compensation insurance programs. Nominal (i.e., not adjusted for inflation) total personal income for Clallam County increased from $2.6 billion in 2011 to $3.9 billion in 2020 (the most recent year for which data are available) (Table 3-20). The increase in personal income between 2011 and 2020 equates to an average annual growth rate of 4.5 percent, lower than the state's average annual growth of 6.3 percent for the same period (Washington State Employment Security Department 2023b, Bureau of Economic Analysis 2023).

Per capita income, which relates an area's total income to its population level, provides an indicator of the economic well-being of the residents of an area. In 2020, per capita income in Clallam County was $49,718, less than the state ($67,126), and the nation's ($59,510) per capita income (Vleming 2022, Bureau of Economic Analysis 2023b). Between 2011 and 2020, nominal per capita income in Clallam County increased by 36 percent (Table 3-20). In 2020, the median household income in the county was $55,090, also behind the state's ($77,006) and the nation's ($64,994), and 13.3 percent of the population was living below the poverty level, higher than the statewide and national rates, although the percentages are not directly comparable (Vleming 2022).

Table 3-20. Population and personal income in Clallam County in 2011 and 2020.

Category	2011	2020	Percent change 2011-2020
Population	71,778	78,067	8.8
Total personal income ($ billion)	2.62	3.88	48.1
Per capita income	36,551	49,718	36.0

3.6.3.1.3 Tourism

Tourism is an important component of Clallam County's economy. The rugged, pristine environment and variety of habitats found along the Olympic Coast and the Strait of Juan de Fuca

provide recreational opportunities for both residents and tourists. Much of the land in Clallam County, including a large segment of its Pacific coastline, is within the Olympic National Park and Olympic National Forest. Olympic National Park attracted an average of 2.8 million recreation visitors per year between 2018 and 2022, although numbers have yet to return to their pre-pandemic peak of 3.2 million visitors in 2019 (National Park Service 2023). This tourism also generates visitation to Clallam County, including visitor centers in Port Angeles, Forks, Sequim, and Neah Bay. The OCNMS, which provides opportunities for wildlife viewing, also attracts visitors to the county's outer coastline. Additional information concerning Olympic National Park and the OCNMS is presented in Subsection 3.12.3.2, Vantage Points and Visual Opportunities in the Action Area.

Tourism and recreation is a relatively large industry in Clallam County and makes up 84 percent of the county's ocean economy (which also includes living resource, marine construction, ship building, marine transportation, and offshore mineral extraction sectors), as compared to 54 percent of the statewide ocean economy (NOS 2023). According to a recent study of travel-related economic impacts, visitors spent $300.7 million at destinations in Clallam County in 2018 (Table 3-21), generating $21.9 million in local taxes and supporting 4,260 local jobs (Table 3-22). Non-local visitors to Olympic National Park alone generated $265 million in visitor spending, supporting an estimated 2,970 jobs with $131 million in associated labor income, and visitors to State Parks in Clallam County spent an additional $2.5 million, generating $128 thousand in State and local tax revenue and supporting 20 jobs (Table 3-23). Spending occurs in several sectors of the county's economy but is greatest in the food and beverage services sector (36 percent of total visitor spending) and accommodations sector (21 percent). The local transportation, arts/entertainment/recreation, and retail sales sectors received approximately 8 percent, 12 percent, and 13 percent of visitor spending in 2018, respectively (Table 3-21).

Table 3-21. Travel Spending in Clallam County in 2018.

Commodity Purchased	Travel Spending ($ millions)	Percent of Total Travel Spending (%)	Change from Prior Year (%)
Accommodations	62.5	21	+7.0%
Food and beverage services	108.1	36	+9.2%
Food stores	30.8	10	+3.4%
Local transportation and fuel	25.6	9	+13.3%
Arts, entertainment, and recreation	36.0	12	+6.2%
Retail sales	37.7	13	+4.7%
TOTAL SPENDING	**300.7**	**100**	**+7.5%**

Source: Olympic Peninsula Tourism Commission (2023a). Visitor spending impacts in Clallam County (2018).

Travel-related spending by visitors to Clallam County generates earnings and employment in visitor-serving industries. Earnings generated by travel spending totaled an estimated $101.5 million in 2018 (Table 3-22). Employment generated by travel-related spending in Clallam County supported a total of an estimated 4,260 jobs in 2018 (Table 3-22), accounting for 27 percent of Clallam County's private sector jobs and 18 percent of all jobs in that same year (Washington State Employment Security Department 2023b).

Table 3-22. Estimated travel-related economic impacts in Clallam County in 2018.

Impact Source	Development Generated
Tourism Supported County Jobs	4,260
Tourism Supported County Earnings	$101.5 million
Local Tax Receipts from Visitor Spending	$6.5 million
State Tax Receipts from Visitor Spending	$15.4 million

Source: Olympic Peninsula Tourism Commission (2023a). Visitor spending impacts in Clallam county (2018).

Table 3-23. Nonlocal spending by visitors to State and National Parks in Clallam County.

Park	Year (most recent data)	Total Annual Expenditures	Jobs Supported
Olympic National Park	2018	$265,000,000	2,970
State Parks	2015	$2,530,000	20

Source: Trust for Public Land (2021).

Visitors to Clallam County as well as local residents participate in an array of sightseeing and recreational activities (The Trust for Public Land 2021). General sightseeing, hiking, wildlife viewing, and visiting historical and cultural sites are among the most popular activities of visitors to the county. In addition to hiking, other popular recreational activities include biking, mountaineering, snow sports, kayaking, tidepooling, diving, boating and water sports, and fishing (Olympic Peninsula Tourism Commission 2023b). Local residents in the North Olympic Peninsula also engage in outdoor recreational activities at higher rates compared to the U.S. average, particularly biking, boating, fishing, hunting, backpacking, hiking, and canoeing or kayaking (Trust for Public Land 2021). This generates additional revenue for the local economy from resident spending on sports, recreation, and equipment (Table 3-24). In addition, households in the region spend $26.1 million annually on recreational vehicles and fees (including boats) (Trust for Public Land 2021). The commercial value of whale-watching activities specifically is described further in Subsection 3.6.3.3.2, below.

Table 3-24. Estimated annual household spending on sport, recreation, and related equipment in the North Olympic Peninsula.

Spending Category	Average amount spent per household	Total Spending (Millions)
Sports, recreation, and exercise equipment	$214.00	$33.1
Bicycles	$30.10	$4.7
Camping equipment	$19.40	$3.0
Hunting and fishing equipment	$71.20	$11.0
Winter sports equipment	$5.62	$0.9
Water sports equipment	$8.22	$1.3

Source: Trust for Public Land (2021). Amounts are in nominal 2020 dollars.

3.6.3.1.4 Commercial Shipping

Next to fishing, the predominant use of waters off the Olympic Coast is commodities transportation to and from port facilities in Puget Sound. In 2013, the U.S. Customs District of Seattle (which includes all ports in Puget Sound, as well as some border crossings along the Canadian border) handled more than $90 billion worth of international trade (Maritime Administration 2023). Included in the commercial shipping traffic are tug boats with barges carrying hydrocarbon products along the coast. The entrance to the Strait of Juan de Fuca is highly congested by oil tankers, freighters, tugs and barges, and fishing vessels (Ecology 2021b). Management of commercial vessel traffic near the action area and marine vessel traffic regulations adopted during the Makah Tribe's previous whale hunt are discussed in Section 3.13, Transportation. Similarly, data on transits into Washington State waters through the Strait of Juan de Fuca by large cargo and passenger vessels, tank ships, barges, and commercial fishing vessels are presented and discussed in Section 3.13, Transportation.

Commercial shipping routes in the Strait of Juan de Fuca and nearby waters, including Haro Strait, Boundary Pass, Rosario Strait, and the Strait of Georgia, are managed jointly by the United States and Canadian Coast Guards, primarily through the Cooperative Traffic System. This system allows for management of vessel traffic in a waterway segment without regard to the international boundary that separates the waters of the United States and Canada. A vessel separation scheme, similar to a divider median on a highway, is used to maintain a safe distance between opposing vessel traffic (Ecology 2021a).

The Strait of Juan de Fuca traffic separation scheme encompasses five sets of traffic lanes, including the western and southwestern approaches to and from the Pacific Ocean, the western lanes in the Strait of Juan de Fuca, the southern lanes to Port Angeles, and the northern lanes to

Victoria. Each set of lanes consists of inbound and outbound traffic lanes with separation zones. The traffic lanes encompassed by the Strait of Juan de Fuca traffic separation scheme generally run through the center of the Strait of Juan de Fuca, near the boundary line separating the waters of the United States and Canada (Ecology 2021a). The southern boundary of the traffic separation scheme generally lies about 4 nautical miles (7.4 km) offshore of Clallam County along the Strait of Juan de Fuca and extends further away from the coast as it leaves the Strait of Juan de Fuca and enters ocean waters. The Makah Tribe's U&A (Figure 3-1) overlaps the traffic separation scheme near the international boundary line in the Strait of Juan de Fuca and encompasses the commercial traffic lanes that provide a southwestern approach to and from the Pacific Ocean near the mouth of the Strait.

Commercial traffic largely honors the OCNMS area to be avoided (Figure 3-1), discussed in more detail in Subsection 3.1.1.1.3, Current Issues (OCNMS), and Section 3.13, Transportation. The Coast Guard RNA, which was established to enforce vessel activities near any Makah whale hunt, falls within the area to be avoided, except for the portion of the RNA that wraps around Cape Flattery and Tatoosh Island (Figure 3-1). The commercial shipping traffic lanes appear to avoid the RNA, indicating that most commercial traffic avoids this area.

3.6.3.2 Local Conditions on the Makah Reservation, Including Neah Bay

Demographic data presented in the Employment and Personal Income parts of this subsection differ from employment and personal income data that will be presented in Section 3.7, Environmental Justice. The data in this subsection apply to all (non-native and Native American) residents of the Makah Reservation, whereas the data presented in the Environmental Justice subsection apply only to Native American residents of the Makah Reservation; therefore, the data do not match.

3.6.3.2.1 General Description of the Local Economy

The Makah Reservation, which includes the community of Neah Bay, is extremely isolated from other communities within Clallam County and the Olympic Peninsula. The reservation has been accessible by road only since 1931, and Neah Bay is a 75-mile drive from the closest commercial center in Port Angeles (Sepez 2001; NPAIHB 2023). The economy in the coastal region that includes the Makah Reservation is inextricably linked to its natural resources, based primarily on seafood, timber harvesting, pulp and paper production, and tourism (Vleming 2022). Neah Bay, the Makah Reservation's central town, is primarily a commercial fishing and timber community, as well as a tourist and sport fishing destination (Neah Bay Chamber of Commerce 2023a).

Similar to other locations on the Olympic Peninsula that depend on resource-based industries, the Makah Reservation and Neah Bay have experienced economic difficulties in recent decades as demand for goods-producing products have decreased (Vleming 2022). The remote location of the reservation further reduces the value of already relatively low per capita income (see Section 3.6.3.2.3 Personal Income, below) due to the additional cost of transporting food and supplies to the area (Renker 2018). In order to meet the needs of its people, the Makah Tribe has made a commitment to diversifying and expanding its access to and use of traditional resources. Among these endeavors was a program that facilitated the sharing and enhancement of tribal members' knowledge and skills in management of non-timber forest resources, such as floral supplies and materials for basketry (Renker 2018). The Tribe has also diversified its marine fisheries over the past two decades, particularly in the development of its trawl and longline fisheries, focus on increasing the shellfish resource (specifically aquaculture of geoduck clams), and opportunities for small vessels to engage in Dungeness crab and Lingcod fisheries in seasons when other tribal fishing opportunities are limited. Despite these successes, fluctuations in the reservation's natural resources, commercial fishing, tourism, and sport fishing continue to present challenges to the Tribe's ability to ensure reliable incomes and subsistence sources for its members (Renker 2018).

Most reservation residents live in Neah Bay, the location of the public school, post office, general store, health clinic, and other services (Renker 2018). Commercial activity on the Makah Reservation includes the businesses shown in Table 3-25, which mainly are located in Neah Bay. Tribal artisans also produce carvings, jewelry, and silk screen designs for sale in local shops and regional galleries (Sepez 2001; Neah Bay Chamber of Commerce 2023a). All businesses on the reservation are owned by tribal members or leased by the Tribe to non-tribal members (B. Denney, Makah Community Planning and Economic Development, pers. comm., July 2012).

3.6.3.2.2 Employment

In 2021, the estimated labor force residing on the Makah Reservation was 691 persons of the 1,140 residents ages 16 years and older. Of the total population (1,519), 1,139 identified as American Indian or Alaska Native (primarily Makah tribal members), representing 75 percent of the reservation's population (United States Census Bureau 2023a). Unemployment trends and industrial employment data specifically for the Native American population residing on the Makah Reservation are presented and discussed in Section 3.7, Environmental Justice.

According to the 2017 to 2021 American Community Survey estimates, 587 of the 691 Makah Reservation residents in the labor force were employed in 2020. Of the 587 Makah Reservation residents with jobs in 2020, 68 percent were employed by government entities, 12 percent were

self-employed, and 20 percent were employed by private businesses (United States Census Bureau 2023). This employment distribution points to the importance of the government sector to the economy of the Makah Reservation and Neah Bay. In addition to state and federal employment, the Makah Tribe, which is the largest employer on the reservation, employs approximately 300 people (K. Vogel, Makah Tribe, Human Resources Director, pers. comm., April 21, 2023). Management and professional occupations, many probably related to government employment, accounted for 39 percent of the jobs held by reservation residents in 2021 (Table 3-26). Service, sales, and office occupations together accounted for an additional 32 percent of total jobs. Construction, maintenance, and occupations related to the area's natural resources provided jobs for 16 percent of the reservation's employed labor force (Table 3-26). The United States Census data may undercount the reservation's employment associated with fishing occupations. According to the Makah Tribe, commercial vessels owned and operated by Makah tribal members generated approximately 515 jobs in 2011, including vessel skippers, deckhands, and river set-net fishermen (J. Johnson, Makah Fisheries Management Data Manager, pers. comm., July 11, 2012). The number of participants in treaty commercial fisheries is variable by year due to factors such as weather, catch limits, market valuation of fish and shellfish, and regulations. Other employers on the Makah Reservation include the Indian Health Service medical center, the wellness center, and dental clinics, with 22 employees, and the Cape Flattery Public Schools, with 113 employees between the Neah Bay and Clallam Bay schools (Norman et al. 2007; Office of Superintendent of Public Instruction 2023).

3.6.3.2.3 Personal Income

Personal income levels of Makah Reservation residents (non-native and Native American together) lag behind those of residents throughout Clallam County. According to the U.S Census Bureau (2023a and 2023b), the median income of reservation households was $47,167 in 2021, representing only 79 percent of the median countywide household income of $60,044. In addition, 21 percent of all residents had income that was below the poverty level in the prior 12 months in 2021, a much higher rate than the 12 percent at or below the poverty level in 2022 across Clallam County (U.S. Census Bureau 2023a and 2023b).

Because Neah Bay is isolated, most of the earnings of local residents come from the wage and salary payments of local businesses. Based on an informal survey of businesses in Neah Bay, local businesses generate an estimated annual total payroll of about $21 million (Arnold 2005).

3.6.3.2.4 Contribution of Tourism to the Local Economy

Tourism is one of the key elements of the economy of Neah Bay and the Makah Reservation. Visitors are attracted to Neah Bay and the reservation by several activities associated with the area's cultural, scenic, and recreational offerings.

In the village of Neah Bay, the Makah Cultural and Research Center houses the Makah Museum, which includes permanent exhibits featuring artifacts from the Ozette archeological site (Ozette was an ancient Makah village discovered in 1970 on the Pacific Coast side of the reservation). The museum, which houses the nation's largest collection of Native American artifacts, is connected to a gift shop that offers visitors carvings, basketry, and jewelry made by Makah artists. The Makah Cultural and Research Center also houses the Makah language program, which is designed to preserve and teach the Makah language.

Neah Bay also offers visitors opportunities for sport fishing charters and guided tours. Several visitor-dependent businesses are located in Neah Bay, including businesses providing accommodations, restaurants, several retail shops providing fuel and supplies, and sport fishing charter businesses (some of which may offer whale watching if requested; Table 3-25). Many people travel to the coast to watch the annual migration of gray whales. Most whale-watching on and near the Makah Reservation is from land-based locations, with few businesses offering

whale-watching tours or charters. For more information on whale-watching tourism see Section 3.6.3.3.2, Commercial Value of Whales, below.

Several other tourist and recreation activities are available elsewhere on the Makah Reservation, including vehicle sightseeing tours along forested State Route 113 and the irregular Strait of Juan de Fuca coastline accessed by State Route 112. Beach activities are available to reservation visitors at sandy beaches near Neah Bay and along Hobuck Beach Road on the Pacific Ocean coast side of the reservation. Camping is available at Hobuck Beach, as well as in Neah Bay, and Shi Shi Beach is a popular destination for campers during summer months (Neah Bay Chamber of Commerce 2023b; Table 3-25).

Hiking is a popular activity for recreationists visiting the reservation. Popular trails include the 0.75-mile (1.2-km) Cape Flattery Trail and the 3.3-mile (5.3-km) Shi Shi Trail. The Cape Flattery Trail, with observation decks for viewing Tatoosh Island, sea stacks and sea caves, and the Pacific Ocean, is popular with ecotourists and those interested in wildlife viewing opportunities. Wildlife viewing also is available at Flattery Rocks National Wildlife Refuge and the Olympic Coast National Marine Sanctuary. Additionally, the public can view migrating salmon at the Makah National Fish Hatchery, located on the Tsoo-Yess River on the west side of the reservation (Neah Bay Chamber of Commerce 2023b).

Based on estimates of the number of people who may come to the area for various tourist activities (including fishing, surfing, hiking, and visiting museums), Parametrix (2006) generated an estimate of 25,000 to 40,000 annual visitors to Makah lands. Specific activities and sources of revenue included:

- the Makah Cultural and Research Center, which includes the Makah Museum, accommodated an annual average of roughly 14,000 non-Makah visitors (J. Bowechop, Makah Cultural and Research Center Director, pers. comm., April 20, 2021).
- Between March 14, 2022 and April 1, 2023, the Tribe sold 24,600 recreational use permits (J. Cooke, Makah Tribe, pers. comm., April 21, 2023). Sales of permits peak during summer months and are lowest during the winter. Recreational permits are required for non-tribal persons on the reservation. Permits are sold on a per vehicle basis and are good for a calendar year; this number of permits does not capture the total number of non-tribal persons visiting the reservation in a calendar year, nor does it capture the length of a visit and the number of visits an individual may make to the reservation under a single permit.

- In 2022, the Makah Tribe sold 25 recreational fishing permits (Makah Tribe 2022b). This is down from 2006-2011 when the Makah Tribe sold an average of 363 recreational fishing permits per year, generating an annual average of $7,261 in revenue. The number of permits sold ranged from 496 in 2009 to 181 in 2010 (J. Johnson, Makah Fisheries Management Data Manager, pers. comm., July 11, 2012). The permits, which are sold on an individual basis, allow visitors to fish on rivers within the reservation.

Visitation trends over the past five years are unlikely to be indicative of future tourist travel and activity. From March 2020 through 2022, tribal leaders decided to close the reservation to outsiders for two years to protect the health of their community during the COVID-19 pandemic (Pailthorp 2022). Given the rate of recovery of the Clallam County economy and tourism sector, it is likely visitor numbers to the reservation will also rebound quickly in the coming years.

Persons visiting the Makah Reservation for tourism and recreational purposes generate revenues for businesses in Neah Bay, all of which are owned by tribal members or leased by the Tribe to non-tribal members (B. Denney, Makah Community Planning and Economic Development Planner, pers. comm., July 11, 2012). The amount of revenues annually generated by reservation tourism and recreation, as well as the number of jobs and amount of personal income that depend on visitor spending, is not known. According to the U.S. Census, 56 reservation residents were employed in 2021 in the retail trade sector and the arts, entertainment, recreation, accommodation, and food services sector, two sectors that depend directly on tourism (Table 3-27). These jobs account for approximately 10 percent of the employment in the local area (Table 3-27). Many other local jobs likely are either directly or indirectly supported by tourist spending.

3.6.3.2.5 Contribution of Ocean Sport Fishing to the Local Economy

The diversity and abundance of fish species along the coast are important recreational and commercial resources. Salmon and groundfish (including halibut) fisheries are the primary recreational fisheries within the action area, including the Makah U&A, the OCNMS area to be avoided, and the Coast Guard RNA (Figure 3-1). Recreational fishing for groundfish is concentrated primarily seaward of the entrance to the Strait of Juan de Fuca. The ocean recreational fishery for salmon, which operates out of both Neah Bay and La Push, occurs offshore (e.g., Swiftsure Bank) and in the protected waters of the Strait of Juan de Fuca.

Ocean sport fishing seasons vary according to species, with seasons adjusted from year to year based on fishery management considerations. The recreational salmon fishery from Cape Alava (near Ozette) north to the United States/Canada border and for the Strait of Juan de Fuca near Neah Bay is generally open from early July until early or mid-September each year, and in 2022

the Neah Bay subarea was open from June 18th through September 30th (PFMC 2022g). The recreational groundfish fishery is generally open year-round, although the season is limited for certain species. For example, in 2023, the recreational season for lingcod north of Cape Alava is set to be open from mid-March through mid-October (WDFW 2023a), while the halibut season is set to be open for a total of 19 days in May and June (WDFW 2023b). Periodic openings and closings for specific species may occur during the normal fishing season period.

Several fishing derbies and tournaments also draw visitors to Clallam County's sport fisheries each year. Annual derbies and tournaments in Clallam County include the Olympic Peninsula Salmon Derby in February, the Port Angeles Halibut Derby over Memorial Day weekend in May, the Sekiu Halibut Derby in June, the Sekiu "No Fin, You Win" Salmon Derby in mid-September, and the La Push Last Chance Salmon Derby in late September or early October.

Sport fishing facilities located in Neah Bay include the Makah Marina, which is managed by the Makah Tribal Council. The marina provides permanent moorage slips for about 200 commercial and sport fishing vessels and pleasure craft. The marina also provides utility hookups, restrooms and showers, and a pump-out facility for boats. Boat launching ramps and trailer parking facilities also are available at Big Salmon Resort in Neah Bay (Makah Tribal Council 2023).

Between 2016 and 2020, the annual number of recreational salmon angler trips in Marine Area 4, offshore from Neah Bay and Cape Flattery, ranged from 6,885 trips in 2020 to 10,791 trips in 2017 (Kraig and Scalici 2019 and 2022). The annual number of angler trips targeting groundfish and halibut in the same area are not similarly reported in annual WDFW catch reports, although landings from sport fishing over the same period suggests angler trips continued at roughly the same magnitude over the past five years, with the exception of 2020 (Table 3-28). This information on landings suggests that demand in the area has remained, and recreational fishing remains a viable source of income for communities on the Makah Reservation. Due to pandemic-related Neah Bay port closures in 2020 and 2021 there were no charter trips originating from Neah Bay in those years, although salmon angler effort ranged from 8,700-10,700 trips and bottomfish effort ranged from 17,500-22,600 trips leaving Neah Bay each year from 2017-2019 (Pacific Fisheries Management Council 2022). Following the lifting of port closures in 2022 and continued landings in the area, angler trips appear likely to resume at levels approaching those of 2019, following trends in the rest of the economy.

As described above, there was no recreational fishing based out of Neah Bay in 2020 and 2021, however expenditures associated with recreational fishing from 2017-2019 indicate it is and will continue to be an important source of revenue for the community. Over this period, expenditures

associated with recreational ocean salmon fishing generated between $601,000 and $721,000 of personal income (in 2021 dollars) in Neah Bay each year (Pacific Fisheries Management Council 2022). No directly comparable information is available for local spending associated with the recreational groundfish fishery. Estimates presented in the 2008 Makah Whale Hunt DEIS indicate that spending associated with the recreational groundfish fishery was of a similar magnitude to spending associated with the recreational salmon fishery.

Table 3-28. Sport fishing catch of select species near Neah Bay 2016 to 2020.

Catch Reported (Areas including Marine Area 4)	2016-2017	2017-2018	2018-2019	2019-2020	2020-2021*
Total salmon	3,415	11,732	8,225	10,930	5,115
Halibut	6,003	5,683	6,365	8,011	3,328
Black rockfish	63,708	56,716	59,138	56,707	18,946
Lingcod	13,813	13,650	10,076	13,652	7,799
Spot shrimp (lbs)	1,300	1,300	1,300	1,300	1,300
Dungeness crab (lbs)	1,420	1,612	782	873	1,173

*Demand for and availability of recreational fishing charters likely affected by COVID-19 restrictions

3.6.3.2.6 Contribution of Ocean Commercial Fishing to the Local Economy

High levels of commercial fishing occur throughout the Strait of Juan de Fuca and near the approach to the Strait over Swiftsure Bank. Fish harvested by commercial vessels in the North Puget Sound Ports include five species of salmon, bottom fish, and shellfish (Dungeness crab and pink shrimp). Salmon fisheries, particularly the ocean troll fisheries for Chinook salmon and coho salmon, are managed to safeguard against over-harvest of the least viable individual stocks. Salmon harvest restrictions have severely constrained harvest levels in some years.

Commercial landings for various species vary widely, although overall remain a critical source of revenue for Washington State. Based on data derived from the Pacific Fisheries Information Network (PacFIN) commercial catch database, the value of commercial fish landings in the North Puget Sound Port Group (which includes the Port of Neah Bay) between 2016 and 2020 ranged from $42.5 to $69.4 million annually (Table 3-29). During that period, crab fisheries were the largest contributor to total revenue, although the landings of salmon, halibut, sablefish, shrimp, and sea cucumbers also contributed significant portions of the total revenue in the port group (Table 3-29).

Table 3-29. Landings revenue from commercial fishing in the North Puget Sound Port Group from key species groups (in nominal dollars).

North Puget Sound Port Group	2016	2017	2018	2019	2020
Key Species					
Albacore tuna	585,600	153,693	0	118,958	376,231
Clams	6,875,235	0	0	0	0
Crab	33,863,829	37,772,359	30,512,017	30,261,918	28,072,582
Flatfish (sole & flounder)	1,253,583	1,474,283	1,566,631	1,268,661	148,026
Lingcod	217,419	443,516	233,536	84,347	50,969
Pacific halibut	2,440,274	2,239,528	1,572,996	2,071,974	1,584,634
Rockfish	415,309	439,512	299,243	594,753	34,131
Sablefish	4,231,733	5,545,124	4,113,262	3,288,775	1,859,182
Salmon	6,897,426	7,735,314	6,737,202	4,187,636	2,094,667
Sea cucumbers	2,254,045	2,064,079	1,011,717	1,230,375	608,395
Shrimp & prawns	3,060,521	2,997,718	2,485,528	3,100,296	3,292,722
Total	**64,609,123**	**69,416,358**	**54,435,434**	**53,843,289**	**42,532,508**

Note: Not all species included in the total are listed. Also, because virtually no whiting is landed and sold at the ports but is instead processed offshore, the value of this fishery is not reflected in catch data reported by port group.
Source: PSMFC 2023.

Commercial ocean fishing seasons vary according to species, with seasons adjusted from year to year. The non-tribal commercial salmon troll fishery from Cape Falcon (near the Oregon/Washington border) north to the United States/Canada border generally is open from early May until late June for all salmon species except coho salmon. During some years, the fishery is open for all salmon species from early July until early or mid-September. For tribal commercial fishing, including the Makah Tribe, salmon fishing is generally open from early May until mid- to late June, and then again from early July until mid-September. Commercial groundfishing is generally open year-round for some species, with seasonal limits imposed on certain species. During the course of any year, periodic openings and closings for specific species may occur during the season (PFMC 2022f).

The tribes are co-managers of the fisheries resources and are involved in management plan development, monitoring, licensing, and enforcement. Based on the Boldt decision (*United States v. State of Washington* 1974), the tribes and non-tribal fishers are apportioned salmon and steelhead by region of origin. The tribes also have recognized treaty rights to other species. Since 1986, the tribes have received a direct halibut allocation from the International Pacific Halibut Commission. Since approximately 1994, the Washington State coastal tribes have received an allocation of black cod (sablefish) from the PFMC. That tribal allocation of both halibut and black cod subsequently is divided among the tribes by intertribal agreement. Pacific whiting,

rockfish, and groundfish tribal harvest allocations are established on a year-to-year basis by the PFMC. Refer to Subsection 3.1.2.1, Makah Tribal Departments, Agencies and Commissions, and Subsection 3.1.2.1.1, Makah Fisheries Management Department, for more information on tribal fisheries management programs.

Commercial fishing is one of the mainstays of the Makah Reservation economy. The Makah Tribe conducts a marine gillnet fishery along the shore near Cape Flattery and in the Strait of Juan de Fuca for Chinook salmon and sockeye salmon. The Makah also participate in a variety of groundfish fisheries. Rockfish, sablefish, Pacific halibut, and whiting are the targeted species and are taken by trawl and longline gear. These fisheries occur year-round, and are centered off the north coast of the Olympic Peninsula.

As of 2011, 188 commercial vessels, all operated by Makah tribal members, were based out of Neah Bay. Tribal employment related to commercial fishing amounts to approximately 515 jobs (Subsection 3.6.3.2.2, Employment).

The Makah Tribe also participates in the Pacific whiting fishery. Between 2018 and 2022, the allocation to the Tribe ranged from a low of 64,645 metric tons in 2021 to a high of 70,463 metric tons in 2022, although in some years unharvested tribal amounts are later reapportioned to non-tribal fleets (86 FR 62804 and 87 FR 33442). This fishery usually opens around the middle of May and closes at the end of December. Most of the whiting caught in the tribal fishery is processed at sea on a processing vessel. Smaller portions of the allocation are delivered to a shoreside processing facility in Westport, Washington.

3.6.3.3 Gray Whale Economic Values

3.6.3.3.1 Summary of Economic Effects of the Makah Gray Whale Hunts

No quantitative information is available concerning the economic effects of the Makah Tribe's practice whale hunt exercises in late 1998, or their whale hunting in the spring of 1999 and in 2000, but anecdotal information from media coverage of the hunts on protest and media activity and subsequent tourism-related effects provides some indication of the impacts on the local economy.

As described in more detail in Section 3.13, Transportation, news accounts indicate that protests and media coverage of the practice whale hunt exercises in 1998 and the hunts in 1999 and 2000 temporarily generated an increase in the number of people seeking accommodations and services in the communities of Neah Bay, Clallam Bay, and Sekiu. The change in local economic activity during these periods is, however, difficult to assess based on available information. For example,

based on one account (Sullivan 2000), rooms at the Cape Motel and all other motels in Neah Bay were booked by television stations and newspaper staff during the attempted whale hunts in October 1998. In an article published in the *Seattle Times* on October 8, 1998 (Mapes 1998a), however, it was noted that, "One of the biggest surprises of this hunt has been the small turnout of protesters," although the article may have been referring to the demand for accommodations in and near Neah Bay rather than the actual number of protesters near the hunt. According to the article, which noted that protesters were primarily staying in Sekiu, "Campgrounds are empty, and some motels still have vacancies." The same article reported that about 40 media representatives from all over the world were in the Neah Bay area covering the possible whale hunt during October 1998. During the May 1999 whale hunt, which occurred on 4 days of 1 week, the journalists who took up temporary residence on the reservation hired a boat to transport them to the hunting grounds (Sepez 2001). Protesters again arrived in the Neah Bay area during whale hunts in spring 2000 (Oldham 2003). Comparing the spring 1999 and 2000 hunts, the number of protesters decreased from a peak of 50 people during the 1999 whale hunt to a core group of less than 24 people (Welch 2000). Groups of protesters (numbering up to 40 people) staged weekly protests near the Makah Reservation boundary and sometimes temporarily blocked State Route 112, the only paved route to the Makah Reservation, during the 1999 and 2000 hunts (Mapes and Solomon 1999a; U.S. Coast Guard 1999b; Seattle Post-Intelligencer 2000).

In addition to onsite protests, the Makah whale hunts generated calls for boycotts of Makah tribal enterprises and Washington State products by some groups and individuals opposing the hunts. For example, as early as 1997, members of the Sea Shepherd Conservation Society, an opponent of the hunts, reportedly suggested calling for a boycott of tourism on the Olympic peninsula (Westneat 1997). Again, in 1998, it was reported that some activists threatened to organize a boycott of Olympic Peninsula tourism (Simon 1998), although organized boycotts apparently never materialized. In March 1999, an Australian-based animal-rights group called Australians for Animals launched an international boycott of apples produced in Washington State to protest the Makah Tribe's whale hunts, with the group's president claiming that over 1 million people had signed onto the boycott; however, the boycott apparently had no immediate effect on sales of Washington apples (Mapes 1999). Additionally, the Makah Tribe was reportedly listed as the target of a boycott by Co-Op America, an economic action group that teaches individuals how to invest in environmentally responsible ways (Dougan 2001). No information is available to determine whether any of the individual or group calls for boycotts had any effect on Makah tribal enterprises, Olympic Peninsula tourism, or Washington State commerce.

Anecdotal information suggests that any economic effects on tourism may have been minor, as reported in a *Seattle Times* article in August 1999 (Associated Press 1999). Gordon Bentler, the owner of the Cape Motel in Neah Bay, was quoted in the article as saying, "I've noticed no drop. In fact, I think we're probably up this year over last." Also quoted in the article was Rick Hert, executive director of the North Olympic Peninsula Visitor and Convention Bureau, who indicated that room-tax figures from Clallam County hotels and motels appeared relatively flat during the summer of 1999. Bob Buckingham, manager of the marina in Neah Bay, was quoted as saying, "We haven't seen any sign of that [the hunt] affecting us out here. Our actual marina revenue is up from last year so far. We're getting quite a bit of tourism up here." It is unknown whether businesses experienced a decrease in sales because of negative attitudes toward whaling by whale-watchers or other tourists, but it is possible that some businesses were affected.

3.6.3.3.2 Commercial Value of Whales

In the past, whales were valued worldwide as a commercial resource, primarily to satisfy the global demand for whale oil but also for human and animal foods, fertilizer, leather, and pharmaceuticals (Freeman and Kreuter 1994). Commercial whaling resulted in widespread depletion of many whale species, and governments began to develop regulations and policies to sustain and conserve the whale resource (refer to Subsection 3.4.3.1.3, Population Exploitation, Protection, and Status, for more information about the development of legal protections). Though a moratorium on commercial harvest of gray whales and right whales had been in place since 1937 and was reaffirmed in the 1946 ICRW, commercial harvests of other whale species occurred as late as the 1970s and early 1980s. In December 1971, the United States banned all commercial whaling by U.S. nationals and sought, starting in 1972, an international moratorium on the commercial killing of all whales in the IWC arena (16 USC 916 note, PL 96-60, August 15, 1979). As noted in Subsection 3.12, Aesthetics, Congress found that "whales are a unique marine resource of great aesthetic and scientific interest to mankind" and declared that "the protection and conservation of whales are of particular interest to citizens of the United States" (16 USC 916 note, PL 96-60, August 15, 1979). Congress also found that "marine mammals have proven themselves to be resources of great international significance, aesthetic and recreational as well as economic" (16 USC 1361(6)). The IWC adopted a 5-year commercial whaling moratorium in 1982 and implemented it in 1986. Some commercial whaling does exist today; Norway under an objection to the ICRW's commercial whaling moratorium (see information about Article V.3 objections in Subsection 1.2.4.1.1, Functions and Operating Procedures of the IWC) and Iceland under a reservation to the moratorium. Iceland and Japan conduct scientific whaling under Article VIII of the ICRW, but not for gray whales.

More recently, whales have become a commercial resource for the whale-watching industry, a fast-growing tourist activity in several regions of the world (Freeman and Kreuter 1994, O'Connor et al. 2009, Hoyt and Parsons 2014). In 1994, Kalland reported that participants at a marine mammal conference in 1980 estimated the non-lethal commercial value of cetaceans to be about $100 million dollars, approximately the same value as commercial whaling industries of the day (Kalland 1994). He noted that commercial whaling had largely ceased, and the non-lethal commercial value of whales had increased. About a decade later, Hoyt (2001) reported that whale watching (including vessel-based whale watching and whale-based tourism out of 'dolphinaria,' where some places market swimming with whales) was still on the rise. The number of whale watchers worldwide more than doubled between 1991 and 1998, from 4 to 9 million people per year, and the total expenditures increased from $504 million in 1994 to $1 billion in 1998 (Hoyt 2001). By 2008, participation had increased to 13 million people worldwide, generating total expenditures of $2.1 billion (O'Connor et al. 2009). In the Salish Sea, the number of whale-watching companies remained relatively stable from 2009 to 2019, although the number of active whale watching vessels has doubled in that timeframe (Industrial Economics 2020).

Some people who commented during public scoping for this FEIS expressed their concerns that a gray whale hunt would affect revenues of the local, regional, and west-coast-wide whale-watching industries by causing whales to avoid boats, as whale-watching is among the attractions that draws visitors to Clallam County (Forks Washington Chamber of Commerce 2013; Olympic Peninsula Tourism Commission 2023c). However, there is no evidence to suggest that whales would begin avoiding whale watching vessels as a result of the hunt (see Subsection 3.4.3.5.2, Whale Response to Being Pursued). Furthermore, while some operators in Clallam County advertise whale-watching tours (e.g., Windsong Fishing Charter & Whale Watching), and charters may be available through some sport fishing boat operators, much of the whale-watching in Clallam County is done from land-based locations along its seashore (Olympic Peninsula Tourism Commission 2023c). In Puget Sound, an estimated 230,000 people participated in land-based whale-watching, compared to 70,500 who participated in boat-based whale-watching in 2017. Combined, whale-watching contributes an estimated $113 million annually to Puget Sound's GDP, supports nearly 2,000 jobs and $67 million in wages in the Puget Sound Region, and contributes more than $12 million in state and local taxes (Van Deren et al. 2019).

Whale watching primarily occurs during autumn and spring, corresponding with the annual southern and northern migrations of the gray whale. Poor weather conditions often make viewing difficult during the winter southward migration. During the spring northward migration, land-

based whale-watching opportunities are good from several locations on the Pacific Ocean coast, including Cape Flattery on the Makah Reservation; Shi Shi Bluffs, south of the Makah Reservation; Cape Alava, near the Ozette Indian Reservation; and at La Push, and orcas and gray whales can occasionally be seen along the Strait of Juan de Fuca from Sekiu Overlook, Salt Creek Recreation Area, and Freshwater Bay County Park (Bermant 2010; Olympic Peninsula Tourism Commission 2023c).

Outside of Clallam County, whale-watching is an important tourist activity off Westport, located on Washington's Pacific coastline at Grays Harbor, approximately 80 miles (129 km) south of the Makah U&A. Whale-watching trips originating from Westport occur from March to May when gray whales can be viewed just off the coast during their annual migration to northern feeding grounds. Some of Westport's charter boat businesses offer gray-whale focused whale-watching trips during this period, along with halibut, bottom fish, salmon, and tuna fishing charter trips at various times throughout the year (Westport-Grayland Chamber of Commerce 2023). Other locations in Washington advertising whale watch tours/charters (although often focused on killer whales) include: Anacortes, Bellingham, Friday Harbor, Port Townsend, Seattle, and Vashon Island. (GoNorthwest 2014). Along the Oregon coast, the following ports were identified by the Oregon Coast Visitors Association (2014) as offering charter-boat businesses: Brookings, Charleston, Depoe Bay, Garibaldi, and Newport, and the Oregon State Parks Oregon Whale Watch website also maps several locations along the coast for land-based gray whale-watching (Oregon State Parks 2023). In California, most whale-watching charters appear to be concentrated from Fort Bragg south, but a few charters advertise gray whale trips out of Eureka and Crescent City (Trekaroo 2014). There are also several national parks and monuments and state parks and reserves in California from Mendocino to San Diego identified as locations for prime land-based gray whale watching (Visit California 2023).

Whale watching is also an important tourist activity in the inland waters of Washington State and British Columbia. The peak season for whale watching in this region is usually April through October, with the target species primarily being killer whales. Some operators offer year-round tours as weather permits. Other species targeted include humpback whales, gray whales, and minke whales (Gless and Krieger 2023). The number of active vessels in the U.S. and Canadian commercial whale watching fleets in the boundary waters of Haro Strait increased steadily from 2012-2019 before declining precipitously in 2020, likely due to restrictions associated with the COVID-19 pandemic. Visitorship to Lime Kiln State Park on the west side of San Juan Island—a

popular site for land-based viewing of marine wildlife—followed similar trends during this time period (Frayne 2021).

3.7 Environmental Justice

3.7.1 Introduction

The primary issue of concern addressed in this section is the extent to which the alternatives would disproportionately affect minority and low-income populations. United States Census data from 2020 are used to describe existing conditions for population, employment, personal income, and poverty characteristics of minority and low-income populations in Clallam County, with particular focus on tribal communities within the county. These data form the basis for identifying minority and low-income populations, as well as assessing the relative severity of the impacts of the action alternatives on these communities and economies regarding changes in income, employment, net economic value, and direct and indirect sociological impacts. Unlike Section 3.6, Economics, the information and data provided in this Section focuses on tribal members. Although non-native persons also reside on reservations in Clallam County, we consider the statistics for employment, income, and povery on these reservations to be representative of those for tribal employment, income, and poverty given the high proportion of Native American residents.

3.7.2 Regulatory Overview

Executive Order 12898, Environmental Justice, requires that federal agencies "identify and address the . . . disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations." Based on assessment of the demographic data presented later in this section and preliminary analysis of the type and location of effects potentially resulting from the alternatives, the environmental justice analysis for the alternatives focuses on residents of Native American reservations in Clallam County, the majority of whom are Native Americans.

The EPA Office of Civil Rights and Environmental Justice developed guidance for all federal agencies conducting environmental justice analyses. This environmental justice analysis follows the EPA guidelines. The EPA environmental justice guidelines offer a range of categories to indicate the presence or absence of environmental justice effects (EPA 1998; EPA 2015). Consequently, this indicator-based assessment draws topically from the range of indicator categories EPA (1998) outlined, from information provided in other sections of this environmental impact statement, and from other information relevant to the circumstances of the tribal communities.

3.7.3 Existing Conditions

Existing conditions for the environmental justice analysis are based on information on minority populations in Clallam County. This includes information on demographics, employment, personal income, and poverty characteristics of these populations.

3.7.3.1 Minority Populations

The following subsections provide information on the size and demographic characteristics of minority populations in Clallam County, including Native American populations and the Makah Tribe.

3.7.3.1.1 Clallam County

In 2020, Clallam County's population totaled 77,155 residents (U.S. Census Bureau 2021a), with 41 percent of the population residing in Callam County's three incorporated areas (Port Angeles, Sequim, and Forks). The largest of these is Port Angeles, with 20,120 residents, followed by Sequim (8,125 residents), and Forks (3,335 residents) (Vleming 2022, U.S. Census Bureau 2020).

The population of Clallam County is largely white, with whites accounting for 86.3 percent of the county's residents in 2020 (Table 3-30) (U.S. Census Bureau 2021a). American Indians and Alaska Natives (hereafter referred to as Native Americans) are the only other relatively large racial group in the county. The 4,346 Native Americans residing in Clallam County in 2020 accounted for 5.6 percent of the countywide population. Together, all other racial groups accounted for 19.1 percent of the population. Hispanics, who can be categorized as members of other racial groups for the purposes of the U.S. Census, accounted for 7.4 percent of the county's population in 2020.

Table 3-30. Racial distribution of Clallam County population in 2020.

Race	Number	Percent (%)
White	62,450	80.9
Native American[1]	4,346	5.6
Asian[1]	1,263	1.6
Black[1]	615	0.8
Native Hawaiian and other Pacific Islander[1]	119	0.2
Some other race[1]	1,676	2.2
Two or more races	6,686	8.7
Total	**77,155**	**100.0**
Hispanic or Latino[2]	5,710	7.4

[1] This only includes persons reporting a single race.

[2] For purposes of the United States Census, Hispanics or Latinos may be of any race, thus,they are already included in other applicable race categories in the table.

3.7.3.1.2 County Tribal Demographics

Four Native American reservations are located in Clallam County: the Makah Reservation, encompassing Neah Bay; the Jamestown S'Klallam Reservation and off-reservation trust lands at Blyn near Sequim; the Lower Elwha Reservation and off-reservation trust lands west of Port Angeles; and the Quileute Reservation at La Push. Additionally, the Hoh Tribe maintains a business committee office in Forks (in Clallam County), although the Tribe's reservation is located in Jefferson County near the mouth of the Hoh River. The Quinault Tribe, whose reservation is in Grays Harbor County, also has an administrative office in Forks.

Together, the population of Clallam County's four reservations totaled an estimated 2,782 persons, including an estimated 1,962 persons of Native American ancestry alone, in 2021 (Table 3-31). Non-tribal members also live on reservation properties, including those married to tribal members and those with jobs on the reservation. According to U.S. Census data, an estimated additional 2,384 Native Americans in Clallam County lived outside of reservation and trust land properties in 2021. Among the four reservations in the county, Native American populations ranged from 5 people on the Jamestown S'Klallam Reservation to 1,139 people on the Makah Reservation.

Table 3-31. Population of American Indian reservations and trust lands in Clallam County, estimated for 2017-2021.

Reservation	Total Population	American Indian[2]
Makah	1,519	1,139
Quileute	336	291
Lower Elwha[1]	717	527
Jamestown S'Klallam[1]	210	5
TOTAL	**2,782**	**1,962**

[1] This includes the population on off-reservation trust lands.
[2] This only includes Native Americans reporting one race.
Source: U.S. Census Bureau 2021c

Table 3-32 presents selected demographics for Native Americans and non-Native residents residing on the four reservations in Clallam County. The most notable characteristic of reservation demographics is the youthful nature of their populations. The median age of the populations was estimated to be well below the median age of 50.8 years for all residents in Clallam County in 2021 (U.S. Census Bureau 2021d). The median age of reservation populations ranged from 30.4 years for the Makah Reservation to 31.6 years for the Quileute Reservation (Table 3-32).

Differences also exist in the average household sizes of the reservation populations, which were higher than the countywide averages of 2.25 persons per household in 2021 (U.S. Census Bureau 2021e). Excluding the Jamestown S'Klallam Reservation, average size of renter-occupied units ranged from 2.50 on the Lower Elwha Reservation to 4.68 on the Quileute Reservation. The average size of owner-occupied units ranged from 2.91 on the Quileute Reservation to 3.25 on the Makah Reservation (Table 3-32).

Table 3-32. Selected demographics of Native Americans and non-native residents residing on reservation and trust lands in Clallam County, estimated for 2017-2021.

Category	Makah Reservation[1]	Quileute Reservation[1]	Lower Elwha Reservation and Trust Lands[1]	Jamestown S'Klallam Reservation and Trust Lands[1]
American Indian and Alaska Native (%)	87.6	86.6	73.5	2.3
Male (%)	47.8	48.2	49.4	43.3
Female (%)	52.2	51.8	50.6	56.7
Median age (years)	30.4	31.6	30.9	66.4
Age under 18 years (%)	28.3	33.0	26.1	1.4
Age 65 years and over (%)	11.5	17.6	11.7	71.9
Average size of renter-occupied unit (persons)	2.28	4.68	2.50	2.50
Average size of owner-occupied unit (persons)	3.25	2.91	3.00	1.93
Owner-occupied housing units (%)	73.4	59.8	47.3	98.1
Renter-occupied housing units (%)	26.6	40.2	52.7	1.9

[1] Data represents Native Americans reporting only one race and non-native residents living on the reservations .
Source: U.S. Census Bureau 2021c

3.7.3.1.3 Makah Tribe

The U.S. Census Bureau (2021c) reported that an estimated 1,139 Native Americans lived on the Makah Reservation in 2021, reflecting a slight increase from the previous two census reports (1,083 in 2000 and 1,066 in 2010) and from the number of Native American residents reported in 1990 (940) and 1980 (803). An estimated additional 380 non-tribal persons lived on the reservation in 2021, including those married to tribal members and others who work for government agencies. Not all members of the Makah Tribe live on the Makah Reservation. Tribal enrollment, which includes the total number of tribal enrollees certified as being tribal members by the Tribe's leader or designee, was 3,357 members in 2022-2023 (the most recent year for which data are available) (B. Denney, Makah Tribe Planning Office Manager, pers. comm., March 21,2023). Table 3-32 shows selected demographics for American Indians living on the Makah Reservation.

Neah Bay, an isolated fishing and timber community of 1,079 persons, is the population center of the Makah Reservation, accounting for more than 70 percent of the reservation's population in 2021 (U.S. Census Bureau 2021f). Most of the Makah residing on the reservation live in Neah Bay, though some live in the reservation's hilly regions and along the road that runs south along the Pacific Ocean side of the reservation (Sullivan 2000).

3.7.3.2 Minority Employment

The subsections below provide information regarding minority employment potentially affected by the Makah's proposed gray whale hunts.

3.7.3.2.1 Clallam County

In 2021, Clallam County's minority civilian labor force totaled an estimated 5,404 persons (Table 3-33), representing 8.3 percent of the county's civilian labor force. Hispanics, who, for the purposes of the U.S. Census, may be categorized as members of other racial groups, had an estimated 2,495 persons in the labor force, accounting for 3.8 percent of the county's total labor force.

Unemployment for minorities in Clallam County is generally higher than for those in the overall countywide population. In 2021, the estimated unemployment rate for the county's minority population was 14.1 percent, compared to a countywide unemployment rate of 6.2 percent. Hispanics had lower unemployment figures than other minorities, at 6.7 percent.

Table 3-33. Labor force, employment, and unemployment for Clallam County minority and Native American populations, estimated for 2017-2021.

	Clallam County		Reservation Lands			
Category	**All Minority Persons[1]**	**Hispanics or Latinos[2]**	**Makah[3]**	**Quileute[3]**	**Lower Elwha[3]**	**Jamestown S'Klallam[3]**
In civilian labor force	5,404	2,495	691	104	289	145
Employed	4,872	2,276	587	87	249	145
Unemployed	761	241	104	17	40	0
Unemployment rate (%)	14.1	6.7	15.1	16.3	13.8	0

[1] This includes African Americans, Native Americans, Asians, Native Hawaiian and other Pacific Islanders, persons of some other race, and persons of two or more races.
[2] For purposes of the United States Census, Hispanics or Latinos may be of any race, so they are already included in other applicable race categories in the table.
[3] Data represent Native Americans on reservations reporting only one race and non-native residents living on the reservations .
Source: U.S. Census Bureau 2021c and 2021g

3.7.3.2.2 County Tribal Employment

Native Americans and non-native residents residing on the reservations of Clallam County's four tribes had a labor force of an estimated 1,229 persons in 2021, with an estimated 1,068 of these

persons employed (Table 3-33). About 56 percent of the labor force resided on the Makah Reservation, 23.5 percent on the Lower Elwha Reservation, 11.8 percent on the Jamestown S'Klallam Reservation, and 8.5 percent on the Quileute Reservation. Together, populations on the four reservations had an estimated unemployment rate of 13.1 percent in 2021, higher than the 6.2 percent rate countywide but lower than the 14.1 percent rate for all minority groups combined in Clallam County. The difference in unemployment rates between populations on the four reservations and the general population in the county may be higher than that reported by the U.S. Census because some residents on the reservations may have been available for work but dropped out of the labor force because of the lack of nearby employment opportunities.

Government employment is important to populations living on the county's four reservations (Table 3-34). Two industrial sectors linked to government (the public administration sector and the educational, health, and social services sector), generated about 44 percent of all jobs for reservations in 2021, including 57.1 percent of the jobs for the Makah Reservation, 33.3 percent of the jobs for the Quileute Reservation, 30.1 percent of the jobs for the Lower Elwha Reservation, and 22.1 percent of the jobs for the Jamestown S'Klallam Reservation. Industries related to agriculture, forestry, fishing, hunting, and mining are also important to the reservations, accounting for 12.5 percent of all job opportunities in 2021 (Table 3-34).

3.7.3.2.3 Makah Tribe

In 2021, the labor force of residents (primarily Makah but including non-native residents) on the Makah Reservation totaled an estimated 691 persons, representing 60 percent of the population 16 years old or older living on the reservation (U.S. Census Bureau 2021c). This labor force participation rate was about the same as the rate in 1990 and 1980 (U.S. Census Bureau in Northwest Area Foundation 2005).

As Table 3-33 shows, 587 residents on the Makah Reservation had jobs in 2021. The census data indicate that 15.1 percent of the labor force on the Makah Reservation was unemployed that year, an unemployment rate substantially higher than the 6.2 percent rate countywide. While relatively high, the unemployment rate suggested by the census data is much lower than the 70 percent and 54 percent unemployment rates reported by the Makah Tribe and the Bureau of Indian Affairs as recently as 2001 and 2003, respectively (Bureau of Indian Affairs 2001; 2003). Because of the seasonal nature of the reservation's tourist and fishing industries, unemployment is generally much higher during winter months than during the summer (Sullivan 2000).

Table 3-34. Employment by industry of Native American residents in Clallam County, estimated for 2017-2021.

	Makah Reservation[1]		Quileute Reservation[1]		Lower Elwha Reservation[1]		Jamestown S'Klallam Reservation[1]

[1] Data represent Native Americans on reservations reporting only one race and non-native residents on reservations

Source: United States Census Bureau 2021c

According to the 2017-2021 American Community Survey estimates, three industrial sectors of the local economy provided almost three-quarters of the jobs held by residents on the Makah Reservation in 2021. As discussed previously, two sectors associated with government activity (the public administration sector and the educational, health, and social services sector) together generated more than half of the employment opportunities for reservation residents (Table 3-34). Additionally, the industrial sector most closely related to the area's natural resources (the agriculture, forestry, fishing, hunting, and mining sector) provided 16.9 percent of the jobs held by residents on the Makah Reservation. Note that the survey, which estimated 99 jobs in this sector, may have underestimated the fishing-related employment in this sector. As noted in

Subsection 3.6.3.2.2, Employment, commercial vessels owned and operated by Makah tribal members generated approximately 515 jobs in 2011; because only Makah tribal members may participate in the Tribe's treaty fisheries, these jobs were only held by tribal members. This fisheries-related employment is seasonal in nature.

3.7.3.3 Personal Income and Poverty Levels

The subsections below provide information on personal income and poverty levels in Clallam County.

3.7.3.3.1 Clallam County

The income of minority populations in Clallam County is generally lower than that of the countywide population. According to the 2017-2021 American Community Survey estimates, the median household income (household income includes the income of all persons considered part of an individual household) for the overall population in Clallam County was $60,044 in 2021. The median household income was lower for all minority populations for which county-level data were available (Table 3-35). For Native Americans, the county's largest minority group, the median household income was approximately 35 percent lower than it was countywide. For Hispanics and Latinos, the next-largest group, the median household income was also approximately 35 percent lower than it was countywide (Table 3-35). County-level data were not available for two minority populations, African Americans and Native Hawaiian and other Pacific Islanders, because the sample size was too small (U.S. Census Bureau 2021h). Comparable data at the state level indicate that the median household income for African Americans in 2021 was 26 percent lower than the statewide median, while the corresponding value for Pacific Islanders was slightly higher (<1 percent higher) than the statewide median (U.S. Census Bureau 2021i).

The income differences between Clallam County's minority populations and its countywide population were even greater on a per capita income basis (per capita income is the total income of an area or population averaged across all persons within an area or population). In 2017-2021, per capita incomes of minority populations for which county data are available ranged from $20,214 (for Hispanics) to $28,391 (for Asians), compared to per capita income of $34,647 for the countywide population (Table 3-35). For Native Americans and Hispanics, per capita income levels were 35 percent and 42 percent lower, respectively, than the countywide per capita income. Similar to median household income, 2017-2021 county-level per capita income data for Native Hawaiians and other Pacific Islanders are unavailable because the sample size was too small (U.S. Census Bureau 2021j). Comparable data at the state level indicate that the per capita income

for Native Hawaiians and Pacific Islanders was 34 percent lower than the statewide value (U.S. Census Bureau 2021k).

Table 3-35. Income and poverty status of minority populations in Clallam County estimated for 2017-2021.

Racial Category	Median Household Income ($)	Per Capita Income ($)	Individuals Below Poverty Level
			Percent
Native American[1]	38,950	22,539	25.8
Asian[1]	71,094	28,391	21.7
Black or African American[1]	NA	26,441	19.1
Native Hawaiian and other Pacific Islanders[1,2]	NA	NA	5.9
Some other race[1]	48,667	25,898	8.5
Two or more races	52,411	25,156	15.5
Hispanic or Latino[3]	39,356	20,214	23.3

NA = not applicable.
[1] This only includes persons reporting a single race.
[2] Because of small sample sizes, county-level data were not available for Pacific Islanders.
3 For purposes of the U.S. Census, Hispanics or Latinos may be of any race, so they may already be included in other applicable race categories in this table.
Source: U.S. Census Bureau 2021h, 2021l, and 2021j

With the exception of the Native Hawaiian and other Pacific Islanders population and the population of some other races, the poverty rates (the poverty rate is the percentage of families or individuals living below the poverty thresholds established each year by the U.S. Office of Management and Budget) of all minority populations for which county-level data were available in Clallam County exceeded the countywide rate of 12.3 percent in 2021. The Native American population (25.8 percent) and the Hispanic or Latino population (23.3 percent) experienced the highest poverty rates (Table 3-35).

3.7.3.3.2 County Tribal Income

As discussed in Subsection 3.7.3.3.1, Personal Income and Poverty Levels for Clallam County, median household income and per capita income were lower for the Native American population in Clallam County than for the general countywide population in 2021. Additionally, the poverty rate for all Native Americans residing in Clallam County, at 25.8 percent in 2021, was higher than the countywide rate of 12.3 percent (Table 3-35).

For those living on Clallam County's four tribal reservations, median household and family income were much lower than countywide income levels in 2021. Median household income for those living on reservations was 21 to 51 percent lower than the county's median household income of $60,044 (Table 3-36). Similarly, median family income for reservation families was 21 percent to 52 percent lower than the countywide median family income of $72,025.

Table 3-36. Income and poverty status of residents on reservations in Clallam County, estimated for 2017-2021.

Category	Makah Reservation[1]	Quileute Reservation[1]	Lower Elwha Reservation and Trust Lands[1]	Jamestown S'Klallam Reservation and Trust Lands[1]
Median household income ($)	47,167	29,500	29,444	NA[2]
Median family income ($)	57,000	34,167	34,375	NA[2]
Per capita income ($)	21,371	16,016	18,693	NA[2]
Percent of families below poverty level (%)	17.2	43.9	9.6	2.7
Percent of individuals below poverty level (%)	20.6	40.6	31.1	3.3

[1] Data represents Native Americans reporting only one race and non-native residents living on the reservations.
[2] For the Jamestown S'Klallam Reservation and trust lands, there were either no sample observations or too few sample observations available to compute an estimate.
Source: U.S. Census Bureau 2021c, 2021m-r

A larger disparity between tribal and countywide income exists for per capita income. From 2017-2021, estimated per capita income for tribal reservation residents ranged from $16,016 for the Quileute Reservation to $21,317 for the Makah Reservation (Table 3-36). These income levels are approximately 57 to 68 percent lower than the $49,718 per capita income for the countywide population in 2012 (Vleming 2022).

Given the disparity in incomes, poverty rates for families and individuals living on the reservations are substantially higher than for the general countywide population, except for those living on the Jamestown S'Klallam Reservation and Trust Lands. Excluding the Jamestown S'Klallam Reservation and Trust Lands, the percentage of reservation families with incomes below the federal poverty threshold ranged from 9.6 percent to 43.9 percent in 2021 (Table 3-36), compared to 8.0 percent of families countywide in 2021 (U.S. Census Bureau 2021s). For individuals living on the reservations (excluding the Jamestown S'Klallam Reservation and Trust Lands), poverty rates ranged from 20.6 to 40.6 percent in 2021, much higher than the countywide poverty rate of 12.3 percent.

3.7.3.3.3 Makah Tribe

Native Americans and non-native residents living on the Makah Reservation have substantially lower incomes and experience higher poverty rates than residents throughout Clallam County. According to the United States Census Bureau, the median household income of those living on the Makah Reservation was $47,167 in 2021 (Table 3-36), 21.5 percent lower than the countywide median household income. Relative to median household income on reservations throughout the United States, the median income of tribal households on the Makah Reservation has been falling over the past three decades. In 1979, the median household income of American Indians on the Makah Reservation was 48 percent higher than the median household income of all United States reservations. By 2021, this was no longer the case: the median household income of those living on the Makah Reservation was approximately 11 percent lower than the median household income of Native Americans and Alaska Natives nationwide ($53,149) (U.S. Census Bureau 2021t).

Similar to household income, the per capita income of Makah Reservation tribal members is lower than per capita income countywide, registering 43 percent of the countywide level in 2021. The disparity in income levels explains the relatively high poverty rates for Native Americans residing on the Makah Reservation. In 2021, 17.2 percent of the families residing on the Makah Reservation fell below the federal poverty level (Table 3-36) compared to 8.0 percent of all families in Clallam County (U.S. Census Bureau 2021s). Poverty figures for individuals were similar to those for families, with 20.6 percent of the Makah Reservation's residents living below the poverty level compared to 12.3 percent of all individuals in Clallam County. During the 2022 to 2023 school year, 75 percent of the students in the Cape Flattery School District qualified for free or reduced lunch programs, based on family incomes below the federal poverty threshold (Office of Superintendent of Public Instruction 2022). The comparable value statewide was 52 percent. Approximately 56 percent of the students in the school district (which includes schools in Neah Bay and Clallam Bay) are identified as American Indian or Alaskan Native, compared to 1.3 percent statewide. As another indicator of the level of need in the community, approximately 152 households on the reservation rely on food banks and federal food programs to feed their families (Renker 2018).

3.7.3.4 Outreach to Minority and Low-Income Populations

Outreach to minority and low-income populations was part of the overall scoping process NMFS conducted for this FEIS. Subsection 1.5.1, Scoping Process, of this EIS contains a description of the scoping process, as does the scoping report associated with this EIS.

3.8 Social Environment

3.8.1 Introduction

This section discusses the social environment, including the apparent emotions and attitudes of people and communities potentially affected by the Makah whale hunt. The range of emotions and attitudes, as well as the resulting tensions, are described below in the context of the various groups that have expressed an interest in the hunt. The information in this section primarily comes from the period prior to release of the 2008 DEIS, as no Makah hunt has been authorized during the intervening period and there has been no unauthorized hunting.

3.8.2 Regulatory Overview

No specific regulations directly address social tensions in the action area. However, the Coast Guard has established an RNA that allows it to enforce vessel activities (including protesters' vessels) near any Makah whale hunt and reduce the danger of loss of life and property (Subsection 3.1.1.3, Coast Guard Regulated Navigation Area).

3.8.3 Existing Conditions

3.8.3.1 Makah Tribal Members

The Makah Tribe values whales for their ceremonial and subsistence uses, including the spiritual role they play in Makah culture. According to the Application for a Waiver of the Marine Mammal Protection Act Take Moratorium to Exercise Gray Whale Hunting Rights Secured in the Treaty of Neah Bay, the Makah Tribe has attempted to revive its cultural traditions for the past three decades (Makah Tribe 2005). The Tribe believes it must revive these traditions to combat the social disruption resulting from the rapid changes of the last century and a half. The document states that rates of teenage pregnancy, high-school dropout, substance abuse, and juvenile crime indicate that the Makah community is still in flux and that the enormous social disruption caused by epidemics, boarding schools, and federal acculturation policy still exists. To reverse these trends, the Makah have reinstituted numerous song, dance, and artistic traditions. The Tribe currently operates a program to restore the Makah language to spoken proficiency on the reservation. Given the centrality of whaling to the Tribe's culture, the Makah Tribe believes that a revival of subsistence whaling is necessary to pursue its spiritual renaissance (Makah Tribe 2005).

In preparation for the 1999 whale hunt, tribal participants engaged in both spiritual and physical training for the hunt. Overall, Makah tribal members experienced an increase in tribal pride (Bowechop 2004) through this preparation. This revival of Makah whaling rituals and traditional knowledge occurred after a voluntary 70-year hiatus (Section 3.10, Ceremonial and Subsistence

Resources) in whale hunting. Hunters reported that the activities accompanying the hunt strengthened tribal member identity as descendants of Makah whalers (Tweedie 2002). One of the elders who grew up speaking Makah reported that Makah language class attendance swelled after the hunt (Oldham 2003). Many community members were present when the first whale was landed at Neah Bay in 1999, and 80 percent of the community attended the tribal celebration of the first whale hunt (Makah Tribe 2005). Most Makah felt that the restoration of whaling had improved social and cultural conditions on the reservation. Subsistence whaling, both in the historic and contemporary contexts of the Makah culture, is further discussed in Subsection 3.10.3.4, Makah Historic Whaling, and Subsection 3.10.3.5, Contemporary Makah Society, respectively.

Although most Makah tribal members support the hunt, some do not. According to a 2001/2002 household whaling survey the Makah Tribe conducted, 93 percent responded that the Makah Tribe should continue to hunt whales, 6 percent responded that the Tribe should not hunt whales, and 1 percent was undecided (Renker 2002; 2007). This and subsequent surveys are described further in Section 3.10, Ceremonial and Subsistence Resources. One Makah tribal member has publicly opposed the hunt and spoke at the 1996 annual IWC meeting. She reported encountering harassment and hostility from pro-whaling tribal members (Mapes 1998b). According to a newspaper account, other members who did not approve of the hunt were less vocal about their dissent (Mapes 1998c). The article indicated that those who spoke out were criticized for disloyalty to their leaders and for exposing tribal dissention to the outside world. According to Keith Hunter, a Neah Bay resident who is not a Makah tribal member, there has been no opposition to whaling of the sort portrayed by many of the anti-whaling advocates (CERTAIN 2000). Hunter claimed that disagreements, concerns, or differences almost entirely healed, and those remaining disappeared on the day the Makah took the whale.

Many people beyond the reservation do not support whaling, and protests were common during the hunting periods (Subsection 1.4.2, Summary of Recent Makah Whaling – 1998 through 2007, and Subsection 3.15.3.4, Behavior of People Associated with the Hunt). Makah tribal members have expressed frustration with protesters and others who oppose the whale hunt. They believe that protesters, like missionaries and government Indian agents preceding them, are pushing their cultural values on the Makah people and telling them how and how not to be Makah (Johnson 1999).

The Makah Tribal Council provided financial support to both the whaling captain and whaling crew as they were training for the hunts in 1998 and hunting in 1999 and 2000. In 2002, the

Council decided not to provide financial support, leaving it up to whaling families to support any hunts, consistent with tribal tradition. In 2002, at least three families were interested in a hunt, and two were actively training (Mapes 2002). The Makah Tribal Council has not indicated whether it would financially support future hunts if they were authorized. In the years since the 2008 DEIS was released and those involved in the unauthorized hunt were prosecuted, the Makah Tribe has continued to demonstrate its desire for a whale hunt; for example, by renewing its requests at the IWC and continuing to ask NMFS to complete its consideration of the waiver request.

3.8.3.2 Other Tribes

Many other tribes supported, and continue to support, the Makah's right to hunt whales, in part because they want the federal government to uphold the rights enshrined in the Treaty of Neah Bay. In 1999, the *Peninsula Daily News* reported that thousands of Native Americans from Canada to New Mexico anticipated journeying to Neah Bay for a feast to celebrate the successful hunt (*Peninsula Daily News*, the *Associated Press*, and *Seattle Times* 1999). The hunt was supported by the Northwest Indian Fisheries Commission, an organization of 20 member tribes in western Washington, and the president of the Northwest Indian Fisheries Commission gave a speech at the celebratory feast after the whale was killed (Bowechop 2004). In 2003, the Affiliated Tribes of Northwest Indians passed Resolution 03-13 in support of the Makah whaling treaty rights. In 2004, the National Congress of American Indians passed Resolution MOH-04-025, stating the following:

> . . . go on the record in full support of the right of the Makah to freely exercise their treaty right to hunt whales while supporting the rights of Fishing Tribes to marine mammal management without threats, intimidation, harassment, or interference.

The National Congress of American Indians also expressed support for the Makah after the *Anderson v. Evans* (2004) decision. It called upon the U.S. Government and all of its agencies to "support the efforts of the Makah Tribe and affected tribes to restore its full treaty whaling rights." In a 2005 scoping letter on the DEIS, Honor Our Neighbor's Origins and Rights registered its support of the treaty-protected right of the Makah to pursue whaling. A Puyallup Tribe member supported this idea in an interview with the *Seattle Times* by noting the importance of Makah whaling in the context of tribal rights. He mentioned the importance of solidarity, saying "One of the ways we were conquered was by dividing us" (Hamilton 1999a). The Northwest Indian Fisheries Commission, Jamestown S'Klallam Tribe, Squaxin Tribe, Lower Elwha Klallan Tribe, Suquamish Tribe, Tulalip Tribes, Puyallup Tribe, and Swinomish Tribe also submitted public comments in support of the Tribe's waiver request during a public comment

period on the ALJ's recommended decision in 2021. Some individual Native American commenters for this EIS did express opposition to the hunt; a summary of the views of these and other individuals is encapsulated below in Subsection 3.8.3.3, Other Individuals and Organizations.

Immediately after the successful 1999 whale hunt, anti-whaling activists targeted the Muckleshoot, Puyallup, and Tulalip Tribes for their support of the Makah's whale hunt (Burkitt 1999a). The tribes received verbal threats and insults, including a bomb threat to a tribal school (Burkitt 1999a).

3.8.3.3 Other Individuals and Organizations

This section covers the range of attitudes about Makah whale hunting held by Clallam County residents, Washington State residents, U.S. residents, foreign nationals, and people affiliated with non-governmental organizations. Both local and out-of-state residents have expressed support for and opposition to the Makah whale hunt. This section also covers the attitudes of potential tourists who may or may not choose to visit the area because of their perceptions of the whale hunt.

Although the debate can often be characterized as polar extremes of whaling proponents and whaling opponents, the complicated views cannot be reduced to two simple perspectives (Sepez 2002). Some people believe, for instance, that all whaling, including commercial whaling, is acceptable as long as the whale resource remains at a sustainable level based on scientific, principled management. Some people believe that commercial whaling is unacceptable but that subsistence whaling for aboriginal cultures is acceptable. Some people believe that whaling for any purpose is unacceptable and should not be allowed. The debate about how to manage whales involves culturally-based values (Freeman 1994).

In the 1970s, the popular Save the Whales conservation movement began, with the objective of preventing the extinction of whale species (Sepez 2002). Information about whales and whaling was advertised by media releases, films, television programs, aquarium shows, videos, books, magazines, paintings, and whale-watching businesses, among other things (Barstow 1996; Sepez 2002). Over time, stemming from the unsustainable commercial whaling practices in the past, an ideological debate has emerged concerning the appropriateness of any whale hunting (Freeman 1994; Stoett 1997). Whales have become symbolic of the need to protect the natural environment, at least in western societies (Barstow 1996; Stoett 1997).Specific to the Makah's past and proposed whale hunting activities, we received public comments on the 1997 EA, the 2001 EA, the 2008 DEIS, the 2015 DEIS, the 2019 ALJ hearing transcript, the 2021 ALJ recommended

decision and proposed rule, and the 2022 SDEIS. The commenters are not necessarily divided along cultural lines (people from indigenous cultures versus people from western societies). Some Native American commenters and individual Makah tribal members interviewed in the past disagree with the hunt. Some commenters who did not identify themselves as Native Americans support the hunt. Commenters who have supported or would support the Makah hunt give many reasons for their support, including, but not limited to, their perception of the established treaty whaling right of the Makah Tribe and federal obligations to the Makah Tribe (Subsection 1.2.2, Treaty of Neah Bay and the Federal Trust Responsibility); the relative health of the gray whale population (Subsection 3.4.3.3.4, ENP Status, Carrying Capacity, and Related Estimates); and the historical and contemporary cultural meaning ascribed to whaling by the Makah (Section 3.10, Ceremonial and Subsistence Resources).

Commenters who did not or would not support the Makah's hunt of gray whales also gave a multitude of reasons, some of them related to social and economic values attributed to the gray whales. Several people, for instance, commented on the beauty of the whales and the emotions they inspire. Many people oppose the killing of whales because they believe whales are intelligent (comparable in this regard to humans) and have sophisticated forms of community and communication. One review states, "stranger than fiction is fact that there already exists a species of animal life on earth that scientists speculate has higher than human intelligence. The whale has a brain that in some instances is six times bigger than the human brain and its neocortex is more convoluted" (D'Amato and Chopra 1991). In a letter to the *Seattle Post-Intelligencer* editor, one person wrote ". . . I believe whales and other marine mammals are intelligent, and for lack of opposable thumbs, might be creatures equal to humans on the evolutionary ladder" (*Seattle Post-Intelligencer* 1999). In addition, human-like characteristics of whales, such as humpback whales' complicated communication system and the strong family grouping of orcas, particularly endear whales to people (Sepez 2002). Some people also believe that whales are sentient beings that should be allowed to exist free from human harm.

People both inside and outside of the United States have said that they value the existence of gray whales in the action area as fellow mammals, and they want to know that whales exist unmolested. Many people (mostly local residents) who watch whales in the analysis area on a regular basis attach existence values to individual PCFG whales who regularly visit the area. Many people were also concerned about the pain individual whales experience if struck or killed in a hunt. Some people believe that cruelty is unavoidable in methods for a whale hunt (Freeman 1994).

After the 1999 hunt, many people expressed remorse and anger about the whale hunt in protests in Seattle and Port Angeles in letters and calls to local and regional newspapers such as the *Peninsula Daily News*, the *Seattle Times*, and the *Seattle Post-Intelligencer*. The *Seattle Times* reported that they received almost 400 phone calls and emails running about 10-to-1 against the hunt within hours of the Makah Tribe's successful kill of a gray whale (*Seattle Times* staff 1999). Many people's comments were reactions to the images of the killing of the whale on the morning television news. Some thought the coverage of the killing was inappropriate for television news (Levesque 1999). Some protesters and comment writers expressed violent feelings and displayed racism towards the Makah.

Some comments on the 2008 DEIS suggested that people would boycott products and not participate in tourism on the peninsula and throughout the state as a result of whaling. They were concerned that whaling would cause economic impacts on hotels, restaurants, stores, and tourist-related businesses. Some people opposed using modern technology for the hunt, suggesting that a traditional hunt should be conducted using traditional technology (Subsection 2.4.5.1, Hunt Using Only Traditional Methods). While most letters and calls received by newspapers after the successful 1999 whale hunt opposed the whale hunt, many commenters expressed support for the Tribe and the hunt. One letter said, "It is the right of the Makah to keep their culture alive and if whale hunting is part of it, so be it!" (*Peninsula Daily News* 1999). Some comments on the 2008 DEIS also expressed support for the hunt, remarking on tourist interest in whaling, cultural diversity, and the importance of upholding treaty rights. One comment received during scoping for the 2008 DEIS indicated that the Pacific Northwest embraces all cultures and practices and that people come to the area because of this diversity.

Organizations that oppose whaling in general include animal-rights and marine conservation organizations, the whale-watching industry, and anti-treaty constituents. Some of these groups are opposed to the Makah whale hunt, while others think that aboriginal whaling is an acceptable form of whaling if conducted in a sustainable manner. More than 350 groups from 27 countries have expressed opposition to the Tribe's whale hunt (Oldham 2003).

In 2002, after the IWC renewed the gray whale catch limits in response to the joint request from Russia and the United States, some anti-whaling groups announced they would not obstruct the Makah hunt directly (Watson 2002), and one group expressed concern that opposition to the hunt might be misinterpreted as opposition to treaty rights (Mapes 2002).

Most whale-watching tour operators are opposed to whale hunting primarily for economic reasons. Some scoping comments expressed concerns that a gray whale hunt would affect local

and regional whale-watching industry revenues by causing whales to avoid boats. The West Coast Anti-Whaling Society, made up of professional whale-watching tour guides, is one group that has opposed Makah whaling (Hamilton 1999b). More information on the whale-watching industry is available in Subsection 3.6.3.2.4, Contribution of Tourism to the Local Economy.

Of the 49 self-identified Washington State residents that submitted public comments on the ALJ's recommended decision in 2021 (not including Tribes), 37 indicated strong opposition to the proposed waiver. While Clallam County residents have expressed the range of attitudes about Makah whale hunting described above, a more intense debate about the issue seems to be occurring in and near Clallam County because of proximity to Neah Bay. This intense debate, which includes strong disapproval of and support for the hunt, is evident in the many interactions with Clallam County residents, including scoping letters for the 2008 DEIS; verbal scoping comments recorded at the Port Angeles DEIS scoping meeting; letters and calls from Clallam County residents received after the successful 1999 whale hunt; written and verbal comments on the 2008 DEIS; and whaling protests in Port Angeles. Of those Clallam County residents who expressed a view during scoping and on the 2008 DEIS, more expressed disapproval of the hunt than those expressing support for the hunt.

A local group called Peninsula Citizens for the Protection of Whales actively opposes the hunt and participated as a party to the 2019 ALJ hearing. The group's 2006 scoping letter and comments on the 2008 DEIS expressed fear that continued whaling will divide the community and the many tribes in the area will be drawn into the controversy. Members of the group protested near the Makah reservation border in the spring of 1999 (Porterfield and Denn 1999). Another local group, Washington Citizens Coastal Alliance, based in nearby Friday Harbor, sent out a travel advisory to several hundred travel organizations, media groups, and individuals, expressing opposition to whaling (Hamilton 1999b). The advisory warned potential tourists to Neah Bay of recent conflicts and violence stemming from the whaling issue. The *Seattle Times* reported that other activists have said that the controversy was ripping apart rural Clallam County and Washington as a whole (Welch 2001).

Several incidents involving violent or near-violent confrontations between whaling opponents and members of the Makah Tribe have occurred in Clallam County since the Tribe first announced its intention to hunt whales in 1995. It is difficult to determine which protesters are local residents and which are representatives of anti-whaling organizations based outside the area. An anti-whaling activist meeting in Port Angeles in 1998 was the scene of a near-riot when Makah tribal members arrived to support whaling (Peterson 2000). One incident in 1999 involved two animal-

rights activists tossing ignited smoke canisters at a tribal motorized support boat and throwing an ignited flare into the water near the boat (Porterfield and Denn 1999). Another incident involved a protest boat being pelted with rocks and bottle rockets after a group of protest boats converged inside the Neah Bay Marina (Gottlieb 1999). One man burned the American flag and tires in a Port Angeles park in protest of the whale hunt (Gottlieb 1999). During and after the successful 1999 whale hunt, Makah tribal members and the Coast Guard received emails and phone calls with death threats and anti-whaling messages (Hamilton 1999c). Some tribal members have been refused service at businesses in Port Angeles (Hamilton 1999c). Refer to Subsection 1.4.2, Summary of Recent Makah Whaling – 1998 through 2007, and Subsection 3.15.3.4, Behavior of People Associated with the Hunt, for a more complete description of protest activities.

Other evidence of heightened local tensions can be found in a 2001 letter from the Port Angeles Chief of Police and Clallam County Sheriff to NMFS, asking NMFS not to hold public hearings on the whaling issue in Port Angeles for the 2001 EA. The request was made because of concerns that violent demonstrations would overwhelm the resources of local law enforcement (Port Angeles Police Department 2001).

3.9 Cultural Resources

3.9.1 Introduction

The following section discusses the cultural resources in the action area that may be affected by the action alternatives.

3.9.2 Regulatory Overview

Federal and state laws protect and preserve cultural resources. The United States' first preservation law, the Antiquities Act of 1906, was updated and expanded in 1966 when Congress enacted the National Historic Preservation Act, declaring that "the historical and cultural foundations of the Nation should be preserved as a living part of our community life and development in order to give a sense of orientation to the American people." Thus, the National Historic Preservation Act established a national historic preservation program that has operated as a decentralized partnership between the federal government and the states. The National Historic Preservation Act, amended in 1980 and again in 1992 (16 USC 470 *et seq.*), identified a leadership role for the federal government in historic preservation. Through a partnership with the states, in addition to relationships with Indian tribes, local governments, and private organizations, the National Historic Preservation Act fosters conditions "under which our modern society and our prehistoric and historic resources can exist in productive harmony." These relationships provide broad participation in national historic preservation programs, while

maintaining standards consistent with the National Historic Preservation Act and the Secretary of the Interior's *Standards and Guidelines for Archaeology and Historic Preservation* (48 FR 44716, September 29, 1983).

Federal agency requirements to consult with Indian tribes are clarified in the Advisory Council on Historic Preservation's regulations, Protection of Historic Properties (36 CFR Part 800), implementing section 106 of the National Historic Preservation Act. These regulations emphasize participation in this process by state historic preservation officers and the public, including Native American groups. The federal agency must consult with the tribal historic preservation officer for projects occurring on Indian reservations or potentially affecting a tribe's off-reservation traditional cultural properties.

Archaeological resources on federal lands received federal protection under the 1979 Archaeological Resources Protection Act and the 1990 Native American Graves Protection and Repatriation Act. Federal law applies to all federal and Native American lands, and Washington State law applies to all other lands within the action area. Washington State Executive Order 05-05 provides for the Department of Archaeology and Historic Preservation to review certain projects not undergoing section 106 review to determine potential impacts to cultural resources. With respect to cultural resources within the Makah Tribe's traditional territory, the Tribe takes an active role in the documentation and preservation of these resources, including the assessment of potential impacts to its cultural resources.

3.9.3 Existing Conditions

3.9.3.1 National Historical Register Sites

There are two historic sites listed on the National Register of Historic Places near the action area where a whale could be landed (i.e., the Makah U&A waters and shoreline). The first is Tatoosh Island, which was a summer home to the Makah Tribe. The Makah landed whales on Tatoosh Island. A lighthouse was erected there in 1857. The second listed site is Wedding Rock Petroglyphs, located on the beach between the Ozette and Sand Point Trails in the coastal strip of the Olympic National Park (i.e., Ozette Triangle). The Wedding Rock Petroglyphs are located in the rocks near the high tide line, and they attract many visitors each year.

3.9.3.2 Archaeological Sites

Around 1750, a substantial section of the Ozette village on the outer coast of the Olympic Peninsula was encased in a spring mudslide. This anaerobic environment preserved wood, bone, textile, and cordage to create unprecedented archaeological preservation. More than a decade of archaeological excavations at this site, beginning around 1970, yielded 55,000 artifacts,

12,000 structural remains, and more than 1 million faunal remains. These archaeological investigations revealed about 2000 years of human occupation along the Olympic Peninsula in the Late Period of the Northwest Coast (Wessen 1981).

3.9.3.3 Other Culturally Important Sites

Of particular assistance in determining the presence and location of traditional cultural properties was the "Makah Traditional Cultural Property Study," prepared for the Office of Archaeology and Historic Preservation, State of Washington, Olympia, in cooperation with the Makah Cultural and Research Center, Neah Bay (Renker and Pascua 1989). That study recognized the entire Makah traditional territory as a traditional cultural property. For the purposes of this FEIS, however, the definition of a traditional cultural property was narrowed to include only those sites known to be directly associated with whaling for which the location has been reported. Makah elders identified First Beach, situated immediately adjacent to Neah Bay, as a site associated with butchering whales. A review of the ethnographic literature did not locate other sites that would meet the criterion of a traditional cultural property for this FEIS.

First Beach, situated next to Neah Bay, was where the chief of the Neah Bay village towed whales for flensing. It was known in the Makah language as *čiʔ·ʔawa·ʔiyak*, "place for butchering whales." Renker and Pascua (1989, no. 190) listed this site as a traditional cultural property retaining significance to the Makah Tribe. Other chiefs towed harvested whales to beaches closer to their villages.

There are several, unlisted shell midden sites in the Olympic National Park, and these are actively exposed along eroding beach terraces. There are also unlisted whaling sacred sites where Makah Tribe whaling families and members would prepare for whaling. The locations of such sites are regarded as private knowledge that is not generally divulged to non-family members. There are no specific known locations that the Tribe uses continually and that could be considered historical sites.

In May 2008, the Fort Núñez Gaona – Diah Veterans Park was dedicated in Neah Bay. The monument, a collaboration of the Makah Tribal Council, the Spanish government, the Washington Office of Lt. Governor, Neah Bay area veterans, and members of the local community, is located at the site where the Spanish anchored in Neah Bay and laid claim to Cape Flattery in 1790. The monument also serves as a memorial to the Neah Bay veterans who served in the U.S. military.

3.10 Ceremonial and Subsistence Resources

3.10.1 Introduction

The following subsection presents the cultural aspects of the Makah Tribe's proposal to hunt gray whales for subsistence and ceremonial purposes (refer to Section 3.16, Human Health, for further information about the nutritional aspect of subsistence and ceremonial hunting). This section also includes a discussion of the symbolic value of the whale to the Makah people's cultural identity.

3.10.2 Regulatory Overview

The American Indian Religious Freedom Act of 1978 (42 USC 1996) contains the following language:

> . . . it shall be the policy of the United States to protect and preserve for American Indians . . . their inherent right of freedom to believe, express and exercise [their] traditional religions,. . . including but not limited to access to sites, use and possession of sacred objects and the freedom to worship through ceremonials and traditional rites.

Additionally, the Religious Freedom Restoration Act of 1993 (42 USC 2000b) provides protections for religious practice. The statute places the initial burden on a person to establish that religious practices have been substantially burdened. The Makah have asserted that the spiritual and ceremonial practices associated with whaling are protected by these two statutes (Makah Tribe 2006b).

In the Treaty of Neah Bay, the Makah Indian Tribe reserved its right to engage in subsistence activities, including hunting, fishing, whaling, and sealing in its usual and accustomed grounds (Subsection 1.2.2, Treaty of Neah Bay and the Federal Trust Responsibility). In the Ninth Circuit decision in *Anderson v. Evans*, the Court of Appeals expressly stated that ". . . [w]e need not and do not decide whether the Tribe's whaling rights have been abrogated by the MMPA." The court also noted that ". . . [u]nlike other persons applying for a permit or waiver under the MMPA, the Tribe may urge a treaty right to be considered" during review of the Makah Tribe's request (*Anderson v. Evans* 2004).

3.10.3 Existing Conditions

The Makah call themselves *qʷidičča7a·tx,ˇ* which is generally thought to mean "residents of the place of rocks and seagulls." They are, however, best known by the current anglicized name which is an incorrect pronunciation of a Salish term *máqaʔa* that means "generous with food" (Renker 2013). The Makah Tribe continues to reside on lands within their traditional territory situated on the northwest tip of the Olympic Peninsula, bordered by the Strait of Juan de Fuca and

the Pacific Ocean. Tribe members maintain a strong orientation to the sea and the resources it provides.

Both linguistically and culturally, the Makah people were closest to the Ditidaht and Nuu-chah-nulth peoples of western Vancouver Island, with whom they shared the occupation of whaling. While ties to these Canadian neighbors continue, the people of the contemporary Makah Tribe participate with other western Washington tribes as members of the Northwest Indian Fisheries Commission, whose mission is the conservation of fisheries (Northwest Indian Fisheries Commission 2023).

3.10.3.1 Makah Archaeological Resources Connected with Whaling

Much of the archaeological and historical evidence of the Makah whaling tradition was obtained through a large excavation of a Makah whaling village (Ozette) that was occupied by the Makah Tribe from 400 B.C. to 1920 (Subsection 3.9.3.2, Archaeological Sites). These archaeological investigations revealed about 2000 years of human occupation along the Olympic Peninsula in the Late Period of the Northwest Coast (Wessen 1981).

Aboriginal people began moving from interior riverine sites to the bays along the Pacific Ocean around 400 B.C., where they then adapted to a maritime orientation. This adaptation brought about an increase in sea mammal hunting, including whaling, which, along with deep sea fishing, necessitated the development of the large, seagoing canoes described ethnographically by Waterman (1920). An archaeological walking survey of Makah territory, complemented with test excavations at six additional sites representing divergent environmental zones, indicated that all of the investigated sites shared an orientation towards sea mammal hunting that was seen most clearly at Ozette (Friedman 1976).

Based on the recovery of whaling equipment and whale bones with embedded fragments of harpoon blades at the Ozette excavation, archaeologists determined that, for at least 1,500 years, the Makah Tribe paddled out to sea to hunt whales. Earlier, as evidenced by butchered whale bone in archaeological deposits, the Makah Tribe harvested drift and stranded whales (Huelsbeck 1994). Moreover, the number of whale bones recovered from different areas of the site which represented different time periods did not vary, suggesting that whaling remained stable. Artifacts recovered archaeologically indicate that whaling techniques described ethnographically by Drucker (1951) were used prehistorically (Huelsbeck 1994). Canoe fragments, harpoon shafts, harpoon heads, sinew ropes, and wooden plugs from seal skin floats have all been found (Huelsbeck 1994).

The skeletal remains of the gray whale and humpback whale were both equally represented and were the dominant whale species recorded in the deposits when the whale species could be identified, suggesting that they were actively pursued by Makah hunters. Most of the excavated bones identified as whale could not, however, be identified to species because of limitations of the comparative material available (Huelsbeck 1994).[71] From the skeletal material that could be identified, archaeologists concluded that, at Ozette, whales represented much more food than all the other kinds of animals combined (Huelsbeck 1994). Researchers estimated that as much as 85 percent of the pre-contact (i.e., before the first arrival of Europeans in the late 18th century) diet of the Makah Tribe could have been composed of whale meat, oil, and blubber (Huelsbeck 1988). Archaeological evidence in the form of roughly cut and gouged bones suggests that the Makah, in addition to rendering blubber for oil, extracted oil from bones, a practice not reported ethnographically (that is, through interviews with Makah elders) or through observation of their practices. In addition, partially burned bone suggested roasting as a method of cooking the meat (Huelsbeck 1994). Fragments of whale skin were also found inside the remains of houses at Ozette, a finding consistent with Koppert's (1930) remark that whale skin was eaten. While Koppert (1930) thought that the entire whale was used, other reports differed on the extent of carcass used and/or consumed by the Makah (Waterman 1920).

3.10.3.2 Makah Cultural Environment

At the time of the Treaty of Neah Bay, the Makah Tribe permanently occupied five villages situated on the northwestern tip of the Olympic Peninsula: *di·ya·* or Neah Bay; *bi?id?a* or Biheda; *wa?ačˇ* or Wayatch; *čˇu·yas* or Tsoo-Yess; and *?use·?iɬ* or Ozette. In addition to these five semiautonomous winter villages, Makah families occupied seasonal sites, such as fishing camps on the outer coast (Friedman 1976; Renker and Gunther 1990).

Anthropologists classify the Makah Tribe within the Nootkan (Nuu-chah-nulth) subdivision of the Northwest Coast Cultural Area, a cluster of societies that share certain traits and trait complexes. Drucker (1951) defines these traits as:

- A marine and riverine orientation that permeated not only subsistence practices but ideology and outlook.
- An emphasis on fishing and marine mammal hunting, as well as the gathering of shellfish, other marine invertebrates, and plants.

[71] More recently, Alter et al. (2012) identified DNA of gray, humpback, blue, and sperm whales from bones excavated at sites on the Makah and Quileute Reservations.

- A highly developed woodworking technology.
- A tripartite system of social stratification that included nobles, commoners, and slaves.
- An emphasis on property, both tangible and noncorporeal.
- The integration of rank and kinship as the basis for social interaction.

The Makah Tribe's location and wealth in natural resources placed tribal members at the hub of a far-reaching trading network that extended north to Vancouver Island, south to the Lower Columbia River, and east to the tribes of the Strait of Juan de Fuca. Whale oil and other coastal products passed along this network (Swan 1870; Renker and Gunther 1990).

3.10.3.3 Historic Makah Community

The Makah winter village was the primary residential community. The people lived in large, shed-roofed, cedar plank dwellings during the rainy winter months when resource harvesting activities were low and ceremonial life was more active. People identified themselves primarily with their winter village, but individuals maintained kinship ties with several villages, not all of them Makahs. Kin units among the Makah were organized on the basis of non-unilinear descent, meaning that members all acknowledge descent from a common ancestor traced through either males or females. Leadership tended to be controlled by a patrilineal core of elite residents, generally consisting of a father and his sons with their families, resulting in households being quasi-lineages that controlled production, consumption, and resources. Hence, these elite groups of kinsmen were the headmen of the households who owned the resources and organized the work of others for resource harvest and distribution.

The elite members of Makah society were the titleholders, the chiefs or nobles who held rights to inherited leadership positions. Despite their considerable prestige and ritual authority, however, they held limited political power. Chiefs had influence but could seldom compel other individuals to act against their will. Commoners and slaves formed the lower two strata of society. Commoners enjoyed the privileges of membership in their descent group and had access to resources and ceremonial prerogatives, although commoners did not have rights to ranked titles. Slaves, obtained through capture or purchase from other tribes, were human property devoid of rights (Drucker 1951; Colson 1953; Renker and Gunther 1990). Such distinctions in rank and status declined following guidelines set forth in the Makah Tribe's 1855 Treaty and the establishment of the Neah Bay Indian Agency in 1863. Under the influence of Indian agents who promoted assimilation, the Makah Tribe's pre-contact, visible sociopolitical organization was weakened. In 1879, the community of Neah Bay held its first election for headmen, the result of

which was recorded by James Swan, who noted that similar proceedings were soon to be held at the other Makah villages (Goodman and Swan 2003).

3.10.3.4 Makah Historic Whaling

At least seven species of whale are distinguished in the dialects of the Makah Tribe and their Nuu-chah-nulth neighbors (Swan 1870; Sapir 1910 to 1914; Waterman 1920; Densmore 1939; Stonham 2005), and archaeological remains have been found for at least eight cetacean species (Etnier and Sepez 2008), including blue, gray, humpback, and sperm whales (Alter et al. 2012). From review of the ethnographic record, especially the work of Drucker (1951), whales, from the perspective of the Makah Tribe and neighboring indigenous groups on the Northwest Coast, differed little from humans: both have human form, live in houses (although the whales' home is at the bottom of the ocean), and travel about in canoes. The Tribe and neighboring indigenous people believed that the familiar bulbous gray form observed as whale (gray or humpback) was merely a whale spirit riding in its canoe while fishing (Sapir 1910 to 1914). By means of the whaler's ritual supplications, the whale's spirit was enticed to leave its canoe, which allowed the whale's body to be caught (Jonaitis 1999).

Ethnographic reports indicate that Makah tribal hunters pursued mostly gray and humpback whales (Waterman 1920; Drucker 1951), while skeletal remains in archaeological sites suggest that right whales and fin whales may have been taken occasionally, and sperm and killer whale remains probably represent salvaged drift whales (Huelsbeck 1988). The unifying characteristic of those whale species the Makah pursued was a slow swimming speed, enabling their capture by men in canoes. The hunting season for gray whales began in March, when they appeared in numbers off Tatoosh Island on their coastal migration north, and resumed in November during their migration south. Pods of humpback and gray whales may have remained in the area all summer (Huelsbeck 1994), permitting whale hunting to occur from early spring through the fall.

The killing of whales was the prerogative of titled men among the Makah Tribe (Swan 1870), largely because of the necessary elaborate rituals associated with whale hunting, the cost of outfitting an expedition, and the authority needed to assemble a crew (Drucker 1951). The success of the hunt relied upon the whalers' strict observance of ritual knowledge, which only the elite possessed and which the Makah Tribe believed to be the essential basis of a whaler. Knowledge of and adherence to the rites, along with spiritual assistance received through prayer to the ancestors, was reflected in a chief's wealth. Thus, in Makah theory, the rituals were responsible for one having wealth, and wealth demonstrated the presence and efficacy of a man's spiritual power. Wealthy men married the daughters of powerful chiefs, perpetuating the presence

of an elite class and, by selecting spouses from other communities, creating a social and economic network through which wealth, people, and information passed. Drucker (1951) describes the Nuu-chah-nulth groom's harpooning of the door of the bride's house during the marriage ceremony, using an imitation whaling harpoon, complete with floats. The association of whaling with wealth and rank was also evident during marriage ceremonies such as one witnessed at Neah Bay in the 1850s, when the groom's party reenacted a whale hunt upon arrival (Hancock 1927).

In preparation for hunting, Makah whalers trained themselves to acquire spiritual strength and power so that the whale could be killed more easily. Training consisted of ritual bathing, praying, rubbing the skin with boughs or nettles, and imitative performances. Such practices took place at selected, secret locations that were regarded as spiritually powerful places, some of which included elaborate shrines adorned with carved figures and human skulls said to represent the whaler's ancestors (Waterman 1920; Gunther 1942; Drucker 1951; Jonaitis 1999). Each family or extended family had its own secret spot, usually no larger than a room, but kept private from all other families. Even the details of the bather's costume, the prayers, and the type of branches the whaler used were private knowledge that was passed from one generation to the next according to the rules of inheritance. The absence of centralized dogmatic control of spiritual and ritual practices was characteristic of Makah society. Thus, the practices described as general to the Makah in this document and recorded by anthropologists and other early observers may have been the practices of a particular extended family group, because ritual practice varied from family to family. The widow of one Makah whaler recalled how her husband visited a specific place immediately before the hunt and his training continued throughout the whaling season to be ready whenever whales were sighted (Gunther 1942).

Chiefs had two methods of obtaining whales: either hunting them from a canoe on the open water and harpooning them, or using ritual to entice them to die and float ashore. A focus of the whaler's ritual activity at his shrine was to entice the whale to relinquish its spirit and allow its body to drift ashore, thereby permitting the chief to avoid the dangers of hunting at sea (Drucker 1951; Jonaitis 1999).

The whale had a special relationship to the noblewomen and, during the hunt, the whaler's wife would act as if she had become the whale. Her movements would determine the behavior of the whale—if she moved about too much, the whale her husband was hunting would be equally active and difficult to spear; if she lay quietly, the whale would give itself to her husband. Towing chants often reflected this association, and the whalers addressed the dead carcass using a term

that refers to a chief's wife. His wife greeted the whale when the hunters towed the carcass to shore, and she led the procession to the chief's house (Drucker 1951). This transformation that occurs during the ritual (i.e., noblewoman becoming a whale) has an empirical connection, as the presence of the whale in the village validates the chief's spiritual power, authority, and wealth, including his bond to noblewomen who are themselves descendants of great whalers (Gunther 1942; Drucker 1951).

Hunting crews were led by the titled nobleman who owned the 30-foot (9.1-m) cedar canoe and its specialized equipment and acted as harpooner. There were typically seven other crew members, including a steersman and six paddlers, one of whom was also a diver who fastened shut the whale's mouth after it had been killed. Each of the eight-man crew was physically fit and either possessed hereditary access to the position and its complementary ritual knowledge or obtained such knowledge through a supernatural encounter (Curtis 1916; Waterman 1920). Each man dressed in special skin clothing adorned with feathers (Sapir 1910 to 1914). A number of canoes hunted together, each outfitted with harpoons, sealskin floats, harpoon lines of whale sinew and others of cedar, and a variety of knives (Waterman 1920). Several ethnographic reports containing information based on accounts from whalers have described the hunt (Curtis 1916; Drucker 1951). In one hunting strategy, lookouts were stationed at coastal high points to alert hunters of the presence of a whale. When a whale was sighted from shore, the Makah hunters set out in previously equipped canoes that were kept ready for use. Whales could often be observed close to Umatilla Reef and Swiftsure Bank, near the entrance to the Strait of Juan de Fuca, where the migrating whales would be feeding. A hunt could last for several days and take the hunters far out to sea, a journey that required considerable navigational skills (Waterman 1920).

Curtis' (1916) description of the hunt conveys some of the hunters' specialized knowledge and finely tuned skills that were the necessary complement to the rigorous spiritual training each hunter endured. Yet there was likely no skill more important than that of the chief who wielded the immense harpoon and, only several feet from the whale, thrust it into the flesh of the submerging prey, after the whale's flukes went underwater and could not upset the hunters' canoe. Once harpooned, the Makah hunters threw several other harpoons into the injured animal, until it was finally exhausted. Then the whale hunters began singing to the whale, imploring it to head shoreward as they started the arduous task of towing home their immense catch. When the hunters followed the prescribed rituals, the whale spirit left the body of its host, and the hunters successfully towed the whale to the chief's village for butchering. As they traveled, the hunters

continued to sing chants encouraging the whale to move to shore (Curtis 1916; Waterman 1920; Drucker 1951).

First Beach, situated next to Neah Bay, was where the headman towed his whale for flensing. It was known in the Makah language as *čiˀ·ʔawa·ʔiyak*, "place for butchering whales." Renker and Pascua (1989, no. 190) listed this site as a traditional cultural property retaining significance to the Makah Tribe. Other chiefs towed harvested whales to beaches closer to their villages (Subsection 3.9.3.3, Other Culturally Important Sites).

The villagers hauled the catch as high on the beach as possible. In some communities, all the village children helped pull the whale the last few yards (Drucker 1951). Butchering procedures depended on the species, but ritual and ceremony always accompanied the initial steps as an elderly whaler made the first cut into the whale, now decorated by the Makah with eagle feathers and white down taken from waterfowl, and the men began to strip away square slabs of the valuable blubber. The dorsal section, richest in oil, was reserved for the chief hunter, though he is reported often to have sold or given it away. Choice morsels were reserved for the hunters and for those leading men who had rights to particular pieces of the whale. The chief whaler, dressed in ceremonial gear, also entertained the villagers with his songs and imitations. He provided the villagers with freshly cooked blubber from his catch and distributed the remainder. The villagers, in turn, sang songs honoring the chief's and the whale's prowess and generosity. For as many as four nights, the chief led the community in ceremonial performances marked by imitations of the whale, the hunt, and songs that praised the whale. Individual whalers owned different songs (Swan 1870; Waterman 1920). Drucker (1951) noted that the Nuu-chah-nulth carried the concept of ownership to "an incredible extreme," with the result that all ceremonial privileges, such as the right to use certain songs and dances, perform certain rituals, or certain acts within them, were owned property.

The Makah probably regarded the whale as a guest in the village in the same way as the Nuu-chah-nulth of Vancouver Island. Thus, once the community had feasted, the hunters had to return the whale's spirit to the sea by casting small pieces of flesh and blubber into the ocean where it could not wash up on shore (Curtis 1916). The whale carcass was then left for the villagers to help themselves (Drucker 1951). This activity was shared by "the entire tribe, great and small, male and female," according to one observer in the 1850s (Hancock 1927), after which the birds and other scavengers picked at the remains on the beach (Waterman 1920). Thus, once the chief had directed the removal of all the blubber, to be eaten fresh or rendered into oil, the villagers took most of the flesh, also for consumption, in addition to the bones and baleen, as needed.

Drift whales—those whales that drifted to shore after death—were reported to the beach owner by messengers who were paid for the find. The drift whales were examined to identify any signs of ownership, indicated by specific marks on any harpoon heads embedded in the whale's flesh or on seal skin floats attached to the harpoon. Whales that had been identified as lost after being harpooned, or that had been cut free when bad weather threatened the hunters' return home, belonged to the hunter unless another chief's mark was identified. The villagers would congregate on the beach to strip the whale's blubber for their respective chief, after which the people would help themselves to the meat and blubber, again leaving the carcass with most of the bones (Drucker 1951).

Meat that was decayed, which sometimes occurred with drift whales, or whales caught too far from shore on which the flesh began to rot, was left on the beach along with the bones. The villagers took the bones from the beach only when they could serve some purpose; thus, the skeleton with any remaining morsels of meat remained on the shore or was washed out to sea (Waterman 1920; Drucker 1951). Blubber, however, seldom deteriorated to the extent that it could not be used, if only for technological purposes, and it was not consumed (Waterman 1920; Drucker 1951).

Whale products provided enough blubber and oil for the village, as well as a surplus of oil to be traded with neighboring tribes (Huelsbeck 1988). An account of exchange included in the journal of John Jewitt, a crewman from an American vessel taken captive by the Nuu-chah-nulth chief Maquinna in 1803, noted that Maquinna's trade with neighboring tribes was "principally train oil," and from the Makah he received "great quantities of oil" and whale sinew (Jewitt 1993). The oil was stored in boxes specially made for the purpose or in bladders or stomachs of marine mammals and certain large fish (Curtis 1916). Whale oil was a standard condiment served with meals, typically used as a dip for dried foods such as salmon and berries (Drucker 1951). Whale oil was also thrown on central fires to fuel the blaze during rituals, and at least one visitor to the area in the mid-1800s observed shell lamps in which whale oil was burned (Drucker 1951). The Makah Tribe made offerings to the supernatural world by burning feathers and whale oil, an act accompanied by prayers from the head of the household (Curtis 1916). In the 1840s, Makah traders provided whale oil to the Hudson's Bay Company's Fort Victoria for shipment to England (e.g., Fort Victoria Journal, December 7, 1846). Additionally, Makah craftsmen used bones and baleen as raw material for tool manufacture and bones as building material (Huelsbeck 1994).

The ethnographic literature is inconsistent regarding the consumption of whale meat, the dark flesh found under the thick layer of blubber (Waterman 1920). Stories recorded by Edward Sapir

in the early 1900s tell of Nuu-chah-nulth villagers boiling fresh whale meat, drinking the broth (Arima et al. 2000), and giving feasts of meat and blubber (Sapir 1910 to 1914). Drucker (1951) confirmed Curtis' (1916) earlier report that the whale flesh could be both sun and smoke dried, although statements by Drucker's Nuu-chah-nulth consultants indicate that the meat was dried in smaller quantities than the valuable blubber. So rich was the partly dried blubber that pieces of it were given to suckling newborns until the child's mother could produce enough milk, generally by boosting her own nutrition with extra servings of blubber (Curtis 1916). Swan (1870) reported that only the vertebrae and offal were left unused. Among the whale bone artifacts recovered from the Ozette site are spindle whorls, bark shredders and beaters, cutting boards, clubs, wedges, and tool handles (Huelsbeck 1994). Drucker (1951) also reported the historic use of whale bone for such implements.

Historical and ethnographic accounts provide only rough calculations of the numbers of whales taken annually. The catch of 15.99 and 36.9 tons of blubber was reported and likely a similar amount of meat, depending upon whether the whales were Pacific grays or humpbacks, respectively (Huelsbeck 1988). Another source, writing specifically of the Makah Tribe, estimated that an average whaler might take one or two whales a year but that a skilled and fortunate hunter might catch as many as five in the same period (Densmore 1939). This is a higher estimate than the numbers harvested between 1889 and 1892 when the entire Makah Tribe (including all whalers) averaged 5.5 whales a year (Huelsbeck 1988).

Reassessments of the role of whaling in indigenous society indicate that whaling had great economic significance (Huelsbeck 1994) and was not simply a "symbol of chieftains' greatness," with "little economic importance," as anthropologist Philip Drucker (1951) once described whale hunting, in light of the few whales caught by Nuu-chah-nulth men he interviewed in the mid-1930s. Ceremonies, music, and dance associated with this occupation, based on chiefly ownership and rank, held a central role in the maintenance of the Makah social system. A titled family maintained its standing by hosting ceremonies, particularly intervillage potlatches, performing hereditary songs, displaying owned prerogatives, and giving away food and gifts, all of which required great wealth. Even before a successful hunt, whaling chiefs held potlatches at which they made gifts of sticks said to represent strips of blubber to be given at a later date (Drucker 1951). The hereditary privileges owned by whalers and displayed at significant events were games and songs associated with the whale (Goodman and Swan 2003), among them a performance in which the dancers wore gear and imitated the motions of a whale (Densmore 1939).

3.10.3.4.1 Cessation of the Hunt

Historical and ethnographic records indicate that the Makah Tribe hunted whales until the 1920s when this practice went into abeyance. However, this period represented the conclusion of a gradual decline in whale hunting that had taken place since the 1855 Treaty, when 30 Makah canoes hunted together, and each canoe was said to have processed 1,000 gallons (3,785 L) of oil (Swan in McDonald 1972). Swan (1870) noted that, even in the 1850s, the Makah Tribe was whaling less than in the past, but he could provide no clear explanation for the decline.

An account of one of the last Makah Tribe whale hunts was reported to the *Victoria Daily Colonist* in 1905, largely because of the observer's fascination with the Makah Tribe's use of new technology for whaling. In that hunt, 60 Makah hunters in six large canoes stalked a whale. Once the main harpooner hit the prey, his fellow hunters thrust a large number of iron-tipped harpoons into the injured animal. A steam-powered commercial tow boat then pulled the whale into Neah Bay for butchering (cited in Webb 1988).

By 1916, Curtis (1916) observed that the Makah Tribe had recently revived the practice of whaling. It is clear, however, that the hunt had been untenable for a number of years and had ceased completely by the 1920s. Social, economic, and biological factors all contributed to the Makah's cessation of the hunt. It was not the first time that the Makah Tribe interrupted a marine-based occupation. Makah witnesses appearing before the British Commissioners investigating the pelagic fur seal industry in the 1890s reported "for about twenty years the hunting was practically given up" because of the loss of lives at sea while hunting (cited in Crockford 1996). The Makah Tribe resumed this activity in the early 1900s when conditions improved.

Research by Jennifer Sepez (2001) reveals that some Makah families continued to use whale meat and oil after the 1920s, when the hunt was discontinued. However, Sepez hypothesized that the likely source would have been from beached whales, whales caught in fishing nets, or possibly aboriginal whale hunts that continued to occur in Canada in the 1930s. At this time, British Columbia canneries sometimes processed whale meat obtained by aboriginal hunts (Webb 1988).

3.10.3.4.2 Factors Responsible for Discontinuation of the Hunt

Robert L. Webb's (1988) history of commercial whaling documents a steady decline in all species of whale that became the target of commercial whalers. Historical evidence indicates that whaling in the lagoons of Mexico and Baja California in the 1840s and the shore-based commercial whaling that began off the California coast in 1851 significantly reduced the once-healthy stocks of migrating ENP gray whales along the western coast of Washington. One observer estimated that, around the mid-1850s, 1,000 whales could be seen each day between

December and February making their southern migration, suggesting to Scammon (1874) that whales migrating along the coast of California likely numbered about 30,000 a season. When Charles Scammon published his first edition of *The Marine Mammals of the North-Western Coast of North America* in 1874 only 20 years later, he estimated that the number of migrating gray whales did not exceed 10,000 whales.

With the development of the darting gun around 1870, which replaced the iron harpoon hurled by manual strength from the bow of a whaleboat, it became possible for commercial whalers to kill humpback whales (Webb 1988). This placed the industry in direct competition with the Makah Tribe, who hunted this species along with the gray whale.

The new whaling methods included steam-powered chaser boats on the sea and oil-fired steam rendering plants on shore, making easier, faster hunts possible and providing diverse new products from the raw materials. Although whale oil now competed with less costly petroleum products and vegetable and mineral oil, new ways of processing the oil kept it in demand and facilitated a renewed interest in whaling on the northwest coast in the early 1900s (Webb 1988). Humpback whales found in inlets and bays were hunted, along with blue and fin whales, and a new factory-ship technology permitted a resurgence of the gray whale hunt. Over a 10-year period, whale stocks dwindled. Thus, when the Makah Tribe and their Nuu-chah-nulth neighbors on Vancouver Island attempted to hunt whales in the early 1900s, few whales remained in the local waters (Webb 1988).

When World War I began, the government urged the public to consume whale meat without much success, as most Americans did not have a taste for the meat, although it appears that the Makah Tribe continued to enjoy it and consumed some whale meat processed by Canadian canneries (Goodman and Swan 2003). By the 1930s, with whale stocks almost entirely depleted, the whaling countries began to recognize the need to control the numbers of whales being taken. At a London conference in 1937, member countries adopted the International Agreement for the Regulation of Whaling, which applied stringent controls on the numbers and species of whales being killed. The gray whale became protected, along with right whales (except for a few taken by permit), by those countries participating in the agreement (Webb 1988). Commercial hunts depleted stocks of humpback whales as well, but international agreements did not protect this species until 1965 (Webb 1988).

In addition to depletion of whale stocks, the Makah's increasing involvement in the pelagic fur sealing industry also contributed to cessation of the Tribe's whale hunt. The skills that made the Makah successful whale hunters also made them valuable participants in the pelagic sealing

industry of the nineteenth century. This commercial industry was an outgrowth of the Makah Tribe's aboriginal subsistence and fur-trade sealing efforts. By the 1860s, commercial sealing substantially relied on a Makah wage-labor force with the knowledge of navigation and watercraft needed to succeed at sealing. The shore-based hunt was considered dangerous as the hunters followed the seals far from land in open canoes. In 1865, the Indian Agent at Neah Bay began chartering schooners to assist the Makah in their offshore hunts (Lane, cited in Crockford 1996). By the mid-1870s, the schooner owners benefited from the near-abandonment of the Makah people's shore-based seal hunt, as more men signed on to work from schooners and hunt seals (Crockford 1996).

The pelagic seal hunt relied upon certain elite tribal men continuing in their role as administrators of community economic activities. Whereas these men formerly organized the harvest and distribution of local resources, they now organized crews for the schooners. However, the more equitable distribution of the proceeds equalized the relative ranking of the participants, as the trade economy elevated the resource beyond the level of subsistence and put greater wealth directly in the pockets of crew members (Crockford 1996; Goodman and Swan 2003). Commoners were now ostensibly equal to chiefs, with opportunities available to them as individuals. Thus, the titled class could no longer expect the privileges that whaling had helped them maintain, except in ceremonial potlatches and social networks. By 1875, sealing for furs was the Makah Tribe's chief form of income. By 1893, Makah tribal members owned 10 sealing schooners. These vessels earned a healthy income for their owners but set these men apart from those who did not share in the profits of the new economy. Eventually, over-harvesting and government regulations led to diminished profits and, ultimately, the end of the seal hunting industry. In 1897, the U.S. Government signed an international convention that effectively banned pelagic seal hunting by its citizens, and the once-successful Makah hunters were left waiting for compensation for their lost business, which they believed had been secured to them by treaty. As late as 1957, Murray (1988) reports the Makah Tribe was still appealing to Washington for payment as a result of losses incurred because of the 1897 law and the seizure of a Makah sealing schooner operating in Alaska. Shooting harbor seals for food continued through the 1990s, long after the hunting of fur seals ceased, as seal oil provided the Makah Tribe with fat that was rendered into oil and used as a condiment (Sepez 2001).

Government agents among the Makah Tribe made considerable, yet ineffective, efforts to promote self-sufficiency through agriculture on the reservation. Some agricultural opportunities became attractive to the Makah Tribe, especially because crop production provided cash, was

open to all members of society, and, in the case of the hop and berry fields, permitted families to remain together while they worked as wage laborers. Unlike occupations such as sealing, in which only men were hired, and several Makah men became affluent, whole families could be employed on farms for low wages. Government agents also encouraged Makah children to adopt new values introduced through Christianity and education. In the 1870s, the U.S. Government made potlatching, bone games, and other ceremonial activities illegal, as these activities were regarded as primitive and backwards, resulting in the Makah Tribe's loss of hosted occasions that advanced and recognized the status of leading whaling families (Goodman and Swan 2003). By the early 1900s, the Makah Klukwali (wolf ceremony) and Tsayak (curing ceremony) secret societies involving dramatic reenactments that had been performed by such families, had faded from public view (Goodman and Swan 2003). These secret societies either relocated to offshore islands or adopted a European-like façade to avoid interference by American authorities.

Another direct effect of government policy occurred in 1879 when the first election of chiefs or headmen took place at Neah Bay, followed by elections in the other Makah communities (Goodman and Swan 2003). It is likely that the community elected men of high rank, thus undermining the Indian agents' efforts to equalize the position of all Makah tribal members. Introduction of the dominant American society's values, including the ideal of equality among all persons, was an expressed goal of U.S. Government Indian assimilation policy in the late nineteenth century (Goodman and Swan 2003). Yet the Indian agents' attempts to displace the authority, and consequently diminish the acquisition of wealth that accompanied chiefly positions, including that of the titled men who once carried out the whale hunt, took its toll on the community's recognition of traditional leadership. In the absence of the hereditary system, disagreements arose among those still claiming chiefly descent who expected recognition of the rights that flowed from these inherited positions (Goodman and Swan 2003). Despite changes in leadership positions, Makah families of high status kept alive some of the practical and ritual knowledge associated with the whale hunt, even in times of inactivity, although the relative influence of these families within the community declined with the changing economy (Drucker 1951; Goodman and Swan 2003). Drucker found similar retention of whaling knowledge among the Nuu-chah-nulth (1951). In the mid-1930s, he found that the chiefs of one group passed down "both ritual and practical features of the [whaling] complex" to four generations without whaling, before their resumption of the hunt. According to Renker (2012), this transfer of whaling knowledge within Makah families has continued to the present day. The Tribe's 2012 needs statement explains:

> . . . the Makah desire to reinvigorate the whaling tradition never dissipated. Households took advantage of drift whales for food and materials before federal communications and supervision began to prohibit this practice. Families pass on whaling stories, traditions, songs, and secrets from generation to generation. Whaling designs and crests still decorate public buildings and private homes. Makahs proudly display historical photographs of their whaling ancestors in their homes, and the public school on the reservation exhibits whaling artifacts and photographs. Accounts of Makah whalers are read again and again in school and homes. Whaling displays in the Makah Cultural and Research Center and other museums keep visual scenes in the heads and hearts of Makah people (Renker 2012).

3.10.3.5 Contemporary Makah Society

Several post-contact factors (i.e., influences brought about after the arrival of the first Europeans in the late eighteenth century), including epidemic disease and mandatory schooling, resulted in consolidation of the five traditional villages into the single community situated at Neah Bay where most of the on-reservation Makah population now resides. The Neah Bay community primarily consists of single-family dwellings, including mobile homes and Housing and Urban Development houses, with housing for seniors located in the center of the village across from the Senior Citizens Center. The churches, schools, public health facilities, Makah Cultural and Research Center, and a large community center, where revived potlatches, bone games, and other community functions are held, are located in the community of Neah Bay.

Since 1931, Neah Bay has been connected with communities to the east on the Olympic Peninsula by road, although Makah life remains oriented to the sea. Subsistence and commercial salmon and halibut fishing have remained central to the Makah economy, especially after the cessation of the pelagic sealing industry at the end of the nineteenth century, because of the reservation's proximity to some of the biggest halibut fisheries on the Pacific coast (Colson 1953; Sepez 2001). From the 1950s through the 1970s, Makah men worked as loggers cutting timber from the reservation and nearby hills (Colson 1953).

The Makah Air Force Base, established in the area in the 1940s, closed in 1988. Its facilities are now occupied by tribal agencies and Tribal Council offices (Goodman and Swan 2003). Notwithstanding personal preference, a chronic housing shortage at Neah Bay now requires some tribal members to live in neighborhoods outside of Neah Bay, specifically Wa'atch, Baadah, Pacific Beaches, Diah't, and a housing development at Eastern Bayview (Sepez 2001).

The lineage group, or Makah family, is the fundamental element of contemporary intratribal identity, according to Sepez (2001), who notes that it is also the basic social unit in which cultural traditions are passed between generations. Families hold divergent views of tradition, especially in spiritual and ceremonial activities, but also in the types of natural resources harvested and the amounts consumed. Most households, however, consume local subsistence foods during the year (Sepez 2001).

Logging that sustained the community relatively prosperously in the mid-twentieth century has now declined, although the Tribe operates Makah Forestry Enterprise, an expanding company engaged in forest management both on and off the reservation. Fishing, which had also declined, is now providing a higher total income than in the recent past because of the development of trawl fisheries. Apart from these industries and a few small business enterprises, government is the largest employer in the area. Makah tribal members no longer work in agriculture, because the hop and berry fields of western Washington turned into residential areas. Tribal artists produce jewelry, silk screen prints, and clothing with aboriginal designs for sale in local shops.

In response to the 1934 Indian Reorganization Act, the Makah Tribe wrote a tribal constitution and created the Makah Tribal Council, which replaced the former system of chiefs as the daily political arm of the Makah Tribe. Any enrolled member of the Tribe who resides on the reservation is now eligible to run for office, regardless of the class, rank, or status of particular ancestors (Goodman and Swan 2003). Other government policies were also reversed by the 1934 statute, particularly the previous practice of allotting tribal land to individuals. The act also supported Indian religious freedom and promoted a revival of Makah culture (Goodman and Swan 2003). Congress enacted the American Indian Religious Freedom Act in 1978 to further protect and preserve American Indians' inherent right to freedom to believe, express, and exercise their traditional religions (Trope 1994). This act was followed the next year by the Archaeological Resources Protection Act of 1979, which specifically mandates that the American Indian Religious Freedom Act be considered in the disposition of archeological resources. Subsequent legislation, the Native American Graves Protection and Repatriation Act of 1990, mandated the return of Makah and other tribes' sacred objects, objects of cultural patrimony, human remains, and associated funerary objects from federal agencies and federally funded museums (and universities) (Thornton 1994).

Makah Days, initially started in 1926 to celebrate the extension of American citizenship to American Indians, have evolved into a major 3-day event held each August. The event celebrates Makah culture and attracts hundreds of visitors, both aboriginal and non-aboriginal. Months of

community preparation culminate in a cultural festival highlighting traditional foods, dancing, singing, and games, in addition to more contemporary events such as a parade, fireworks, and sporting events (Tweedie 2002). For this occasion, families share their less prestigious songs and offer training in dancing to non-family members. The songs and dances are used for public performances that, along with displays of athletic excellence, generate feelings of Makah solidarity in friendly opposition to other tribes, reinforcing the Makah Tribe's identity (Bates 1987).

Traditional Makah ceremonials that had declined by the 1950s have had a resurgence, beginning in the 1960s, because of the diligence of a small group of elderly Makah women who were well trained as children and retained knowledge of ceremonial affairs. They guided a new generation of Makah tribal members who valued the cultural traditions of their people and began hosting community events (Goodman and Swan 2003). This coincided with the archaeological recoveries at the ancient Ozette site, which provided a material foundation for the revitalization of cultural activities. The Ozette investigations provided an important impetus for renewed respect of and interest in the knowledge of Makah elders who worked cooperatively with archaeologists in identifying artifacts. These individuals also provided the necessary guidance to establish the Makah Cultural and Research Center, a tribally owned and operated institution committed to the support of Makah cultural activities and the interpretation of the Ozette artifacts (Erikson 2002). The Makah elders decided to showcase the hunting of whales and seals in the Makah Museum's displays (Sepez 2001).

A number of clubs devoted to cultural activities also began in the 1950s and 1960s, including the Makah Club, the Sla-hal Club, the Makah Arts and Crafts Club, the Hamatsa Club, the Makah Canoe Club, and the Warrior's Club (that honored tribal members who served in the United States military). The re-valuation of Makah traditions that occurred during this time provided an impetus for families to bring out songs and dances that had not been performed in decades (Erikson 2002). Federal funds made supplementary cultural programs possible, including a comprehensive summer program with funds for elders to develop classes in traditional crafts, music, and the Makah language (with a Makah language K through 12 program in the schools) (Erikson 2002). The resurgence of these programs has provided new outlets for Makah traditions; community events are now common occasions for singing and dancing, and the museum provides ongoing educational programming (Erikson 2002).

Potlatching increased in the 1960s, along with the resurgence in cultural awareness. Among the Makah tribal members, this activity appears to fluctuate with economic times. When better

economic prospects returned with an improved United States economy in the 1990s, several families hosted potlatches, some costing as much as $15,000 per ceremony (Goodman and Swan 2003). Ceremonial affairs may lack the complexity of former events, Goodman and Swan (2003) observe, yet many potlatch elements described in the nineteenth century can still be seen today as singers perform family-owned songs, young people receive ancestral names, guests participate in group dances, and the hosts serve great quantities of traditional native foods. Many of these songs and dances are those passed down among high-status whaling families and are used to publicly display their family wealth gained and maintained through generations of whaling.

For traditionally minded Makah, a spiritual life is tied to the lands and waters of their territory; remote places devoid of human activity where private cleansing rituals can take place without intrusion, and initiates can draw near to the supernatural part of the world. Individuals perform rituals and seek proficiency in whatever endeavor they undertake by strengthening their relationship with particular spirits (Drucker 1951). The arduous requirements of whaling have led to the rejuvenation among some Makah hunters of whaling rituals, which are based on private family knowledge (Braund and Associates 2007).

3.10.3.5.1 Makah Whaling

The cultural role of whaling is demonstrated in the archaeological record and in the ethnographic accounts of the twentieth century that have been summarized above. These published accounts now supplement the Makah Tribe's oral traditions as they prepare for the contemporary whale hunt and consider past traditions for future manifestations of their culture. Many traditions related to whaling have waned, however, since the Makah Tribe's cessation of the hunt in the 1920s. Nevertheless, some of those individuals taking a leading role in revitalizing this occupation are from whaling families who trace their ancestry to men who formerly hunted whales (Tweedie 2002). At the same time, the Makah Tribe is actively revitalizing its language and cultural traditions. According to Renker (2012), "Makah people had never stopped educating their children about their respective familial whaling traditions." Furthermore, the public school included a whaling curriculum, and the Makah Cultural and Research Center supported whaling education efforts. Renker (2012) noted, "While non-Makahs perceived a large temporal gap in the whaling history of the Tribe, tribal members saw continuity. Many individuals were patiently waiting for the whaling traditions to be taken from storage and implemented in reality."

The day in 1997 that the IWC acted on the United States' request on behalf of the Makah Tribe was marked on the Makah Reservation with celebrations, including giving tribal employees a half-day off and 30 local vehicles forming an impromptu parade, some of the cars and trucks

appropriately decorated and horns blaring. An anthropologist observing the event later wrote, "It seemed that the entire village lined the parade route" (Tweedie 2002). The celebration continued the following week with a community potlatch at which tribal singers performed victory songs.

The Tribe sought to measure community opinions about whaling and involvement in the 1999 hunt in household whaling surveys conducted in 2001, 2006, 2011, and 2017 (Renker 2018). Surveyors canvassed the opinions of 32 percent of the on-reservation households concerning their views on the Tribe's resumption of whaling (Table 3-37). The expressed purpose of the survey was to better understand the opinions of tribal members about whaling hunting and related activities (Renker 2018). Anthropologist Ann Renker Ph.D., who since 1980 has worked with the Makah Tribe, designed the surveys with input from the Makah Cultural and Research Center. Dr. Renker also analyzed the results of the surveys, administered by a team of trained Makah tribal members.

For the 2001 survey, 217 households of enrolled Makah tribal members were randomly selected and contacted for the study, and 159 households agreed to participate. Four selected household heads who had publically opposed the hunt declined to participate in the survey. The survey instrument for each of these individuals was marked negative for all questions regarding support of the hunt or use of whale products and, thus, was included in the tabulation of results representing the views of 163 households. All respondents were at least 21 years old and enrolled Makah tribal members residing on the reservation. The respondents' confidentiality was maintained by using numbered surveys, keyed to a master list of households used for administration purposes, but not released to Dr. Renker during her analysis of the results. All three surveys had results that differed in some respects but were substantially similar in others.

Table 3-37. Makah Attitudes Toward Whale Hunting.

		Year			
		2001	2006	2011	2017
Number of Respondents		159[72]	152	170	168
Should the Tribe continue to whale hunt?	Yes	95.6	88.8	94.1	95.8
Motivation for support?[73]	Treaty Rights	46.1	40.8	37.6	94.1

[72] Four tribal members surveyed in 2001 declined to complete the surveys. The percentages report the percentage for each answer based on 159 respondents, except the question about support for the hunt, which counts the four as "no" responses, for a total of 163 respondents.
[73] Respondents could choose multiple answers; therefore, totals can exceed 100 percent.

	Diet/health	35.5	26.3	15.9	24.7
	Restore culture/tradition	36.2	44.1	56.5	-
	Spiritual benefits	20.4	-	-	-
Is the whale hunt a positive force for the Tribe?[74]	Yes	96.2	79.6	85.2	-
Would you like to have more access to whale products in the future?[75]	Yes	91.2	80.2	90.6	-
Have you or a member of your household engaged in ceremonial whaling activities since 1999?	Yes	28.3	42.2	23.8	39.9

Sepez (2001) also concluded that many tribal members desire whale products, with 73 percent of households planning to eat whale obtained from future hunts. Some household members clarified that, while they would not cook whale products themselves, they would consume whale if it were served at community feasts.

In the 2001 survey, 79 percent of the survey respondents reported that they watched television coverage of the whale being taken. A larger number, 81 percent of the 163 respondents, met the hunters on the beach when the whale was brought ashore. An estimated 1,400 tribal and non-tribal people witnessed the arrival of the whale and its hunters to Neah Bay. People traveled to Neah Bay from other communities to participate in the festivities and camped or stayed with relatives during festivities associated with the successful hunt (Renker 2002).

When asked about the positive benefits to be derived from continuing the hunt, 52 percent of the respondents reported a correlation between the hunt and a better lifestyle (Renker 2002). They viewed the hunt as a vehicle to reinforce traditional Makah values, such as pride, self-esteem, and male responsibility, in addition to combating the contemporary problem of substance abuse (Renker 2002; Braund and Associates 2007). As preparation for the 1999 and 2000 hunts, Makah whalers reported enduring intense physical and spiritual training, which culminated in a deep bond among whalers (Braund and Associates 2007). Such preparation is considered a private affair among the Makah families (Braund and Associates 2007). In some cases, whalers identified

[74] This question was changed in the 2017 to a self-assessment of the effect of whaling on six categories of Makah life, using a numerical scale of 1 to 10, negative to positive, to score the relative effect of whale on each category.
[75] This question was changed in 2017 to determine how many respondents would like to have more access to specific whale products, such as meat, oil, blubber, and bone.

individuals who underwent major life changes as a result of participating in the whale hunt (Braund and Associates 2007).

As in the past, the killing of a whale is a focal event in which many Makah people are directly or indirectly involved. Table 3-38 lists some of the activities involved in the 1999 whale hunt, with a tally of the numbers or percentages of Makah tribal members involved in each activity, based on data obtained during the household whaling survey and contemporary ethnographic literature (Renker 2002; Bowechop 2004; Bowechop 2005a). Some individuals are counted in more than one category in Table 3-38. Considering that 43 percent of the respondents also stated that the hunt fostered Makah and intertribal unity, the hunt seemed to be a means of bolstering social accord within the community.

Table 3-38. Numbers and percentage of participants in the 1999 Makah whale hunt.

Activity Associated with the 1999 Hunt	Numbers/Percentage of Participants
Members of the Whaling Commission	23 Makah men representing "all major families"
Preparation of equipment, including canoe	2 Makah men, plus Nuu-chah-nulth mentors who built a canoe, and 20 to 25 people making equipment
Training for hunt crew	18 to 20 Makah men
Whale hunt crew	1 canoe (1 head harpooner, 7 men) and 1 chase boat (5 people), all Makah
Towing crew	5 canoes (main canoe and 4 support canoes) and 1 fishing boat; about 60 people, 4 canoes from supporting Northwest tribes
Attendance on beach	1,400 people, mostly Makahs
Butchering	100 people, mostly Makahs
Distribution crew	50 Makahs
Consumption of meat/oil	81 percent of household whaling survey respondents
Attendance at post-hunt community feast	95 percent of household whaling survey respondents; approximately 3,000 people total "Thousands of other friends and relatives joined our tribe."
Attendance at parade	79 percent of household whaling survey respondents; about 400 people total
Participation in post-hunt ceremonials	38 percent of household whaling survey respondents
Use of bones	Approximately 60 school children, mostly Makah
Use of baleen	8 Makah hunters

Source: Bowechop 2004, 2005a.

The hunt, in conjunction with whaling-related discoveries made at the Ozette Village site and establishment of the Makah Cultural and Research Center, also provided the opportunity for the revival of Makah whaling rituals and traditional knowledge after a 70-year hiatus (Braund and Associates 2007). Hunters reported that the spiritual and physical training, the new-found whaling

knowledge and skills gained from the experience, and the activation of inherited whaling customs and attitudes from older Makah tribal members (obtained orally and through the ethnographic collaboration of previous generations) strengthened tribal member identity as descendants of Makah whalers (Tweedie 2002). Tribal members reported that whaling songs and rituals also resumed following the 1999 hunt, with more people participating in family songs and sharing traditional knowledge (Braund and Associates 2007).

Reintroduction of whaling activities also facilitated a specific vocabulary, now mostly in English but some in the Makah language, that encapsulates context-based traditional ecological knowledge that once was widespread in the community (Bowechop 2005a). Without engaging in the hunt, this knowledge lay dormant in the memories of the elders in a few families and in the ethnographic accounts of previous generations. Bowechop (2005a) reports a gradual increase in the attendance of language and cultural classes, with the highest attendance corresponding with the resumption of the whale hunt.

The whale hunt provided new experience-based educational opportunities that went beyond the current efforts of the Makah Cultural and Research Center to recover the language, crafts, and Makah ecological concepts that Sepez (2001) explains are offered in schools and at summer camps and underlie and sustain the elders' ecological teachings. The quest for knowledge relating to the ancient activity of whaling reached beyond the whaling crew and community children, for the majority of respondents in the Makah household whaling survey reported a desire to learn more about preparing whale products and using whalebone. They expressed a willingness to share such information with other Makah tribal members (Renker 2002). Seventy-six percent of Makah households expressed a desire for whale bones, presumably to revitalize certain crafts. The Makah Tribal Council, however, decided to offer the 1999 whale hunt bones to the local public school for a bone preservation project. Instructors taught Makah students how to clean skeletal remains and reassemble the whale skeleton for museum display. Early in December 2005, with the reconstruction completed, the whale skeleton was hung in the Makah Cultural and Research Center. Approximately 60 students participated in this project (Bowechop 2005a).

The trove of artifacts discovered around 1970 at the Ozette Village site (Subsection 3.10.3.1, Makah Archaeological Resources Connected with Whaling) and the more recent participation in the 1999 hunt has allowed residents to experience a connection to the past that would not otherwise have been possible (Braund and Associates 2007). The connection to their whaling ancestors and to the physical environment also renews Makah cultural and historical identity as whalers (Braund and Associates 2007). Renker (2012), discussing the importance of ceremonial

activities and practices related to the whale hunt in enhancing the spirituality of Makah tribal members, wrote "…48.4 percent of HWS [Household Whaling Survey] III respondents share an opinion that a proper whale hunt is linked to the clean/sober, healthy lifestyle that hunters and their families must have, and that these are a critical part of the Makah Tribe's spiritual profile." She also referred to the Makah whale hunt as "a spiritual manifestation of the connection between Makah and their Creator." Renker (2012) later suggested that because the activity of whaling is so closely linked with physical, spiritual, and ceremonial obligations, the lack of whaling, especially after already being reintroduced to Makah people in recent years, is harmful to the spirituality of the Makah Tribe. Renker (2012) wrote the following:

> Now that a quarter of the Makah Tribe's members participate in ancient religious ceremonies, the lack of an active hunt makes it impossible for certain spiritual rituals to be performed. A spiritual void of this nature is devastating for Tribal members.

Dr. Renker's tribal survey found that 81 percent of the respondents consumed whale products (blubber, meat, or oil) obtained from the 1999 hunt and 87 percent would like to have these products available in the future (Renker 2002). Sepez (2001) also quantified the consumption of whale products obtained from the whale taken during the 1999 hunt. The whale provided roughly 2,000 to 3,000 pounds (907 to 1,361 kg) of meat and 4,000 to 5,000 pounds (1,814 to 2,268 kg) of blubber, most of which was consumed at the community potlatch. Community households received approximately 1.8 pounds (0.81 kg) per capita distribution of blubber. Together with the estimated 0.55 pound (0.25 kg) of meat, Sepez calculated that the whale products consumed in 1999 equaled about 2.4 pounds (1.1 kg) per capita.

Members of other tribes attended the community's celebrations in 1999, witnessing the proceedings and sharing food—necessary components of traditional ceremonials by which a group establishes its status with other groups. When the Makah Tribal Council hosted the community potlatch after the 1999 hunt, the individual whalers received public recognition for their proficiency and commitment, and the Makah, as a tribal group, reaffirmed itself as people of wealth and history who maintain a relationship with the resources of their territory (Bowechop 2004). Within the cultural framework of the Makah people, no other activity besides the whale hunt and community feast is considered to embody such powerful metaphoric expression. Symbols are made meaningful through experience and action, and the whale is the Makah Tribe's symbol for cultural pride and independence. The Makah Tribe regarded the hunt as a means to revitalize and transfer its cultural knowledge associated with the activity.

The resumption of the hunt also provided the Makah Tribe with an opportunity to highlight the relationship with the related Nuu-chah-nulth people of British Columbia, Canada. Both engaged in hunting whales and practiced highly complex rituals believed to ensure the success of the hunt. Makah whalers traveled to Vancouver Island for several weeks before participating in the 1999 hunt to learn whaling techniques and traditions from knowledgeable Canadian elders. Some tribal members from Alaska and British Columbia attended the Makah Tribe's celebration of the 1999 kill (Braund and Associates 2007).

In 2006, 6 years after the last attempt by Makah whalers to hunt whales, the Makah Tribal Council commissioned a second whaling survey to gather information about residents' attitudes toward participation in whaling, including the actual hunt, ceremonial activities, and consumption and use of whale products. The 2006 survey was designed to follow the same methods used during the 2001 survey. The results of this survey are discussed in the Tribe's 2007 needs statement (Renker 2007).

Support for Makah whaling remained high in 2006, with 88.8 percent of respondents indicating that they supported the continuation of the Makah Tribe's efforts to hunt whales (Renker 2007). This percentage had decreased slightly since 2001, when 93.3 percent of respondents voiced support for the whaling efforts. However, the percentage of respondents opposing the effort to hunt whales increased by less than one percentage point, to 4.0 percent. The remaining respondents were unsure about whether whaling efforts should continue, citing reasons such as financial burdens on the village because of legal efforts, concerns about "racial animosity" that arose during and following the 1999 and 2000 hunts, and the effect of whaling efforts on fishing quotas and treaties.

Most respondents who supported whaling viewed the whaling efforts as being positive for the Makah Tribe (Renker 2007). They attributed the whaling efforts with helping to restore or maintain heritage and ceremonies, as well as increasing tribal unity and encouraging healthy living among youth.

A high percentage of respondents (80.3 percent) continued to desire whale products for consumption or use. Respondents also expressed interest in learning more about the butchering, processing, and use of whale products (Renker 2007).

One area in which positive responses increased significantly from 2001 to 2006 was in regard to participation in ceremonial activities (Renker 2007). The percentage of respondents participating

in ceremonial activities rose from 25.8 percent in 2001 to 41.5 percent in 2006. Regarding this outcome, Dr. Renker stated the following:

> The HWS II (Household Whaling Survey II) attests that the ceremonial aspects of the Makah whale hunt are once again becoming a standard part of the life of a majority of Tribal members, even when the Tribe is prevented from hunting because of outside legal struggles (Renker 2007).

Dr. Renker conducted yet another survey in 2011 and again in 2017, which is reported in the Makah Tribe's needs statement (Renker 2018). The results of those surveys were similar to previous surveys and are summarized in Table 3-37.

3.10.3.5.2 Makah Subsistence Consumption

An overview and analysis of contemporary Makah subsistence foraging, focusing on hunting, fishing, and shellfish collecting, indicated that the Makah people continue to rely on their U&A resource harvesting areas for a significant portion of their diet (Sepez 2001; Etnier and Sepez 2008). The survey by Sepez (2001) documented the use of approximately 80 species, with most of the diversity concentrated in the marine resources. While the author of the study was reluctant to rank the resources in terms of importance, largely because of the inability of statistics to discern nonquantifiable qualities of resources that make them important, harvesting and consumption patterns did emerge from the data.

Using household surveys from a randomly selected sample as the basis for her analysis, Sepez (2001) found that 99 percent of the households indicated some type of consumption of local resources for subsistence purposes during the study period. Fully 71 percent of households engaged in harvesting resources, while 94 percent received resources harvested by another household, indicating that sharing resources was a common practice among tribal members. Table 3-39 presents the percent of households using local resources obtained directly or through exchange during the 1997 and 1998 study period.

Table 3-39. Percentage of households using local resources during 1997 to 1998.

Food Resource	Percentage of Households (%)
Halibut, salmon, clams, crab	76 – 100
Mussels, deer, elk, gooseneck barnacles, seal, salmon eggs, barnacles	51 – 75
Steelhead, lingcod, olive shells, chitons, octopus, rockfish, smelt, blackcod, herring eggs, grouse	26 – 50
Urchins, lingcod eggs, local cow, petrale sole, trout, tuna, bear, scallop, oysters, sole/flatfish, sea cucumber,	1 – 25

squid, sturgeon, true cod, shrimp, rabbits, abalone, duck, pigeon, skate, sea lion, small gastropods, wolf eel	
Goose, porpoise, sea anemone, sea otter, sea turtle, shark, whale[1]	

[1] Resources currently used but not included in the survey.

Source: Sepez (2001).

Table 3-39 represents reported local use of the resource. The survey found that the widest range of households use marine resources. Further analysis indicated that fish accounted for 55 percent of meat and seafoods in the Makah diet, a figure that highlights the cultural significance of marine resources when compared to the average 7 percent of meat and seafoods that occupy the diet of other Americans (Sepez 2001).

Sepez (2001) concluded in her study of Makah subsistence that the tribal members' preference for fish and other resources produced through subsistence channels was specific to the type of food being chosen, but that several social and economic factors influenced the role of subsistence in the contemporary tribal lifestyle:

- Perception of subsistence foods as free for the taking.
- Link with cultural identity.
- Perception that seafoods taken from other places are unclean or mistreated.
- Pleasure in undertaking subsistence activities.
- Sense of connection to the local environment and to those who used the resource in the past.

Makah members articulated similar statements when asked about their desire for whale products (Renker 2002). According to Braund and Associates (2007), no food is more symbolic of the traditional Makah culture than whale, for its consumption serves as a metaphoric reminder of the wealth, history, and social structure of the community.

On July 16, 1995, a female gray whale was found entangled and drowned in a tribal marine set net salmon fishery in the Strait of Juan de Fuca outside of Neah Bay. NMFS biologists and the tribal fisherman who discovered the whale removed the carcass from the net, and the Tribe butchered the whale for subsistence use before the meat spoiled. The use of the female gray whale for subsistence represents the first time in recent times the Makah Tribe sought to exercise its treaty right to consume whale products (NMFS 1995).

The Tribe's 2018 needs statement provides a detailed account of current health issues present within the Makah's and other American Indians' communities and discusses the potential nutritional benefits of consuming whale products, suggesting that a return to eating whale could

lead to better overall health of Makah tribal members, both physically and spiritually (Renker 2018).

Sharing food in contemporary Makah society, Sepez (2001) observes, is "an accepted and expected aspect of subsistence" and recognizes a traditional obligation for generosity, particularly extended to those in need. Within a complex system of reciprocity and redistribution, sharing bolsters one's status within the community and serves to enact one's tribal identity. Table 3-40 charts the percentage of Makah harvesters who shared part of their gains during the 1997 to 1998 study year. Seal meat and oil emerged as the resources most likely to be distributed during the time of the survey, with all hunters of seal reporting distribution of the meat or rendered oil. Sepez (2001) notes that the resource column lists items in descending order of percent of harvesters giving some portion away.

Table 3-40. Percentage of Harvesters of Each Resource Who Gave Away Some Portion, 1997-1998.

Resource	Percentage of Harvesters (%)
Seal	100
Halibut, black cod, smelt, octopus, clams, salmon, gooseneck barnacles, fish eggs	99 – 67
Crab, elk, mussels, deer, steelhead, scallops, chitons, ling cod	66 – 34
Olive shells, barnacles, rockfish, grouse, urchins	33 – 1
Trout	0

3.10.3.5.3 Symbolic Expression of Whaling

In both traditional and contemporary Makah society, depictions of the whale and the whale hunt are very meaningful. These symbols were once used only on the property of elite members of Makah or Nuu-chah-nulth society and, therefore, appeared on items such as dance screens or curtains narrated visually with images celebrating the lineage's history, memorial posts to commemorate a chief's greatness, twined whalers' hats decorated with motifs of whaling scenes, wooden images used in ceremonials, and small personal amulets or charms imbued with spiritual power (Black 1999). Chiefs have also tattooed whales upon their chests (Koppert 1930). The traditional view is focused primarily on the relationship between humans and whales, the transformation of the whale into wealth, and the physical features underpinning the metaphors of strength, courage, and generosity.

Ethnomusicologist Frances Densmore photographed a dance curtain containing the large image of a thunderbird carrying a whale, along with other images, hanging in front of one of the walls of

the Neah Bay community hall where dances were performed for Makah Days in 1926 (Densmore 1939). James Swan, a New England pioneer who lived among the Makah in the 1860s, was impressed by a painting of a thunderbird on a chief's house at Neah Bay. He recorded the Makah Indians' description of thunderbird as a supernatural giant who killed whales with lightning fish tied around his waist, then carried them back to the mountains to eat (Quimby 1970). According to Janine Bowechop, current Executive Director of the Makah Cultural Research Center, a commonly held Makah belief is that during a time of starvation, Thunderbird brought a whale to the Makah people to eat and then showed them how to hunt whales. The symbolic use of whales within contemporary Makah society continues to be important (as Dr. Renker observed in the Makah Tribe's needs statements submitted to the IWC in 2002, 2007, 2012, and 2018).

Statements made by Makah participants after the 1999 hunt suggest that the contemporary whalers' association with the whale retains some of the qualities described in the ethnographic literature (Tweedie 2002) but the symbolic use of whales and whaling has extended beyond an association of a chief with his wealth to that of the community as a whole. Symbols of this traditional discourse that were rooted in the practice and experience of the elite now inform the contemporary model of tribal self-sufficiency. The cessation of the whale hunt and its associated privately-owned rituals and ceremonials, along with changes in the traditional Makah social organization, resulted in lessening the direct relationship between the whale and the whalers. Subsequent emergence of the whale as a secular image nevertheless represented the loss of a former way of life, one in which physical and mental strength brought glory and wealth to the chiefs and, thus, to the community at large. Whale hunting in the current discourse possesses symbolic properties and qualities that make it a potent vehicle for the strength of Makah identity, sovereignty, and cultural revitalization. Hence, resumption of the hunt, as Janine Bowechop (2004) concluded in her essay, *Contemporary Makah Whaling*, was necessary to help her people become healthier and stronger and to close the gap between the past and the present.

3.11 Noise

3.11.1 Introduction

The following section documents noise-related issues pertaining to the proposed Makah whale hunts. Included are discussions of relevant noise-related policies and jurisdictions, sensitive noise receptors in the human environment, and background noise conditions near the action area. Key parameters for analysis include ambient noise levels in the action area and the distance between sensitive receptors and noise-producing project activities. Refer to Subsection 3.5.3.3, Sensitivity

of Wildlife to Noise and Other Disturbance, for a discussion of the potential for disturbance to wildlife and key wildlife use areas, such as seabird rookeries and haulouts for marine mammals.

Noise is generally defined as unwanted sound (EPA 1971). Sound level is expressed in units called decibels (dB). The dB scale quantifies sound levels relative to a reference point of 0 dB, which is defined as the threshold of human hearing and is roughly equivalent to the sound of a mosquito flying 10 feet (3 m) away. [76] To account for the large range of sound pressures the ear can detect, the dB scale is logarithmic. A 10-dB increase in sound level is perceived as a doubling of loudness. The ear is not equally sensitive to sound at all frequencies or musical pitches; two sounds of equal intensity (i.e., with equal dB values) may be perceived as having different loudness levels if they have different frequencies. Very high-pitched whistles demonstrate the relative sensitivity of the human ear (as compared to the ears of other species) at certain frequencies; dogs readily hear these sounds, but they are nearly inaudible to humans.

Sound frequency is measured in terms of cycles per second, or hertz (Hz). The human ear is most sensitive to sounds in the frequency range of 1,000 to 5,000 Hz. To account for this sensitivity, a process called frequency weighting is often used in sound descriptions. The most widely used system is A-weighting, in which noise in the frequencies of maximum human sensitivity factors more heavily than other frequencies in determining the overall noise level. Decibel values in this system are commonly denoted as dBA. Most noise regulations use the A-weighted scale to define acceptable limits for noise levels. Refer to Subsection 3.11.3.2.2, for information specific to marine noise and Subsection 3.5.3.3.4, Marine Mammals and Underwater Noise, for a discussion of the frequencies at which the ears of marine mammals are most sensitive.

3.11.2 Regulatory Overview

The OCNMS management plan provides no specific direction regarding noise (NOAA 1993). Control of noise is, however, consistent with Sanctuary goals of resource protection and compatible public use. FAA regulations prohibit the operation of motorized aircraft less than 2,000 feet (610 m) above the Sanctuary and within one nautical mile (1.9 km) of the shoreline (see Subsection 3.1.1.1, Olympic Coast National Marine Sanctuary). In addition, USFWS enforces a 200-yard (183-m) exclusionary zone around islands in the Washington Island National Wildlife Refuges to avoid the flushing of nesting seabirds by boat and other vessel traffic (see Subsection 3.1.1.2, Washington National Wildlife Refuges).

[76] Acoustic scientists use different reference pressures for air and water, resulting in underwater readings that are higher than the same energy source measured in air (Bradley and Stern 2008).

The Olympic National Park, under federal jurisdiction, is managed consistent with enabling federal legislation to ". . . conserve the scenery and the natural and historic objects and the wildlife therein and to provide for the enjoyment of the same in such manner and by such means as will leave them unimpaired for the enjoyment of future generations" (National Park Service Organic Act, 16 USC 1). The control of noise by park authorities is relevant to leaving the natural and cultural resources and values of the park unimpaired. Noise control is particularly germane in portions of the park designated as wilderness; this includes the park area along the Pacific Ocean coastline. Specific regulations prohibit the operation of "motorized equipment or machinery in a manner that exceeds a noise level of 60 dB measured on the A-weighted scale at 50 feet (15 m); or, if below that level, makes noise which is unreasonable, considering the nature and purpose for which the area was established" (36 CFR 2.12). The Wilderness Act does not establish noise regulations, but it implies that noise should be minimized in designated Wilderness areas to achieve "outstanding opportunities for solitude" (PL 88-577).

State of Washington noise regulations in WAC 173-60-040 are in effect statewide. Clallam County has separate noise regulations for music only (County Code Chapter 15.30) and is subject to state standards. Maximum permissible environmental noise levels vary, depending on the land use categories of the noise source and the receiving property. Maximum permissible noise levels range from 55 to 60 dBA for residential properties, 57 to 65 dBA for commercial uses, and 60 to 70 dBA for industrial areas. WAC 173-60-050 specifies exemptions from maximum permissible noise levels in certain cases, including the following:

- Sounds created by the discharge of firearms on authorized shooting ranges (exemption applies only from 7:00 a.m. to 10:00 p.m.).
- Sounds originating from forest harvesting and silvicultural activity (exemption does not apply near residential and recreational areas from 10:00 p.m. to 7:00 a.m.).
- Sounds originating from aircraft in flight.
- Sounds created by emergency equipment and work necessary in the interests of law enforcement or for health, safety, or welfare of the community.
- Sounds created by safety and protective devices where noise suppression would defeat the intent of the device or is not economically feasible.
- Sounds created by the discharge of firearms in the course of hunting.

3.11.3 Existing Conditions

The following subsections identify sensitive noise receptors in the action area, followed by a discussion of existing noise levels in the two media of noise transmission (air and water) in the

action area. The discussion in this section focuses on sensitive noise receptors in the human environment. The sensitivity of wildlife to noise and other disturbance is discussed in Subsection 3.5.3.3, Sensitivity of Wildlife to Noise and Other Disturbance.

3.11.3.1 Sensitive Noise Receptors

Sensitive noise receptors include facilities and activities for which excessive noise may cause annoyance, increased stress, loss of business, or other adverse effects. Examples of sensitive receptors include residential areas, hospitals, schools, performance spaces, and businesses. Open space is also noise-sensitive if excessive noise would adversely affect potential recreational use of the space. Nearly all portions of the action area sustain residential or recreational uses, with maximum permissible noise levels between 55 and 60 dBA. Businesses in Neah Bay and the offices of the Makah Tribal Center meet the criteria of commercial property, while timber harvest areas would be considered industrial sites.

3.11.3.1.1 Olympic Coast National Marine Sanctuary

Staff at OCNMS have identified noise as a management issue for the Sanctuary, particularly with regard to disturbance of humans and wildlife (Parrish et al. 2005). Noise associated with aircraft overflights has been identified as a primary concern, but the extent of overflights within the Sanctuary is not known. It is also unclear whether, or how much, disturbance to Sanctuary-protected wildlife results from overflights (Parrish et al. 2005). OCNMS staff report that overflights occur primarily during the summer and that visitor complaints are rare (Parrish et al. 2005).

3.11.3.1.2 Makah Reservation

Sensitive noise receptors on the reservation occur primarily along trails and shoreline areas used for recreation by residents and tourists. Cape Flattery is a Makah Tribe designated wilderness area. South of Cape Flattery, the Pacific coastline is largely wooded; some inland areas are managed for timber harvest. There is little or no human settlement north of Wa'atch Point. The Makah Tribal Center on the north side of the Wa'atch River supports residential, administrative, and commercial uses. Areas farther south include low-density residential development, with several roads near the shoreline. South of Anderson Point to the Olympic National Park boundary, the shoreline is characterized by rocky bluffs and small pocket beaches. Primitive roads and trails provide recreational access.

3.11.3.1.3 Olympic National Park

Within the Olympic National Park, the shoreline is a designated wilderness area accessible only by foot. In most portions of this area, the total number of users is restricted by a wilderness permit system. A trail and boardwalk connect the parking area at Lake Ozette to the shoreline at Cape

Alava and Sand Point. The number of visitors to this area is restricted only by the capacity of the parking lot. Because the coastal shoreline portion of the park is a designated wilderness area, this entire area of the park is a sensitive noise receptor.

3.11.3.2 Existing Noise Levels

The following sections describe the baseline conditions of the acoustic environment in the action area, including atmospheric and underwater noise. Particular attention is given to sources of noise associated with a whale hunt, namely, aircraft (e.g., news helicopters and other aircraft observing the hunt and associated activities), and vessel traffic. Subsection 3.5.3.3, Sensitivity of Wildlife to Noise and Other Disturbance, addresses existing levels of noise and disturbance at marine mammal haulouts and seabird colonies in the action area. Where available, information from the previous hunts is included to provide a background for subsequent analysis of the potential effects of the alternatives.

3.11.3.2.1 Atmospheric Noise

The primary sources of ambient sound in the action area are natural, mostly wind and waves. Natural quiet found in wilderness recreation areas is characterized by the absence of human-made noise, which creates conditions that allow visitors to enjoy the intermittent sounds of animals, wind, water, and other natural sources.

In addition to natural sounds, human activities are a source of noise in the action area. Near Cape Flattery, people hear the Tatoosh Island foghorn. The acoustic environment in the area of the Makah Tribal Center is likely characteristic of residential and small town centers, with ambient noise levels ranging from 50 to 65 dBA. Settings where people congregate, such as commercial areas, school playgrounds, and sports fields, are additional local sources of noise. Throughout the area, the most pervasive noise source is traffic on local roads. Noise from individual automobiles and trucks can range from 70 to 90 dBA. Sirens of emergency vehicles are likely the loudest noise source; they produce noise at approximately 130 dBA at 100 feet (31 m). The occurrence of such noise is infrequent, irregular, and primarily affects areas next to arterial roads. Noise sources associated with active logging operations include chain saws (110 dBA) and other equipment (80 to 110 dBA). Most timber harvest units associated with the Makah logging operations are located away from residences to avoid noise impacts. However, the Makah Forest Management Plan (Makah Tribe 1999) does not mention noise as an issue to be addressed during logging operations.

Another source of noise in the area is airplane traffic, particularly near the three airports in western Clallam County (Subsection 3.13.3.3, Air Traffic). The most heavily used airport in the area is the

Forks Municipal Airport, which receives an average of approximately 40 operations every day (Federal Aviation Administration 2019). Noise from aircraft taking off and landing is unlikely to be a major issue in the U&A, however, because the airport is more than 15 miles (24 km) away from the southern extreme of the U&A. The Quillayute Airport, which has fewer than 20 takeoffs and landings per day, on average, is approximately 9 miles (15 km) away from the southern extreme of the U&A (Federal Aviation Administration 2019). The Sekiu Airport, which averages approximately 2 takeoffs and landings per day, is immediately adjacent to the portion of the U&A within the Strait of Juan de Fuca and approximately 20 miles (32 km) from the Pacific Ocean portion of the U&A (Federal Aviation Administration 2020).

In their study of overflights in west coast National Marine Sanctuaries, Parrish et al. (2005) gathered information about small, private, general aviation airplanes and helicopters. Such aircraft, typically flown by private pilots for sightseeing purposes, have the potential to disturb humans and wildlife by flying low over Sanctuary waters (Parrish et al. 2005). Other types of aircraft that may occur in the area include regularly scheduled tourist flights, such as those provided by National Park tour concessionaires, and Sanctuary-permitted research flights. Military and Coast Guard flights also occur over the area (Parrish et al. 2005). During field studies at Tatoosh Island in the summer months (June, July, and August) of 1997 through 2003, researchers from the University of Washington documented 106 instances in which aircraft violated overflight regulations by flying below 2,000 feet (610 m) within 1 mile (1.6 km) of shore in the Sanctuary. The frequency with which violations occurred ranged from approximately 0.1 to 0.75 per hour (Galasso 2005).

During the previous whale hunts, media helicopters and other aircraft likely created elevated noise levels. The Coast Guard used helicopters to enforce the exclusion zone around tribal vessels actively engaged in the hunt (Subsection 3.14.3.1, Coast Guard). During the successful hunt, three television news helicopters were present throughout the day (U.S. Coast Guard 1999a). No information is available to document noise levels associated with those sources. OCNMS regulations that require motorized aircraft to fly at least 2,000 feet (610 m) above certain portions of the Sanctuary probably limited the effects of aircraft noise on residents and recreational users near the hunt. Only one instance of an aircraft failing to observe these regulations was reported during the previous hunts (Subsection 3.13.3.3, Air Traffic).

Other noise sources associated with the previous hunt included marine vessels used by the whale hunters, protesters, and law enforcement personnel (Subsection 3.13.3.2.3, Marine Traffic During the Previous Hunt). Most hunt-related activities took place well offshore, and vessel noise was

likely inaudible to sensitive receptors in Olympic National Park and OCNMS. To avoid disturbance to resting and breeding birds and marine mammals, the Makah gray whale management plan prohibited the initial strike of a whale within 200 yards (183 m) of Tatoosh Island or White Rock between May and September. All three strike attempts during previous hunts occurred 1 to 2 miles (1.6 to 3.2 km) offshore (NMFS 1999). Increased vessel traffic was likely audible to local residents near the marina and Coast Guard station at Neah Bay and at Clallam Bay, where most protest vessels moored.

3.11.3.2.2 Marine Noise

Marine environments can be noisy. Natural noise sources include wind, waves, precipitation, earthquakes, lightning strikes, and surf. Biological sounds include whale songs, dolphin clicks, fish vocalizations, and the clicking of crustaceans (Urick 1983; National Research Council 2003). Noise sources associated with human activities include commercial shipping, geophysical surveys, oil drilling and production, dredging and construction, sonar systems, oceanographic research, acoustic deterrent and harassment devices, and power turbines (National Research Council 2003; Nowacek et al. 2007; Hildebrand 2009).

Open ocean ambient noise levels estimated from sound data collected in portions of the South Pacific with relatively low levels of human activity suggest that low-frequency sound levels range from 40 to 50 dB (relative to 1 microPascal at 3.3 feet (1 m)[77]) in calm seas (Cato and McCauley 2002; National Research Council 2003). In areas of the Pacific Ocean where commercial shipping is more prevalent, measured ambient sound levels have ranged between 80 and 90 dB (Andrew et al. 2002; McDonald 2006). A variety of natural processes increases these levels: precipitation on the ocean surface contributes sound levels up to 35 dB across a broad range of frequencies (Nystuen and Farmer 1987); an increase in wind speed from 5 to 10 knots causes a 5-dB increase in ambient ocean noise across most frequencies. The highest noise levels generally occur in nearshore areas where the sound of surf can increase underwater noise levels by more than 20 dB a few hundred yards/meters outside the surf zone across a frequency band from 10 to 10,000 Hz (Wilson et al. 1985; National Research Council 2003).

[77] Relative sound intensities (i.e., decibel values) in water are not directly comparable to relative sound intensities in air. This is primarily because the reference intensities used to compute sound intensity are different in water and air. A standard reference intensity must always be used when comparing relative intensities to one another. For underwater sound, the intensity of a sound wave with a pressure of 1 microPascal at 3.3 feet (1 m) from the source point is used as the reference intensity. In air, however, the reference intensity is 20 microPascals at 3.3 feet (1 m).

Among noise sources associated with human activity, surface shipping is widely considered the most widespread source of low-frequency (5 to 1,000 Hz) noise in the oceans (Wenz 1962; National Research Council 2003; Hildebrand 2009). At frequencies below approximately 200 Hz, commercial shipping is the primary source of ocean ambient noise. While natural forces (e.g., wind, rain, waves) are the primary factor determining ambient noise levels in higher frequency ranges, there is virtually no correlation between local sea state and ambient noise at lower frequencies (Hildebrand 2009). Noise levels in the marine environment have increased since the mid-twentieth century, likely in part because of increases in shipping traffic (National Research Council 2003). Andrew et al. (2002) collected ocean ambient sound data from 1994 to 2001 using a receiver on the continental slope off Point Sur, California. These data were compared to measurements made from 1963 to 1965 by an identical receiver. The data demonstrated an increase in ambient noise over the 33-year period of approximately 10 dB in the frequency range of 20 to 80 Hz, primarily because of commercial shipping; there were also increases as large as 9 dB in the frequency ranges 100 Hz up to 400 Hz, for which the cause was less obvious (Andrew et al. 2002). McDonald (2006) compared data sets from 1964 to 1966 and 2003 to 2004 for continuous measurements west of San Nicolas Island, California, and found an increase in ambient noise levels of 10 to 12 dB at 30 to 50 Hz.

Puget Sound experiences a concentration of commercial shipping in and out of United States ports, with the ports of Seattle and Tacoma collectively representing 9 percent of 20-foot-equivalent (6-meter-equivalent) container traffic in 2010 (United States Army Corps of Engineers 2011). The OCNMS has designated a large portion of the action area as an area to be avoided (OCNMS 2022). Under this voluntary ship traffic management program, vessels are advised to stay clear of this area if they carry cargoes of oil or hazardous materials or if they exceed 400 gross tons (Subsection 3.1.1.1.3, Current Issues, Area to be Avoided, for more information). Veirs and Veirs (2006) found that the broadband sound field (i.e., 100 to 15,000 Hz) in Puget Sound near Haro Strait was dominated by noise from large vessels. With high source levels and long pulse lengths, military sonar signals (e.g., from low-frequency active sonar systems) are also likely a major source of low-frequency ocean noise over wide areas (Hildebrand 2009).

Owing to the physics of underwater sound propagation, small vessels do not contribute substantially to ocean ambient noise on a global scale, but they may be important local sound sources in coastal areas (Hildebrand 2009). In Haro Strait, Veirs and Veirs (2006) found that small vessels raised overall sound levels about as much as commercial ships (15 to 20 dB), but for shorter periods and at higher frequencies (10,000 to 20,000 Hz). At the end of 2022, 218,916 motor

boats were registered[78] in Washington State (Washington Department of Licensing 2023), with the majority likely operating near heavily populated areas surrounding Puget Sound. Scientific vessels, which can operate in a given area for several days at a time, generate noise at levels ranging from 160 to 190 dB at the source (National Research Council 2003). Received sound levels for whale-watching boats measured at approximately 299 feet (91 m) ranged up to 127 dB across a broad band of frequencies (315 to 2,500 Hz) (Au and Green 2000). Erbe (2002) documented increased sound levels for high-speed operation. Small powerboats have peak sound intensities of 145 to 150 dB in the 350 to 1,200 Hz band (Barlett and Wilson 2002). Fishing vessels also have moderate sound levels. Vessel traffic associated with commercial and recreational fishing in the action area is heaviest and, therefore, probably loudest, from May to August (Subsection 3.13.3.2, Marine Vessel Traffic). In the Haro Strait study area, the prevalence of small vessels contributed to average sound levels during summer days that were 3 dB higher than during summer nights, winter days, or winter nights (Veirs and Veirs 2006).

3.12 Aesthetics

3.12.1 Introduction

This section discusses aesthetics as visual resources associated with the action area, a place where the Pacific Ocean, beaches, rocky tidepools and headlands, and adjacent forested wilderness meet. In the designation documentation for the OCNMS, Congress described the area as "one of the more dramatic natural wonders of the coastal United States, paralleling the majestic splendor of such terrestrial counterparts as Yosemite National Park and the Grand Tetons," (59 FR 24586, May 11, 1994). Key visual resources in the action area include natural landscapes and seascapes, wildlife, and tangible cultural resources and historic artifacts.

Peoples' opportunities to view past and proposed Makah whale-hunting activities in the action area are described by detailing access points where hunting and landing of a whale might be seen. Annual numbers of visitors and primary seasons of viewing are also described. Because whale hunts would take place offshore, and because the Makah practice exercises in 1998 and hunts in 1999 and 2000 were highly covered and televised events, most opportunities for viewing the hunt and hunt-related activities would occur through the media, including newspapers and television. For this reason, this section also describes media coverage of the previous hunts, along with public response to that coverage.

[78] In Washington, all boats 16 feet (4.9 m) or more in length or with 10 or more horsepower are required to be registered; registration is not required for boats under those thresholds not used on navigable waters.

3.12.2 Regulatory Overview

As noted in Subsection 3.1, Geographically Based Management in the Action Area, several federal and tribal managed areas occur and overlap within the action area. These include the OCNMS, the Washington Islands National Wildlife Refuges, the coastal strip of the Olympic National Park, and the Makah and Ozette Indian Reservations (Figure 3-1). Because of their proximity to the action area, these management areas provide possible vantage points to whaling activities under each of the alternatives. The laws and regulations governing the management of these areas include recognition of the importance of aesthetic resources. In some cases, specific policy or management documents expand upon the aesthetic qualities that lend importance or value to the managed areas.

The National Marine Sanctuary Act, and NOAA's implementing regulations under which the OCNMS is designated and managed, include aesthetic values as important to the sanctuary concept. Sanctuary resources are defined as "any living or nonliving resource that contributes to the conservation, recreational, ecological, historical, educational, cultural, archeological, scientific, or aesthetic value of the Sanctuary," (16 USC 1432(8), 50 CFR 922.3). Subsection 3.1.1.1, Olympic Coast National Marine Sanctuary, describes the multiple-use nature of the Sanctuary, NOAA's regulations establishing prohibitions on certain uses of the Sanctuary, and the biological and historic characteristics of the Sanctuary that give it particular value as identified by the OCNMS designation document. Aesthetic resources of the Sanctuary that give it particular value include its remoteness, its undeveloped character, and its marine life, as well as tangible, historical resources including Indian village sites, ancient canoe runs, petroglyphs, and Indian artifacts (59 FR 24586, 24604, May 11, 1994; NOAA 1993).

The National Park Service Organic Act, governing the management of all national parks including the Olympic National Park, states that the fundamental purpose of national parks is "to conserve the scenery and the natural and historic objects and the wildlife therein and to provide for the enjoyment of the same in such a manner and by such means as will leave them unimpaired for the enjoyment of future generations" (16 USC 1). Both the National Park Service and Ecology manage the aesthetics of the shoreline under federally-granted Coastal Zone Management Act authority. The Coastal Zone Management Act identifies beaches as aesthetic resources of the nation (16 USC 1451(b)). Washington State's Shoreline Management Act establishes a program to coordinate the protection and development of the state's shoreline, preserving to the greatest extent possible the public's opportunity to enjoy the physical and aesthetic qualities of state

natural shorelines (RCW 90.58.020). The Makah Tribe also has a coastal zone management plan for reservation shorelines.

Approximately 70 percent of Olympic National Park's coastal strip, including 36,000 acres mostly north of the Hoh River, is designated as wilderness (National Park Service 2008). Under the Wilderness Act of 1964 (PL 88-577), wilderness areas are managed for the "preservation of their wilderness character" for current and future generations of Americans (16 USC 1131). Both natural and cultural resources are contributing elements to the Olympic National Park Wilderness (National Park Service 2008). The principles applied to federal wilderness areas also apply to management of the Washington National Wildlife Refuges, which are all designated as wilderness areas, except for Destruction Island in the Quillayute Needles National Wildlife Refuge. Other protective regulations are described in Subsection 3.1.1.2, Washington Islands National Wildlife Refuges. Reservation lands along the shoreline around Cape Flattery are also designated wilderness.

Living marine resources within the action area, including, but not limited to, whales and other marine mammals, are also protected by federal and state statute and regulation as aesthetic resources. The Whaling Convention Act, for instance, includes the finding that whales are a unique marine resource of great aesthetic and scientific interest to mankind and notes that the protection and conservation of whales are of particular interest to citizens of the United States (16 USC 916 note, PL 96-60, August 15, 1979). The MMPA also includes the Congressional finding that "marine mammals have proven themselves to be resources of great international significance, aesthetic and recreational as well as economic" (16 USC 1361(6)).

3.12.3 Existing Conditions

The following sections describe the key visual resources in the action area, vantage points into the Makah U&A, and estimates of the number of visitors to these areas every year. Following the discussion of potential direct viewing opportunities is a summary of media coverage of previous hunts.

3.12.3.1 Visual Resources in the Action Area

The sea stacks, pillars, and islands that make up the Washington Islands National Wildlife Refuges within the OCNMS are a visual resource of statewide significance, representing the remote and rugged nature of the Olympic Peninsula's coastline (USFWS 2007). The islands rise out of the ocean in a variety of shapes and forms and are varying distances from the shoreline; formations in the foreground often appear as flat-topped cliffs rising out of the water, while formations in the background appear as clusters of often fog-shrouded stacks (USFWS 2007).

Many of the islands have vegetation, including small trees and shrubs, particularly the larger islands (such as Ozette Island). Other smaller islands have extensive steep grassy slopes or vegetated ledges (USFWS 2007). The islands also provide views of hauled-out sea lions and seals, migrating and feeding whales, and sea otters, among other species (Subsection 3.5.3.1.2, Common Species off Washington Coast). Many species of seabirds are visible in the marine waters, off the coastal headlands and islands, and along the shore, including raptors, gulls, petrels, cormorants, auks, murrelets, guillemots, common murres, auklets, and puffins, among others (Subsection 3.5.3.2.1, ESA-listed Species, and Subsection 3.5.3.2.2, Non-listed Marine Birds and Their Associated Habitats, for more information on marine birds that occur in the action area).

In the Olympic National Park, more than 650 archaeological sites document 10,000 years of human occupation, while historic sites reveal clues about the 200-year history of exploration, homesteading, and community development in the Pacific Northwest (National Park Service 2008). Maritime archaeological sites include stratified shell midden deposits and petroglyph sites and represent one of the Olympic National Park's most important and threatened classes of archaeological resources. Threats include coastal erosion and visitor use. Past mitigation at these areas has included excavation, bank stabilization, and revegetation (National Park Service 2008). Public education and interpretation, coupled with increased monitoring and ranger patrols, aims to curb the impacts of visitation and tidal debris on the coastal petroglyph sites, particularly at Wedding Rocks, a site on the beach near Cape Alava (National Park Service 2008).

3.12.3.2 Vantage Points and Viewing Opportunities

Visitors can view the portion of the Makah U&A in the Strait of Juan de Fuca by vehicle at several locations along Highway 112, including the towns of Sekiu, Clallam Bay, and Neah Bay. In contrast, vehicle-based viewing opportunities for the Pacific coastal portion of the U&A are limited to a few sites on the Makah Reservation, mostly in the Tsoo-Yess and Hobuck Beach area of Makah Bay. No roadways offer views of the southern portion of the Makah U&A. The La Push/Rialto Beach area is approximately 8 miles (13 km) south of the Makah U&A. The only scenic driving opportunity along the coast of the Olympic Peninsula is an 8-mile (13-km) stretch of United States Highway 101 in the Kalaloch area, which is more than 30 miles (48 km) south of the Makah U&A (National Park Service 2008).

Most of the land-based viewing access in the action area is from hiking trails and beaches (where camping opportunities exist), including the Cape Flattery Trail and Hobuck and Tsoo-Yess beaches on the Makah Reservation. The Olympic National Park also provides hiking and backpacking access to 50 miles (81 km) of beaches with views of the islands. The Ozette/Shi Shi

portion of the Olympic National Park, including the Point of Arches, is the most visible and photographed place in the Olympic National Park coastal strip. Many visitors also access the beach for 2.9 miles (4.7 km) between the Cape Alava and Sand Point trail heads (National Park Service 2008).

Around 3 million people visit the Olympic National Park on average every year, drawn by the beautiful scenery and the pristine wilderness, as well as opportunities to view wildlife and challenge themselves in a natural environment (National Park Service 2022). More than half of the visits occur during the months of July through September and an additional 25 percent of the visits occur during the months of March through June (National Park Service 2022). Part of the Makah U&A is visible to OCNMS visitors and overnight campers and to hikers on the Cape Flattery Trail.

In 2019, a sensor on the Cape Flattery Trail recorded 50,000 trips of hikers. After reopening the Reservation in March of 2022, the sensor recorded 73,500 trips over the next year (J. Cooke, Makah Tribe, pers. comm., April 21, 2023). Use of the Cape Flattery Trail is greatest from June through September.

Another driver of visitation to Neah Bay is the celebration of Makah Days (Subsection 3.10.3.5, Contemporary Makah Society). This celebration of Makah identity features a parade, street fair, canoe races, children's races, traditional dancing, a salmon bake, and fireworks (Tizon 1998a).

Previous authorized hunts in 1999 and 2000 occurred within the Makah U&A and OCNMS, along and adjacent to the coastal area of the Olympic National Park. Whale hunting activities were visible from Ozette Island, Cape Alava, and Sand Point to Father and Son Rock, the Point of the Arches, and Spike Rock near the Ozette Reservation and Shi Shi Beach (Gosho 1999) (Subsection 1.4.2, Summary of Recent Makah Whaling—1998 through 2007, for more information about the locations of the 1999 hunt). People on trails and beach vantage points of the Olympic National Park may have viewed the hunts, including the May 17, 1999 killing of a gray whale. The possibility that some viewers were caught unaware is extremely unlikely because May is not a peak visitor month, the hunts were well-advertised in the media, and the weather conditions were poor (Gosho 1999) at least some of the time. People on the shores of Neah Bay on the Makah Reservation could view the whale being towed to shore and flensed. These activities were also visible to protesters, enforcement personnel, and tribal members in vessels surrounding the hunts. Most of those viewing the whaling activities on the shore within the Makah Reservation were tribal members who supported the hunt and had favorable reactions. As reported by the *Seattle Times*, Makah tribal members in Neah Bay considered the visual effects of

the hunt as ". . . cause for celebration, a triumphant embrace of tradition and heritage, a culture's central symbol giving itself up for the kill" (Sorensen 1999).

During the May 1999 whale hunts, news reports indicate that vehicular access to State Route 112 paralleling the Strait of Juan de Fuca was blocked by protesters and tribal police for about 2.5 hours (Mapes and Solomon 1999a). Such blockages may have interrupted access to visual resources on the Olympic Peninsula. Traffic volumes on the land were otherwise normal (Subsection 3.13.3.1.2, Vehicle Traffic Patterns During the 1999 Hunt).

3.12.3.3 Media Coverage of Previous Authorized Hunts

The practice exercises, whale hunts, and associated protest activities that occurred in 1998, 1999, and 2000 were the focus of intensive media coverage in the region, including Seattle. In late summer and autumn of 1998, approximately 50 representatives of media organizations from all over the world arrived at Neah Bay to watch the Makah Tribe hunt whales (Mapes 1998a). Media coverage became an issue during the Makah Days celebration in August 1998, when its representatives crowded in front of tribal dancers, disrupting the formal welcoming ceremony (Clarridge 1998). From June 1998 to June 1999, whale-hunt-related news stories abounded in local newspapers. The *Seattle Post-Intelligencer* published 77 news items and three editorials on the topic during that period. The *Seattle Times* published 76 news items, 11 columnists' commentaries, and eight editorials during the same timeframe. Such intense attention was largely limited to the region, however. During the same period, the *New York Times* published 16 news items with the words 'Makah' and 'whale,' the *Los Angeles Times* published 13 related news items, and the *Washington Post* published three related news items.

Media coverage resumed when the Makah resumed hunting activities in April of 2000 but with less intensity than for prior hunts. Between April 1 and December 31, 2000, the *Seattle Post-Intelligencer* published 13 news items and one editorial about the hunt, protests and protesters, and associated legal actions. The *Seattle Times* published 15 news items and one editorial on hunt-related topics during the same period. As before, the hunt received considerably less attention outside of the Pacific Northwest. The *New York Times* published two hunt-related news items from April through December of 2000, the *Los Angeles Times* published four, and the *Washington Post* published a single hunt-related news item.

News of the Makah Tribe's successful hunt on May 17, 1999 received attention in local print and broadcast media. Locally, the Seattle *Post-Intelligencer* printed five photographs showing the whale in the water or on the beach; the *Seattle Times* printed four photographs, and the *Peninsula Daily News* printed seven photographs. At least two local television stations, KING-TV and

KOMO-TV, sent helicopters to collect video footage of the hunt and subsequent activities. KING-, KOMO-, and KIRO-TV all extended their morning news shows to cover the story of the successful hunt, which occurred shortly before 7 a.m. (Levesque 1999). KCPQ-TV, which did not have a morning news show at that time, interrupted regular programming with occasional updates. Northwest Cable News network, a sister station of KING-TV, ran near-constant footage and commentary on May 17, and 10 hours of live broadcast of the previous day's unsuccessful hunt (Levesque 1999; McFadden 1999).

Nationwide, the story of the successful hunt received considerably less attention. Most newspapers simply published the Associated Press wire story. There was no international Web site coverage by well-known news sources such as the *London Times*, *Le Monde*, *Asahi Shimbun*, and the *Japan Times* (Barber 1999). The story was broadcast on nationwide television, however, accompanied by commentary by Peter Jennings, ABC Network, and Tom Brokaw, NBC Network. Some observers characterized the images of the dying and dead whale as brutal and suggested that footage of the whale killing would pose a public relations problem for the Makah Tribe (Sorensen 1999).

Local newspaper reader response to the hunt was substantial. The *Seattle Times* received nearly 500 letters on the topic during the latter half of May 1999, nearly one-third of the total number of letters received for that month (Anderson 1999). On the day following the successful hunt, the *Seattle Post-Intelligencer* received more than 50 e-mail messages and more than 100 telephone calls voicing opinions about the hunt (Barber 1999). The *Peninsula Daily News* also reported an unusually large volume of letters and devoted a special letters page to the topic on the Friday following the hunt (Brewer 1999). KING-TV reported that the issue generated three or four times the normal volume of phone calls and e-mail messages related to a news story (Levesque 1999).

The news director at KIRO-TV chose not to broadcast images of the actual killing of the whale because some viewers had said they did not want to see explicit footage (Levesque 1999). Nearly all public response focused on the issue of killing the whale. Only a few comments offered reactions to images of the event, for example, "I can't believe you think most of the population in Western Washington is remotely interested in viewing the graphic video" (Levesque 1999).

The *Seattle Post-Intelligencer* published excerpts of some telephone and e-mail messages received in response to their coverage of the whale hunt (*Seattle Post-Intelligencer* 1999). While most responses expressed support for or protest against the hunt, some included reactions to published images. One commenter expressed disgust at the image of Makah whalers jumping on the carcass of the whale. Another stated that the hunt of a whale should not be broadcast on

television. One letter to the editor read "tonight I refuse to watch any news program for fear I will see another replay of the Makah hunt" (*Seattle Post-Intelligencer* 1999).

Of more than 30 letters published in the *Peninsula Daily News* on Friday, May 21, two contained reactions to images of the hunt. One writer described the television footage as "the most disgusting sight" she had ever seen. Another expressed the opinion that the graphic coverage should prompt viewers to express their objections to their congressional representatives (*Peninsula Daily News* 1999).

A Google search indicated about 710 instances of media coverage in the 20 days following the September 8, 2007 unauthorized hunt, the majority in the first few days afterward. Media outlets all over the country reported the event, often using Associated Press information. Follow-up coverage included reports on the Tribe's apology and trip to Washington, D.C. The *Los Angeles Times*, *Washington Post*, and *New York Times* each ran one or two stories. Most of the coverage emanated from western Washington media. Seattle TV stations provided live reports from Neah Bay for the first few days. The *Seattle Times* had the most extensive coverage, with Lynda Mapes writing several in-depth articles. The *Times* also asked for reader feedback; 93 comments with a wide range of views were posted in response. The *Seattle Post-Intelligencer* and Port Angeles *Peninsula Daily News* ran multiple stories about the kill and activities following it. Other regional media had less extensive coverage. As news interest waned, there were several editorials and opinion pieces published, also with a wide range of views expressed.

Some anti-whaling websites that were active during the earlier authorized hunts are no longer in existence or are not current. The Humane Society of the United States, Whale Police, Sea Shepherd, and Animal Welfare Institute posted press releases on their websites condemning the September 8, 2007 whale kill. The few blogs covering this issue linked to or extracted from various media reports on the Internet, with limited commentary. Views seemed to be about equal between condemnations of the kill and of whale-hunting in general, and support for tribal rights and culture.

The intensity of media coverage moderated over the following years as attention turned to the Tribe's pursuit of a waiver under the Marine Mammal Protection Act. In August 2019, news outlets reported on the Tribe's ceremonial and subsistence use of a humpback whale killed by a ship strike in the Tribe's Usual and Accustomed Fishing Area. The coverage highlighted the role of whales in tribal culture and the tribal celebration surrounding the traditional uses of the whale carcass. When NMFS convened a hearing in Seattle on the proposed waiver and regulations in November 2019, several local media outlets covered the start of the hearing, describing the

Tribe's longstanding pursuit of the waiver to authorize tribal hunts. Much of the coverage explained that the Tribe's treaty with the U.S. Government provides for whaling and gave voice to tribal leaders who described the cultural and spiritual importance of whaling. News reports appeared across the region and in national media including the *Los Angeles Times* (Rust 2019) and *New York Times* (Eligon 2019), explaining tribal culture and practices, which reflected the proposed waiver and the Tribe's position more positively than earlier reports focusing on past hunts.

3.13 Transportation

3.13.1 Introduction

The following section documents several transportation-related issues pertaining to the Makah whale hunt. Transportation resources near Neah Bay include federal and state highways, marine vessels, and airports. Key parameters for analysis include the patterns of highway, marine vessel, and air traffic near Neah Bay.

3.13.2 Regulatory Overview

At the federal level, the Federal Highway Administration within the Department of Transportation is responsible for the management of the national highway system, which includes United States Highway 101 near Neah Bay (23 USC 101). The national highway system consists of interconnected urban and rural principal arterials and highways that serve major population centers, international border crossings, ports, airports, public transportation facilities, other intermodal transportation facilities, and major travel destinations; meet national defense requirements; and serve interstate and interregional travel (23 CFR 470A).

The Federal Highway Administration is responsible for stewardship and oversight of the federal-aid highway funds allocated to Washington State. The Washington State Department of Transportation is the state agency responsible for delivering these federal-aid funds. Under the Statewide Multi-Modal Transportation Plan (RCW 47.06), the Washington Department of Transportation is responsible for developing a statewide multi-modal transportation plan in conformance with federal requirements. The highway system includes both state and federal highways. Neah Bay is reached via United States Highway 101 to State Route 113 north and then to State Route 112 northwest along the western coast of the Makah Indian Reservation and terminating at the center of Neah Bay.

In the marine environment, the Washington State Department of Transportation has the responsibility to oversee the national transportation system, which includes the marine

transportation system (49 USC 101). The Coast Guard is responsible for enforcement and administration of laws governing vessels, cargo, and passengers. The Coast Guard has established a permanent RNA along the northwestern Washington coast and in a portion of the entrance to the Strait of Juan de Fuca (33 CFR 165.1301). Within the RNA, a moving exclusionary zone restricts the movements of vessels near a Makah vessel that is actively engaged in a whale hunt. Coast Guard restrictions for marine vessels engaged in whale hunting activities are described in greater detail in Subsection 3.1.1.3, Coast Guard Regulated Navigation Area, and Subsection 3.15.2.1, Vessel Safety Regulations and Authorities.

The International Maritime Organization has designated a formal area to be avoided for the OCNMS. Vessels advised to stay clear of this area include all ships and barges carrying cargoes of oil or hazardous materials and all ships 400 gross tons and larger (Subsection 3.1.1.1.3, Current Issues, Area to be Avoided, and Subsection 3.2.3.3, Spill Prevention).

Air traffic safety is the responsibility of the Federal Aviation Administration (FAA). In 2012, NOAA's Office of National Marine Sanctuaries announced collaborative overflight regulations with the FAA that prohibit flying motorized aircraft less than 2,000 feet (610 m) above certain portions of the Sanctuary (77 FR 3919, January 26, 2012; Subsection 3.1.1.1.2, Designation and Regulatory Overview [OCNMS]). These include all areas within 1 nautical mile (1.9 km) of the coastal boundary of the sanctuary, as well as areas within 1 nautical mile of any of the islands that constitute the Flattery Rocks, Quillayute Needles, or Copalis National Wildlife Refuges (15 CFR 922.152). These prohibitions do not apply to activities in response to emergencies threatening life, property, or the environment, or those for valid law enforcement purposes.

3.13.3 Existing Conditions

3.13.3.1 Highway Vehicle Traffic

Primary access to the isolated community of Neah Bay is via State Route 112, a narrow, winding highway that parallels the Strait of Juan de Fuca through rolling, forested terrain. An alternative route is along the closest primary highway, United States Highway 101, to Sappho and then north on a separate highway (State Route 113) that ends at State Route 112. In recognition of its outstanding scenic, recreational, and cultural qualities, State Route 112 has been designated as a national scenic byway by the U.S. Secretary of Transportation.

3.13.3.1.1 Typical Vehicle Traffic Volume Patterns

The Washington State Department of Transportation conducts traffic counts occasionally on State Route 112 at the boundary of the Makah Reservation. The most recent traffic counts were

conducted in 2022. The Traffic Count Database System (TCDS)[79] reported an annual average two-way traffic volume at the Makah Indian Reservation boundary of 865 vehicles in 2022. The Department of Transportation reported a high annual average daily traffic volume of 956 in 2015 for this area and a ten-year low of 795 in 2020 (Washington Department of Transportation TCDS, accessed March 10, 2023).

The closest permanent, full-time automated data collection station is located on United States Highway 101, near the State Route 113 turnoff to Neah Bay. Data from this station provide an indication of highway traffic patterns and trends near Neah Bay. Daily traffic counts at that station vary with the day of the week, with Fridays typically 10 percent higher than average and Sundays 7 percent below average (Washington Department of Transportation, TCDS, accessed April 10, 2023). In 2022, traffic counts showed a strong pattern of seasonal variability, with the highest daily averages occurring during the summer months (July and August) and the lowest occurring in winter (November, December, and January) (Figure 3-12). This pattern is characteristic of locations where recreational travel represents a substantial component of total annual traffic volumes (Washington Department of Transportation, TCDS, accessed April 10, 2023). Over the past 10 years, average daily traffic counts at this station have varied between approximately 2,500 and 3,300 vehicles per day, with no strong increasing or decreasing trend (Figure 3-13).

[79] See https://wsdot.public.ms2soft.com/tcds/tsearch.asp?loc=Wsdot&mod=TCDS for publicly-available traffic count data through the Washington State Department of Transportation.

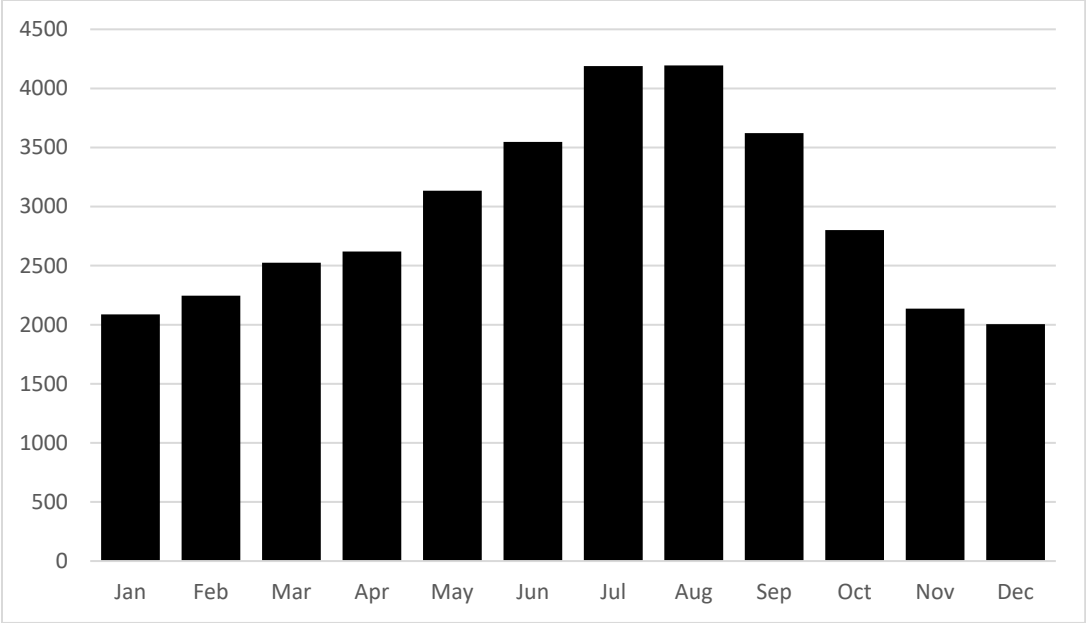

Figure 3-12. Average weekday traffic counts on Highway 101 near State Route 113, Station R073, by month (Washington Department of Transportation, TCDS, accessed April 10, 2023).

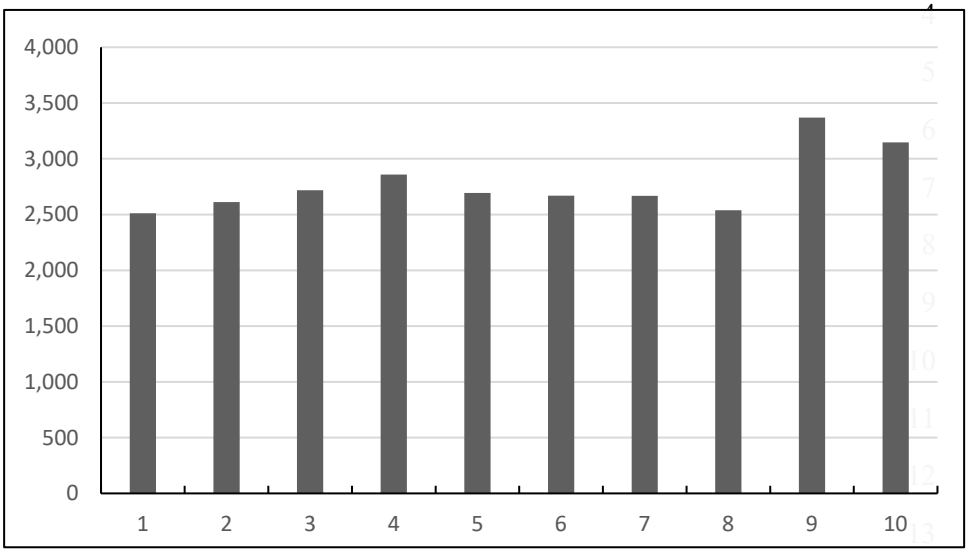

Figure 3-13. Annual average daily traffic counts on Highway 101 near State Route 113, 2013 to 2022 (Washington Department of Transportation, TCDS, accessed March 10, 2023).

Visitation data for the Cape Flattery Trail and the Makah Museum may serve as indirect indicators of the amount of vehicle traffic on the Makah Reservation. In 2004, a natural resource interpreter at the Cape Flattery Trail recorded visitor numbers in July, August, and September. The interpreter was present from roughly noon until 6:00 p.m.; visitors who arrived before and departed after the counting period were not counted, so these data represent an underestimate of actual visitation. Based on these data, the trail received an average of 169 visitors per day in July,

189 per day in August, and 93 per day in September (Bowechop 2005b). Additional data obtained during 2005 to 2011 (excluding 2007) indicate that over 16,500 people per year visit the Cape Flattery Trail (J. Bowechop, Makah Cultural and Research Center, pers. comm., June 26, 2012). More than 60 percent of the annual visitors to the Makah Cultural and Research Center/Makah Museum arrive during June, July, and August (North Olympic Peninsula Visitor and Convention Bureau 2005). Annual numbers of non-Makah visitors to the Makah Cultural and Research Center ranged from 6,405 to 10,678 people during 2007 through 2011 (J. Bowechop, Makah Cultural and Research Center, pers. comm., June 26, 2012). Additional information about tourist visitation to the Makah Reservation can be found in Subsection 3.6.3.2.4, Contribution of Tourism to the Local Economy.

3.13.3.1.2 Vehicle Traffic Patterns During the 1999 Hunt

News accounts of the 1998 and 1999 whale hunts described one occasion on which highway traffic was affected by activities associated with the hunt. Two days before the successful hunt on May 17, 1999, highway traffic was stopped for approximately 2.5 hours after the road was blocked by protesters and tribal police (Mapes and Solomon 1999a). No other highway blockages are described in news accounts or law enforcement records from the previous hunt, although Coast Guard records mention the occurrence of weekly protests on State Route 112 at the Makah reservation boundary (U.S. Coast Guard 1999c). Refer to Subsection 3.14.3.2, Police, for a discussion of traffic stops near Neah Bay.

Automated traffic count data for Highway 101 for the month of May 1999 do not indicate any anomalous spikes in traffic volume during the days surrounding the events of May 17, 1999. Traffic volume data for that date, along with May 22, the date of the Tribe's celebration of the successful hunt, are denoted in bold font in Table 3-41. Two trends are evident in the data. First is a steady increase in traffic volumes throughout the month, peaking on Memorial Day weekend (May 31). Second is the weekly pattern described above, wherein Friday volumes typically exceed those on Sundays. This pattern is evident in the data from the months of May 1998, 1999, and 2000; Friday volumes typically exceed those of the subsequent Sunday by at least 15 percent (Washington Department of Transportation 2005).

Table 3-41. Daily traffic counts on Highway 101 near State Route 113, May 1999.

Week Number	Sunday	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday
1							2,340
2	2,002	2,376	2,393	2,420	2,382	2,618	2,422

3	2,143	2,432	2,458	2,486	2,530	2,764	2,558
4	2,318	**2,465**	2,502	2,635	2,680	3,159	**3,221**
5	3,161	2,994	2,647	2,782	2,954	3,431	3,446
6	3,569	3,150					

Source: Washington Department of Transportation 2005.
Note: Bold font indicates the dates of the successful hunt (May 17, 1999) and the subsequent celebration (May 22, 1999).

This pattern does not hold true on Memorial Day weekends, when Sunday volumes can approach or even exceed those of the preceding Friday. The only other exception to this pattern occurs during the weekend of May 21 to 23, 1999, when Sunday traffic exceeded traffic on the preceding Friday, although barely. This anomaly may be attributable to many factors, such as weather, and may also reflect trips by participants attending the May 22 feast and celebration.

3.13.3.2 Marine Vessel Traffic

Marine vessels that travel to Neah Bay may find moorage at the Makah Marina, where more than 200 fishing vessels (commercial and recreational) and pleasure craft can anchor. In addition, several thousand large vessels pass by Neah Bay each year on their way through the Strait of Juan de Fuca to ports in Canada and the United States.

3.13.3.2.1 Fishing Vessel Traffic

The amount of marine vessel traffic associated with commercial fishing activity can be estimated by counting commercial fish tickets for vessels that land at the Neah Bay Marina. Both tribal and non-tribal fishers are required by law to complete a fish ticket when they land their catch. Rarely, catch from a single trip might be listed on two tickets. In other cases, a vessel may engage in day-fishing trips for several days and then make a single landing. Statistically, these two circumstances offset one another and do not occur frequently enough to affect the overall total counts.

Estimates of vessel traffic associated with recreational fishing are based on vessel counts conducted by the Washington Ocean Sampling Program. Between mid-April (for 2005-2011) or mid-March (for 2012 onwards) and October, sport fishing vessels are counted either leaving the port (between 4:30 a.m. and the end of the day) or entering the port (between 8:00 a.m. and dusk).

Total vessel landings at Neah Bay decreased by 34 percent between 2005 and 2008, then rebounded almost to 2005 levels by 2011 (Table 3-42). In the last decade (2012 to 2022), recreational and commercial landings are lower, on average, as compared to previous years (Table 3-42). Most vessel traffic at Neah Bay is associated with recreational trips, which account for approximately 86 percent of all boat trips in the last 10 years. In most years, the peak of

recreational fishing activity occurs in the months of July and August (salmon fishing season), with a secondary peak during the halibut season in May (Figure 3-14). However, in the most recent decade, recreational fishing effort in May has eclipsed that of August (Figure 3-14). Recreational fishing trips decrease dramatically in September, and commercial trips exceed recreational trips by October (Washington Department of Fish and Wildlife 2012; 2023a; 2023b). On average (excluding 2020 and 2021 due to COVID restriction closures), approximately 80 percent of all boat trips (commercial and recreational) occur during the months of May, June, July, and August. The 5-month period from November to March accounts for approximately 6 percent of all trips. Six percent of all trips occur in April, 6 percent in September, and 2 percent in October.

Table 3-42. Recreational and commercial fishing vessel landings at Neah Bay, 2005 to 2022 (data from WDFW 2023c, 2023d).

	2005	2006	2007	2008	2009	2010	2011[2]
Recreational Landings	12,968	11,053	11,327	8,154	11,113	9,957	12,802
Commercial Landings	3,718	3,499	3,711	2,864	3,215	3,306	3,532[3]
TOTAL	**16,686**	**14,552**	**15,038**	**11,018**	**14,328**	**13,263**	**16,334**

	2012	2013	2014	2015	2016	2017	2018	2019	2020*	2021*	2022
Recreational Landings	9,766	10,789	11,866	10,647	9,413	9,842	10,009	10,787	8	0	8,540
Commercial Landings	4,110	2,684	3,135	3,477	2,814	3,002	1,815	1,712	925	950	1,370
TOTAL	**13,876**	**13,473**	**15,001**	**14,124**	**12,227**	**12,844**	**11,824**	**12,499**	**933**	**950**	**9,910**

*2020 closed for public access in March and did not reopen until April of 2022 due to COVID restrictions

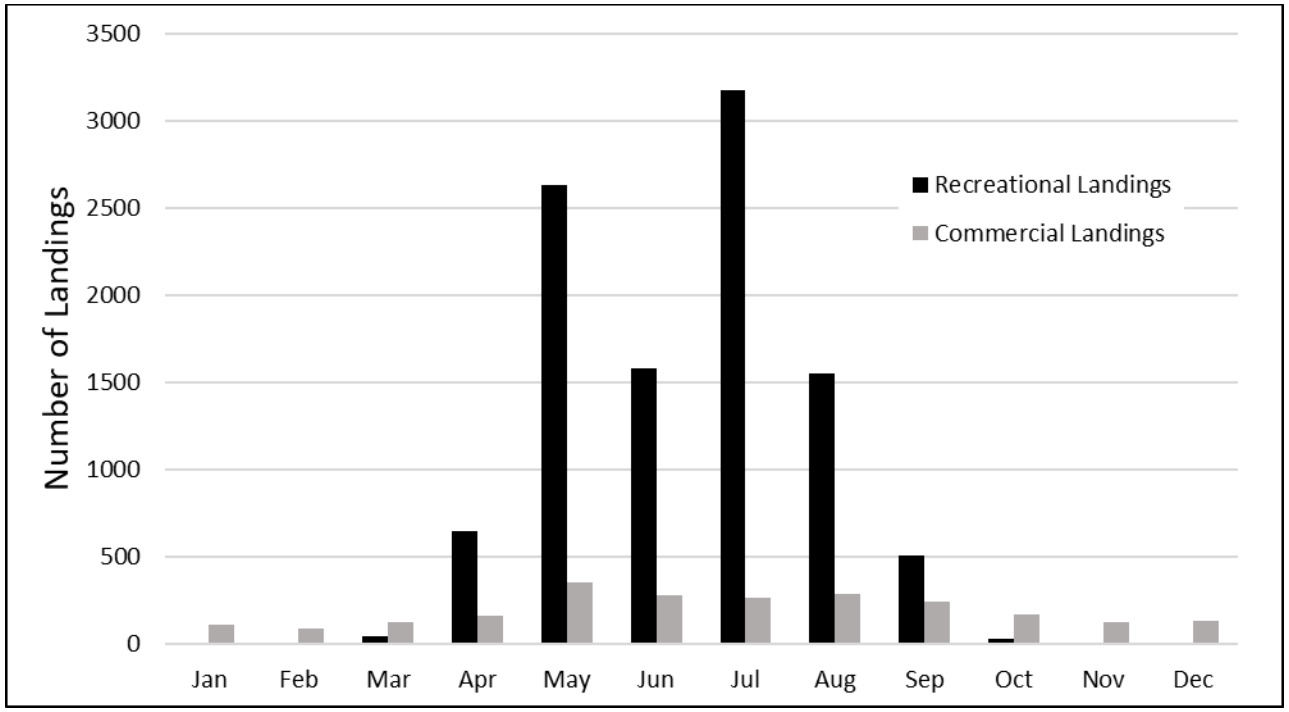

Figure 3-14. Average monthly levels of marine vessel traffic at Neah Bay, 2012 to 2022, excluding 2020 and 2021 for recreational landings due to COVID-19 restriction closures (data from WDFW 2023c, 2023d).

3.13.3.2.2 Offshore Vessel Transits

Ecology produces annual reports of the number of entering transits by various vessel types. An entering transit is defined as the passage of a vessel from sea or from Canadian waters into Washington State waters, regardless of destination (Ecology 2012b). The data collected by the department identify commercial fishing, cargo, and passenger vessels 300 gross tons (272 mt) and larger, as well as tank ships and tank barges transporting oil of any tonnage. Entering transits at the Strait of Juan de Fuca provide a measure of the amount of marine traffic near the Makah Tribe's U&A. From 2019 to 2021, Ecology reported roughly 4,400 to 4,800 entering transits annually via the Strait of Juan de Fuca (Table 3-43). This averages to approximately 12-13 large vessels per day, with cargo and passenger vessels making up more than 80 percent of entering transits. Personnel at the Canadian Coast Guard's Tofino Station have observed very little seasonal variability in traffic volume, except in the case of fishing vessels.

Table 3-43. Vessel transits using the Strait of Juan de Fuca, 2019 to 2021.

Vessel Type and Destination	2019		2020		2021
Cargo and Passenger Greater than 300 Gross Tons[1]					
Washington Ports	1,497		1,402		1,594
Canadian Ports	2,784		2,472		2,485
Tank Ships and Barges					
Washington Ports	355		336		331
Canadian Ports	177		196		178
TOTAL	**4,813**		**4,406**		**4,588**

Source: Ecology 2020, 2021b, 2022b.

[1] Includes fishing vessels and factory fishing vessels/processors.

The Tofino Station provided an estimate of approximately 40 to 50 vessel transits per day in the Strait of Juan de Fuca (entering and leaving), which equates to 20 to 25 entering transits. Based on a comparison of this estimate with the values reported by Ecology, approximately half of the daily transits are vessels less than 300 gross tons (272 mt) and not transporting oil.

3.13.3.2.3 Marine Traffic During the Previous Hunt

In the fall of 1998, as the Makah Tribe attempted to implement the first season of its hunt, several protest vessels began a 2-month occupation of Neah Bay to prevent the taking of a whale. From late September to late November, more than 15 protest vessels trailed any boat that left the Neah Bay marina (Dark 1999). Most of the protest vessels moored each night in Sekiu, a half-hour boat ride away (Mapes 1998a). The Sea Shepherd Conservation Society anchored the 180-foot (55-m) *Sea Shepherd III* and the 95-foot (29-m) cutter *Sirenian* outside Neah Bay and publicized plans to use a 27-foot (8-m) former Norwegian military submarine painted to resemble a full-grown killer whale

(Mapes 1998a; Tizon 1998b). The number of protest vessels was smaller when the hunt resumed the following spring; approximately a dozen boats returned to Sekiu (Mapes and Solomon 1999b). In 1999 and 2000, the Coast Guard intercepted several protest vessels for various hunt-related violations (Subsection 3.14.3.1, Coast Guard). There is no evidence that vessel transits using the Strait of Juan de Fuca were anomalously high or low during 1999 and 2000. However, Ecology does not report vessel traffic by month (only by year), so it is not possible to determine if there were short-term changes in marine traffic patterns during the active hunt periods in those years.

3.13.3.3 Air Traffic

Three airports serve Neah Bay and the western portion of Clallam County. Closest to Neah Bay is the Sekiu Airport, approximately 20 miles (32 km) east on Highway 112. The Federal Aviation Administration (2020) estimates approximately 850 operations occur annually at the airport. The airport has a visual approach slope indicator system, which is a set of lights that provide visual descent guidance information during the approach to a runway.

The Forks area, approximately 30 air miles (48.3 air km) from Neah Bay (50 miles [80.5 km] by highway), has two public access airports. The Forks Municipal Airport, located on the south edge of the City of Forks, has a 2,400-foot (732-m) paved runway and receives approximately 13,600 annual operations (Federal Aviation Administration 2019). The Coast Guard uses the airport as a refueling station for its helicopters. The airport is also used by emergency medical air transport helicopters that service the Forks Community Hospital (Newkirk and Casavant 2002). The Quillayute Airport is a former Naval Auxiliary Air Station located approximately 10 miles (16 km) west of Forks. For the 12 months ending on December 31, 2019, the airport received approximately 6,700 takeoffs and landings (Federal Aviation Administration 2019). Neither the Forks nor the Quillayute Airport has an approved instrument approach that would allow flights to proceed in inclement weather conditions (Newkirk and Casavant 2002).

Experience from the 1999 hunt indicates that media aircraft can operate at altitudes more than 2,000 feet (610 m) above water. On the day of the successful hunt, three television news helicopters were present throughout the day; according to Coast Guard accounts of the day, the aircraft observed all safety precautions (U.S. Coast Guard 1999a). The only problem with aircraft occurred on one day in 1998 when a seaplane operated by protest groups made several passes lower than 2,000 feet (610 m) over the area of the hunt. Operators of the aircraft were subsequently contacted by the Coast Guard, and the activity did not recur.

3.14 Public Services

3.14.1 Introduction

The following subsection documents several public service-related issues pertaining to the Makah whale hunt. Key parameters for analysis include staffing and occurrence rates of incident responses for local law enforcement agencies, including the Coast Guard and police. Also included is a discussion of public health facilities near Neah Bay.

3.14.2 Regulatory Overview

No specific regulations pertain directly to the establishment or maintenance of public services in the action area.

3.14.3 Existing Conditions

3.14.3.1 Coast Guard

The Coast Guard maintains Station Neah Bay, a small boat station within the Makah Indian Reservation. The station is staffed by 34 active-duty personnel; equipment includes two 47-foot (14-m) motor lifeboats, one 41-foot (13-m) utility boat, and one 25-foot (8-m) response boat (U.S. Coast Guard 2012). The station also features a helicopter landing pad with fueling facilities. The station's area of responsibility extends from the Strait of Juan de Fuca east to Pillar Point and south to Cape Alava. The station responds to approximately 100 search and rescue cases a year, primarily during the summer when sports fishers and tourists are present in greatest numbers (U.S. Coast Guard 2012). The station's crew is also responsible for maritime law enforcement in the area, conducting approximately 200 safety boardings per year.

During the previous Makah whale hunt practice exercise in 1998 and hunts in 1999 and 2000, Coast Guard personnel were responsible for ensuring the safety of persons and vessels near the hunt. To this end, the Coast Guard enforced an RNA and a 500-yard (457-m) moving exclusionary zone (MEZ) around tribal vessels actively engaged in the hunt. This MEZ was designed to keep protesters, reporters, and spectators out of the area where life and property would face the greatest risk of endangerment from an injured or pursued whale or a round from a .50-caliber rifle. Refer to Subsection 3.1.1.3, Coast Guard Regulated Navigation Area, and Subsection 3.15.2.1, Vessel Safety Regulations and Authorities, for more information about operation of the RNA and MEZ in prior hunts. The Coast Guard used helicopters, a cutter, and several utility boats and Zodiacs to enforce the exclusion zone (Mapes and Solomon 1999b). In October and November of 1998, two additional 41-foot (13-m) utility boats were made available,

if needed, but no extra personnel were placed on duty (Mapes 1998d). In May 1999, the Coast Guard cited the operators of four protest boats for grossly negligent operations and/or MMPA take violations, and three of the vessels were taken into federal custody (NMFS 1999; U.S. Coast Guard 1999c; U.S. Coast Guard 1999d). In April 2000, a Coast Guard utility boat responded to a protest vessel that was violating the exclusionary zone around a Makah canoe engaged in the whale hunt. Refer to Subsection 1.4.2, Summary of Recent Makah Whaling – 1998 through 2007, and Subsection 3.15.3.4, Behavior of People Associated with the Hunt, for more details about protest activities.

3.14.3.2 Police

The Makah Tribal Police have jurisdiction over crimes and infractions committed by Native Americans from any tribe on reservation lands. In addition, the tribal police have the authority to detain non-Indians for violations of law occurring on the reservation until they can be turned over to the appropriate authority (county, state, or federal). Refer to Subsection 3.1.2.1, Makah Tribal Departments and Agencies, for a description of the tribal police department and Subsection 3.1.2.2.1, Makah Public Safety Program, for a description of the Tribe's emergency management plan.

Non-tribal law enforcement activity in the area is conducted by the Clallam County Sheriff's Department. The patrol division of the Sheriff's Department is responsible for police patrols in all unincorporated areas of Clallam County, responding to calls for service made by citizens in need of police assistance and actively seeking out crime and traffic offenders. The closest deputy lives approximately 20 to 30 minutes from Neah Bay, which would be the minimum amount of time required to respond to an unanticipated law enforcement need. The Washington State Patrol oversees traffic safety compliance on roads and highways in the area. This area includes approximately 70 miles (113 km) of United States Highway 101; 70 miles (113 km) of State Routes 110, 112, and 113; and numerous local and other roads.

The Washington State Patrol has more-detailed data available for policing activities conducted by state troopers (Table 3-44). From 2018 to 2022, state troopers issued an annual average of approximately 53 traffic citations on the 36 miles (48 km) of state and federal highway closest to Neah Bay. This area includes United States Highway 101 between Forks and the turnoff for State Route 113, State Route 112 west of Sekiu, and the entire length of State Route 113. In addition to issuing tickets, state troopers responded to an average of 26 collisions in this area each year. In most years, the majority of these collisions occurred on the 11-mile (18-km) stretch of State Route 101 through Forks, which had an average annual rate of 1.6 collisions per mile. The corresponding rates

for United States Highway 112 and State Route 113 were 0.33 and 0.34 collisions per mile, respectively.

A law enforcement task force was assembled to ensure public safety during the previous hunts in 1998, 1999, and 2000 (Section 3.15, Public Safety, for more information about the task force). The task force was prepared to deploy any combination of 14 law enforcement agencies, from the Clallam County Sheriff's Department to the Royal Canadian Mounted Police. Ships, boats, planes, helicopters, squad cars, and the National Guard were prepared to participate, if necessary. The task force prepared for a worst-case scenario of 15 days of police protection, costing $160,000 in overtime, equipment, and supplies (Mapes 1998d). Despite serious concern about conflicts between protesters and whaling supporters, the full strength of the task force was never needed.

Source: Washington State Patrol 2023.

The Clallam County Sheriff's Department did not find that the hunt and associated activities imposed a substantial burden on department staff. Data from the Washington State Patrol indicate a spike in traffic stops on State Route 113 in 1999, which could be related to the Makah whale hunt (B. George, Washington State Patrol, pers. comm. October 27, 2005). Particular concern preceded the celebration of Makah Days in August 1998. There were rumors that up to 20,000 anti-whaling demonstrators might attend to disrupt the tribal community festival. Washington Governor Gary Locke mobilized 800 members of the National Guard to ensure public safety. By the end of the festival weekend, there had been no demonstrations and few protesters (Mapes 1998d). The following year, $825,000 of the state general fund was allocated to reimburse costs associated with this activation (Washington State Senate 1999).

3.14.3.3 Local Medical Facilities

The Sophie Trettevick Indian Health Center on the Makah Reservation employs physicians, a dentist, dental hygienist, and other practitioners (nurse practitioners, registered nurses, or public health nurses). The facility, operated by the Makah Tribe, provides comprehensive primary and dental health services. The clinic also has x-ray services and a pharmacy. The normal hours of operation are Monday through Friday, from 8:00 a.m. to 5:00 p.m. After-hours and emergency services are provided by emergency responders via 911 calls, 24 hours per day, 7 days per week. Emergency response includes stabilization and transport to the closest appropriate facility. Airlift Northwest (Seattle) can be called in, and patient destination is determined by the emergency responder. If Airlift Northwest is not available, the Coast Guard may provide transport. For emergencies on the water, the Coast Guard is the responder.

Although the health clinic provides day-to-day care service to tribal members, it will treat anyone with life or limb-threatening injuries. Injured non-Indian patients are stabilized and transported to an appropriate facility. The clinic has a memorandum of agreement with the Coast Guard to provide services and with Clallam Bay Fire District 5 to provide mutual assistance in emergency situations. The clinic has a Comprehensive Emergency Management Plan (2005) that dovetails to the Makah Comprehensive Management Plan (Subsection 3.1.2.2, Makah Tribal Programs and Management Plans).

The closest 24-hour medical facility is the Forks Community Hospital, approximately 50 miles (81 km) away. This is a Level 4 trauma care facility; patients with life-threatening injuries are stabilized and transported by Airlift Northwest or ambulance to more advanced trauma facilities, if necessary. The closest Level 3 trauma care facility (a facility with the resources for emergency resuscitation, surgery, and intensive care for most trauma patients) is at Olympic Medical Center in Port Angeles, 71 miles (114 km) from Neah Bay and 58 miles (93 km) from Forks. The closest Level 1-2 trauma care facility, which supports the full availability of specialists and can provide back-up resources for the care of exceptionally severe injuries, is Harborview Medical Center in Seattle, 120 air miles (193 air km) away.

3.15 Public Safety

3.15.1 Introduction

Aboriginal subsistence whale hunting is an inherently dangerous activity. The 2006 IWC Whale Killing Methods Workshop Report indicated, for example, that fatal accidents are not uncommon in Arctic aboriginal subsistence whaling hunts; between one and six people die annually in the Alaska and Chukotka Native hunts, combined (IWC 2007a). Five factors in the local environment

may affect public safety: location of the hunt; weather and sea conditions; behavior of the targeted species (the gray whale); number and behavior of people associated with the hunt (including protesters); and hunting equipment, including vessels and weapons. Some level of hunting currently exists on the Makah Reservation (e.g., for deer and elk), but the number of injuries associated with weapons accidents in hunting is unknown.

3.15.2 Regulatory Overview

3.15.2.1 Vessel Safety Regulations and Authorities

Any Makah whale hunt would occur within the EEZ of the United States, where the Coast Guard has enforcement authority over vessel safety under the Ports and Waterways Safety Act (33 USC 1221 *et seq.*). The Coast Guard has established an RNA in the Strait of Juan de Fuca and adjacent coastal waters of northwest Washington (33 CFR 165.1310) to enforce vessel activities near any Makah whale hunt and reduce the danger of loss of life and property from any hunt. Refer to Subsection 3.1.1.3, Coast Guard Regulated Navigation Area, and Figure 3-1. Designated and Managed Areas, for information about location of the RNA in relation to the action area. When the Coast Guard finalized the RNA after the 1999 hunt had occurred, it specifically found that "[t]he uncertain reactions of a pursued or wounded whale and the inherent dangers in firing a hunting rifle from a pitching and rolling small boat are likely to be present in all future hunts, and present a significant danger to life and property if persons or vessels are not excluded from the immediate vicinity of a hunt" (64 FR 61209, November 10, 1999).

Within the RNA, an MEZ is activated when one Makah whale hunt vessel displays an international numeral pennant 5. The whale hunt vessel may be a canoe or a motor boat and only one vessel may display the pennant; the MEZ extends 500 yards (457 m) around the vessel. The zone operates between sunrise and sunset, when surface visibility exceeds 1 nautical mile (33 CFR 165.1310(b)). The MEZ is deactivated upon sunset, when visibility is reduced to less than 1 nautical mile, or when the Makah hunt vessel takes down the international numeral pennant 5 (33 CFR 165.1310(b)). No person or vessel may enter the MEZ when it is activated, except for the authorized Makah whale hunt vessel, a preauthorized media pool vessel, or another vessel(s) or person(s) authorized by the Coast Guard (33 CFR 165.1310(c)), such as an observer vessel. The authorized media pool vessel must maneuver to avoid positioning itself between whales and hunt vessels, out of the line of fire, at a prudent distance and location relative to the whale hunt operations, and in a manner that avoids hindering the hunt or path of the whale in any way (33 CFR 165.1310(f)(3)). The media pool vessel must operate at its own risk, but in accordance with safety and law enforcement instructions from Coast Guard personnel (33 CFR 1310(f)). The

regulation does not affect normal transit or navigation in the RNA. The Makah whalers must provide specific broadcasts on a marine radio channel (Channel 16 VHF-FM), starting one-half hour before they begin whale hunting operations and continuing every half hour until hunting activities end. The broadcasts advise mariners of the 500-yard (457-m) exclusion area and urge them strongly to remain even further away from whale hunting activities as an additional safety measure (33 CFR 1310(e)).

The Coast Guard's regulations are consistent with the International Maritime Organization's guidelines for preventing collisions at sea (1972 Convention on the International Regulations for Preventing Collisions at Sea) and meet the goals of IWC Resolution 2006-2. At the 58th Annual Meeting on St. Kitts, the IWC adopted Resolution 2006-2 on the Safety of Vessels Engaged in Whaling and Whale Research-related Activities, recognizing concerns about confrontations related to whaling activities at sea and ports. The IWC and contracting governments acknowledged the right to legitimate and peaceful forms of protest and demonstration, but agreed and declared that the IWC and contracting governments do not condone any actions that are a risk to life and property relative to confrontations related to whaling between vessels at sea.

3.15.2.2 Weapon Safety Regulations and Authorities

For Makah tribal members on the Makah Reservation or hunting in the Tribe's U&A, Title 10 of the Makah Law and Order Code, Weapons Control Ordinance, governs the possession and use of weapons. Adults may possess weapons on the reservation, provided that individuals do not carry their weapons with intent to assault another, do not threaten to use or exhibit weapons in a dangerous or threatening manner, and do not use weapons in a fight or quarrel (Section 10.5.01). Weapons also must not be concealed; loaded and carried in a vehicle on a public road; discharged from, upon, or across any public highway (Section 10.5.01); and not possessed or discharged in any closed area (Section 10.5.02). Juveniles from 16 to 18 years of age may possess weapons after completing a weapons training course and receiving a weapons safety certificate from the chief of the Makah Tribal Police (Section 10.2.01).

Under the action alternatives and in the past hunts, the Tribe established certification guidelines and a certification process for all whaling team members with more in-depth training for captains, harpooners, riflemen, safety officers, and chase boat skippers to ensure that the hunt is carried out in as efficient, safe, and humane a manner as practicable. The guidelines and certification process ensure that every whaler has received adequate training to perform his assigned role on the team. Certification of riflemen includes a demonstration of proficiency and accuracy under simulated hunting conditions. Under the action alternatives, and in past hunts under the 2001 Gray Whale

Management Plan, the rifleman (onboard the Makah chase boat) cannot discharge a weapon until authorized to do so by a Makah safety officer. The primary safety measures, aside from standard weapon handling measures that apply, are:

1. The safety officer has the authority to determine whether visibility is less than 500 yards (457 m) in any direction, in which case the whaling captain suspends the hunt.
2. The safety officer would not authorize the rifleman to discharge the weapon unless the barrel of the rifle was above and within 30 feet (9.1 m) or less from the target area of the whale.
3. The safety officer would not authorize the rifleman to discharge the weapon unless the field of view is clear of all persons, vessels, buildings, vehicles, highways, and other objects or structures that if hit by a rifle shot could cause injury to human life and property.

Off the Makah Reservation (including on the territorial sea), or for non-Indians on the Reservation, the laws of Washington State apply to weapon possession and use. The Revised Code of Washington (3.1 RCW 9.41.270(1)) contains the following language:

> [i]t shall be unlawful for any person to carry, exhibit, display, or draw any firearm, dagger, sword, knife or other cutting or stabbing instrument, club, or any other weapon apparently capable of producing bodily harm, in a manner, under circumstances, and at a time and place that either manifests an intent to intimidate another or that warrants alarm for the safety of other persons.

3.15.2.3 Other Safety Regulations and Authorities

For Makah tribal members on the Makah Reservation or hunting in the Tribe's U&A, several different provisions of Title 5 of the Makah Law and Order Code, Criminal Code, prohibit acts such as assault, harassment, trespass, criminal mischief, and injury to public property, which could apply to disruptions associated with protest activities. Subsection 3.1.2.1, Makah Tribal Departments and Agencies, describes the Makah Public Safety Department, which is responsible for enforcing the Tribal Code, and Subsection 3.1.2.2, Makah Tribal Programs and Management Plans, describes the Makah Tribe's law enforcement programs. Off the Makah Reservation, or for non-Indians on the reservation, the laws of Washington State apply to such activities. The Revised Code of Washington prohibits a similar suite of criminal activities that could be associated with protest activities.

3.15.3 Existing Conditions

3.15.3.1 Location of the Hunt

The bulk of the Makah U&A lies along the geographically remote and isolated Pacific Ocean coast, but an arm of the U&A extends into the Strait of Juan de Fuca in United States waters from Neah Bay to Tongue Point near Port Angeles (Figure 1-1, Action Area). The portion of the U&A along the Strait of Juan de Fuca is less remote and is bordered by public lands, communities, and State Route 112, which runs parallel to the shoreline for nearly the entire length of the Strait portion of the U&A. A few points of State Route 112 closely hug the shore, but it is farther inland elsewhere. The current Coast Guard RNA is smaller than the U&A, and the portion of the RNA that extends into the Strait stops just past the Makah Reservation (Figure 3-1. Designated and Managed Areas).

3.15.3.2 Weather and Sea Conditions

3.15.3.2.1 Relevance of Weather and Sea Conditions

The IWC has recognized that prevailing weather conditions in association with relatively small vessels and traditional hunting techniques may diminish the efficiency of aboriginal subsistence whaling (see, for example, IWC Resolution 2001-2 and IWC Resolution 2004-3). Seasonal and weather variations in the local environment where aboriginal hunts occur also affect the safety of whale hunts, including locating, striking, and killing the whale; recovering the whale; and towing it back to a butchering location. In its Report on *Weapons, Techniques, and Observations in the Alaskan Bowhead Whale Subsistence Harvest*, the United States reported that fall bowhead hunts occur under conditions that include high winds, rough seas, and ice-choked waters and stated that fatal accidents are a fact of the hunt under such treacherous conditions (Alaska Eskimo Whaling Commission 2006). The weather and sea conditions in the action area can also be treacherous, as described further below.

Dangerous weather and sea conditions for the Makah historic whale hunts are evident in their traditional equipment design, such as 36-foot-long and five-foot-wide (11-m-long and 1.5-m-wide) canoes designed for seaworthiness and ability to travel great distances offshore (Arima 1983; Renker 2012), and in their statements before the British Commissioners in the 1890s, where tribal members reported that pelagic seal hunting was “practically given up” for about 20 years because of loss of lives at sea while hunting (Subsection 3.10.3.4, Makah Historic Whaling, Cessation of the Hunt, citing Crockford 1996). During the 1998 training exercises and the 1999 to 2000 Makah whale hunts, no weather-related accidents or fatalities occurred. All hunts occurred in late April and May, when weather and seas generally begin to improve in the Makah U&A. On

May 11, 1999, the Makah suspended one of their 4 days of hunting for that year after less than 2 hours of hunting because of inclement weather conditions (Gosho 1999; NMFS 1999). During the fall/winter of 1999/2000, the Makah Tribal Council did not issue any whaling permits because weather conditions were unsuitable.

Relevant weather and sea-state parameters for the action area and action alternatives include air temperature, sea temperature, fog and precipitation, wind speed, and wave height. Air temperature is important to hunting safety because ocean water can freeze on deck (generally at 28.5 °F [-1.9 °C]), potentially causing equipment to be slick or otherwise hampered. This could lead to injuries or reduce the accuracy and efficiency of the harpooner and rifleman. Sea temperature may also be relevant to determining the risk of hypothermia if a person involved in or protesting the hunt enters the water (for example as the result of a boat overturning or other accident). Fog and precipitation can reduce visibility, creating a potential for vessel collisions or reducing the accuracy of the harpooner or rifleman. Beattie (2001) recommended a minimum visibility standard of 500 yards (457 m) in all directions during the Makah hunts to eliminate problems with boats entering the 500-yard (457 m) MEZ (Subsection 1.4.2, Summary of Recent Makah Whaling — 1998 through 2007, for information about the many boats that have been associated with past Makah hunts). The Makah included this 500-yard (457 m) visibility recommendation in their proposed action. Wind speed can also affect the accuracy of the harpooner or rifleman.

Wave height can affect vessel operations and stability, as well as visibility and orientation of the whale, all of which can influence the accuracy of the harpooner or rifleman. Beattie (2001) recommended that the Makah hunts institute a 30-foot (9.1-m) distance limitation between the rifleman and the whale and require that a rifleman only fire at a downward angle, based on concerns about sea swell as it relates to accuracy (i.e., missed shots) and ricochets. The Makah's proposed action includes the 30-foot (9.1-m) distance limit and downward firing angle. In a later report, again examining the safety and guidelines for the Makah hunt, Graves et al. (2004) concluded that shots fired below an elevation angle of -6.2° (that is, with the gun pointed downward at the target in the water and below the shooter's horizon by at least 6.2 degrees) will ensure a very low probability of ricochets, "whether the water surface is glass smooth or rough with waves" (Subsection 3.15.3.5.2, Weapons Associated with the Hunt, Secondary Killing Methods).

3.15.3.2.2 Description of Weather and Sea Conditions in the Action Area

Wind direction, ocean surface temperatures, terrain, and the intensity of high and low pressure centers over the North Pacific Ocean produce a marine climate in the action area characterized by distinctive seasons marked by highly variable weather (U.S. Department of Agriculture 2013; National Park Service 2013). Table 3-45 displays precipitation levels at Tatoosh Island, visibility (fog) ratings at the Quillayute Airport[80], and air and sea temperatures, wind speeds, and wave heights measured at the Strait of Juan de Fuca Traffic Separation Lighted Buoy ("J buoy") anchored 7 miles (11.4 km) north of Tatoosh Island.

Variations in air and sea temperatures and precipitation follow a seasonal pattern. Daily average air temperature drops steadily from August through January, with warming beginning in February and continuing through July. Daily average air temperature ranges from around 43 °F (6 °C) in January to around 55 °F (13 °C) in July. Sea temperature follows a similar pattern, ranging from an average daily low around 46 °F (8 °C) in February to around 53 °F (12 °C) in July and August. Measurable precipitation occurs on approximately 200 days each year, with annual average precipitation amounting to around 78 inches (2 m) and nearly half of that occurring in the 3 months of November through January. The summer months of July and August are usually the driest; however, heavy fog (the other factor affecting visibility) also typically occurs during the late summer. The period from May through July tends to have the fewest heavy fog days combined with relatively low precipitation.

Winds in the action area are strongest from November through March, when daily average wind speeds range from 11.1 to 14.4 knots (5.7 to 7.4 m/s). Winds typically taper off in the spring, and during the summer months of June through August average wind speeds decline to 5.4 to 6.2 knots (2.8 to 3.2 m/s) and gale-force gusts[81] are absent. Gale-force gusts begin to recur in September and wind speeds increase steadily to peak average and maximum values during the winter. Wave heights follow a similar pattern, with lowest heights around 4 feet (1.2 m) during the summer months of June through August and highest around 8 feet (2.4 m) during the winter

[80] The Quillayute Airport is located approximately 9 miles (14.5 km) south of the proposed hunt area but is the closest climatological station reporting visibility data (i.e., number of days with heavy fog). Although the airport is approximately 3 miles (4.8 km) inland from the coast, the monthly patterns of heavy fog days are similar to other coastal stations much farther away from the proposed hunt area (e.g., Port Angeles and Hoquiam, Washington).

[81] The National Weather Service (2013) defines a gale as sustained surface winds of 34 to 47 knots (18 to 24 m/s).

months. Maximum wave heights can approach 33 feet (10.1 meters) during the month of December.

According to the Tribe's marine mammal biologist, wave height and wind speed are two of the most important variables likely to affect a whale hunt (J. Scordino, Makah Tribe Marine Mammal Biologist, pers. comm., July 31, 2013). Based on experience during hundreds of boat-based marine mammal surveys in the Makah U&A, the Tribe's biologist estimated that the best chances for small vessels to pursue a gray whale in coastal waters would occur when wave heights are less than 6 feet (1.8 m) and wind speeds are less than 16 knots (8.2 m/s). Using data from the J buoy off Cape Flattery (NOAA National Data Buoy Center 2013), Table 3-45 summarizes the percent of monthly observations that exceed these values, while Figure 3-15 displays a synthesis of the available data to estimate the number of days with both favorable wind and wave conditions (i.e., at or below the stated values). Inclement weather during November to March would likely result in only 5 to 7 days with favorable conditions per month (on average) during that period, followed by an increase to 13 to 23 days per month in April and May. Nearly every day during June through August would present favorable conditions, after which hunters might encounter 12 to 21 days with favorable conditions during September and October.

Table 3-45. Climatological data from stations in the vicinity of the proposed hunt area.

3.15.3.3 Behavior of the Gray Whale

Early whalers referred to gray whales as 'devil fish' and 'hard head' because gray whales were reported to attack whaling skiffs when harpooned, frequently causing a loss of human life (Henderson 1984). During the IWC's 2003 workshop on whale killing methods, the Russian delegate emphasized the aggressive behavior of gray whales (IWC 2004c), and such behaviors continue to be reported during hunts by Chukotkan natives (e.g., IWC 2012i). The violent struggles of a struck whale can result in vessels being capsized, persons on vessels being knocked into the water (Alaska Eskimo Whaling Commission 2006), or individuals becoming entangled in the lines fastened to the whale. Even postmortem movements of a whale may be dangerous. Towing a dead whale also presents hazards, particularly if the whale is not well moored to the vessel (Alaska Eskimo Whaling Commission 2006). While the Makah hunts in 1998 through 2000 did not result in any fatal accidents, hunting disasters did occur in prior whaling days. Arima (1983) reported that, "[t]he dangerous [moments of the hunt] lasted until all the line and

floats were . . . out because someone could get caught in a loop or the canoe could be capsized or smashed in the first violent struggles of the whale before it sounded."

3.15.3.4 Behavior of People Associated with the Hunt

Based on experience in the 1998 Makah training exercises and the 1999/2000 hunts, any future Makah whale hunting will likely generate some degree of public interest that may involve public protests and the media. For additional information, see Subsection 1.4.2, Summary of Recent Makah Whaling–1998 through 2007, and Subsection 3.12.3.3, Media Coverage of the 1998 through 2000 Hunts.

Before the Makah began the gray whale hunt in 1998, law enforcement authorities had advance notice of likely protests and conflicts between those protesting and those supporting the hunt. Prior to the hunt, the Makah Tribal Council directed the Makah Police Chief to form a task force of Makah departments (including the Police Department and Health Clinic) and off-reservation public safety resources (including Washington State Patrol, Clallam County Sheriff's Office, Coast Guard, Federal Bureau of Investigation (FBI), Department of Defense, other tribal police departments, etc.) to recommend a strategy to address any potential public disturbance related to whale hunts. The strategy called for close coordination of tribal, state, and federal authorities, including the military (Subsection 3.14.3.2, [Public Services] Police, for more detail). The following discussion summarizes the protest activities and conflicts before and during the 1998 to 2000 whale hunts, including law enforcement response.

In 1998, the Makah whaling crew began to prepare for a hunt scheduled to start October 1, 1998. On August 25, 1998, the Makah Tribal Council passed Tribal Resolution 189-98 stating that protest vessels were not to dock at Neah Bay. This meant that protesters were not to attempt to disembark from vessels. A flotilla of protest vessels began to arrive before October 1, anchoring offshore in Neah Bay near Waadah Island. It included zodiacs, kayaks, a few larger boats belonging to the Sea Shepherd Conservation Society, and a two-person Norwegian Navy surplus submarine, painted like a killer whale and intended to deliver killer whale calls into the water to scare gray whales away. Federal and state officials advised the Sea Shepherd Conservation Society that noise emitted by the killer whale submarine might constitute harassment under the MMPA (Victoria Times Colonist 1998). Others moored in nearby Sekiu, away from the reservation. The Sea Shepherd Conservation Society coordinated volunteers to conduct scouting trips up and down the coast in 15 boats, watching for the whaling canoe (Mapes 1998e). A British Columbia whale-watching charter organization representing 10 firms also appeared on October 1

(Mapes 1998e). By October 8, the protest vessels had deployed twice in reaction to a false alarm that the Makah were hunting whales (Mapes 1998e).

On November 1, 1998, one of the protesting organizations (Sea Shepherd Conservation Society) notified the Makah Tribal Council and law enforcement officials that a staged demonstration would take place. Coast Guard and Clallam County Sheriff's Office personnel remained at the Coast Guard base in Neah Bay but stayed in contact with Neah Bay Police, who took the lead according to the previously agreed upon task force structure. The M/V *Sirenian*, one of the larger boats, was steered up near the boat dock, and several zodiacs, kayaks, and jet skis approached and sped around inner Neah Bay. The protest boats played killer whale vocalizations over a loudspeaker and blew air horns (Mapes 1998f), shouted at tribal members onshore, and displayed protest banners. Crowds of Makah tribal members assembled on the waterfront, in cars and on the shore, exchanging insults and honking horns; several members beat tribal drums, danced, and sang songs (Mapes 1998f; Shukovsky 1998a). Some Makah youths ran out on the docks with firecrackers and rocks, throwing them at the protest vessels, breaking a window on the *Sirenian*. Three protesters in a zodiac attempted to dock the vessel (to accept a dinner invitation from a Makah member); someone pushed one of the protesters off the dock into the water, without injury (Lacitis 1998; Mapes 1998f). Neah Bay Police subsequently detained all three protesters (Mapes 1998f). Tribal members and the police confiscated the zodiac; a fourth protester waded ashore to retrieve the zodiac and was arrested. The Neah Bay Police turned all the detained individuals over to the Clallam Bay Sheriff's Office. The protesters all gave voluntary statements and were released without charges (Mapes 1998f). The tribal police established order on shore, and the crowd dispersed. Clallam Bay Sheriff's Department and the FBI conducted investigations in the following days (Mapes 1998f; Shukovsky 1998b).

A group of 30 protesters attempted a simultaneous vehicle protest on State Route 112, but Neah Bay Police stopped the protesters at the reservation boundary (Mapes 1998g). On November 5, Jean-Michel Cousteau visited the Makah Reservation and asked the Makah not to hunt; the visit was cordial by all accounts (Shukovsky and Barber 1998). On November 11, 1998, protest vessels mobilized but were responding to a false report that the Tribe was hunting and had killed and landed a whale (U.S. Coast Guard 1998). Talks between the leader of the Sea Shepherd Conservation Society and the Makah Tribal Council took place on November 24, 1998. Sea Shepherd reportedly assured the Makah that motivations were not racial, and the Makah reportedly assured Sea Shepherd that they did not intend to sell whale meat to Japan (Denn 1998a). All the protest vessels left by November 26, 1998 (The Edmonton Journal 1998). A

second group of anti-whaling activists offered the Tribe monetary compensation in lieu of whaling (Denn 1998b), but the Tribe did not accept the offer (Denn 1998c).

The spring 1999 hunt began on May 10, 1999, and continued over 4 nonconsecutive days (May 10, 11, 15, and 17) in the coastal portion of the Makah U&A south of Cape Flattery (Subsection 1.4.2, Summary of Recent Makah Whaling, for a more complete description of hunting locations). On May 10, 1999, the hunt was disrupted by vessel-based protesters who maneuvered between the two Makah vessels and the whales. Protesters tried to scare the whales, and they also fired flares and smoke flares at the Makah whaling party vessels (NMFS 1999; Sunde et al. 1999; U.S. Coast Guard 1999a). Because most of the hunting occurred south of the Coast Guard's RNA, a 500-yard (457 m) MEZ around the Makah vessels was not in effect (NMFS 1999). Coast Guard officials detained two of the protesters and subsequently cited them for grossly negligent operation. The Clallam County sheriff arrested them for reckless endangerment (NMFS 1999; Sunde et al. 1999; U.S. Coast Guard 1999a). On May 11, the Makah whaling captain called off the second hunt shortly after it began because of inclement weather.

On May 15, 1999, protest vessels operated around the whalers much of the day. Two protest vessels struck whales. One vessel ran over the top of a whale and temporarily stunned it, while another vessel hit the flukes of a diving whale beside the Makah canoe (NMFS 1999). The Coast Guard cited four vessels for grossly negligent operations and/or MMPA infractions and took three of the vessels into federal custody (NMFS 1999). On May 17, 1999, the fourth and final day of the hunt, no protest vessels attempted to disrupt the hunt (U.S. Coast Guard 1999b). The Makah crew successfully landed a whale on that day. Local and regional anti-whaling activists engaged in various acts of protest after the successful 1999 hunt. Activities ranged from peaceful candlelight vigils in Seattle (Burkitt 1999b) to protests on Washington State Route 112 at the Makah Reservation boundary. The leaders of some activist groups encouraged more direct action, such as being arrested, using lock boxes (barrels filled with concrete), and lock downs (use of chains, pipes, etc. to lock individuals together) (U.S. Coast Guard 1999c).

Before the spring 2000 hunt began, protesters arrived, patrolling the coast in a 38-foot (12-m) retired Canadian search-and-rescue vessel equipped with two jet skis and carrying some of the activists who had been charged in 1999 with negligently operating a motorized vessel (Welch and Morris 2000). A group of 30 protesters also blocked road access to the Makah Reservation for about an hour in early April (Welch and Morris 2000). The spring 2000 hunt began on April 17, 2000 and covered seven nonconsecutive days (April 17 and 20; May 6, 7, 10, 12, and 29) in the coastal portion of the Makah U&A south of Cape Flattery (Subsection 1.4.2, Summary of Recent

Makah Whaling, for a more complete description of hunting locations). All hunts occurred within the Coast Guard's RNA and MEZ (Gearin and Gosho 2000), unlike spring 1999 hunts, because the southward boundary of the RNA had been extended by final rule on November 10, 1999 (64 FR 61209). During the first 2 days of hunting (April 17 and 20), protesters disrupted the hunts (Gearin and Gosho 2000). On April 21, Coast Guard personnel boarded two protest vessels and issued warnings (United States Coast Guard 2000). One of the vessels entered the 500-yard (457-m) MEZ on three occasions subsequent to the Coast Guard advisory and was intercepted and again warned by the Coast Guard (United States Coast Guard 2000). On at least one of these three entrances into the MEZ, the vessel entered the 500-yard (457-m) MEZ at high speed and was intercepted within 50 yards (46 m) of the Makah's canoe (Gearin and Gosho 2000). Two individuals on jet skis also entered the MEZ, making high-speed charges at the Makah canoe (U.S.Coast Guard 2000). The Coast Guard intercepted both jet skiers. One jet-ski operator collided with a Coast Guard vessel and sustained shoulder injuries; Coast Guard personnel retrieved the individual from the water, placed the person under arrest, and transported her to Olympic Memorial Hospital (U.S. Coast Guard 2000). The Coast Guard also intercepted and arrested the second jet-ski operator, transferring the individual to the Clallam County Sheriff's Office (U.S. Coast Guard 2000). On the 5 remaining hunting days (May 6, 7, 10, 12, and 29, 2000), one to three protester vessels were present during hunting, but they did not enter the MEZ to disrupt whale hunting.

3.15.3.5 Hunting Methods

3.15.3.5.1 Vessels Associated with the Hunt

The Makah traditionally hunted whales from large canoes approximately 36 feet (11 m) long and more than 5 feet (1.5 m) wide. Carvers made the canoes from a single cedar log. In present days, the Makah use both dugout and strip canoes for canoe journeys, canoe races, and other canoeing activities. In the waiver request, the Makah proposed to make the initial approach and strike the whale in their traditional hunting canoe. A more modern chase vessel (a small skiff equipped with an outboard motor) would follow the traditional canoe. The second vessel would provide a platform for tribal members (a rifleman, safety officer, and observer) who would assist in the hunt by applying additional harpoons if needed, killing a struck whale, finding a struck and lost whale, or towing a killed whale to shore. The driver of the chase boat would maneuver the rifleman to the harpooned whale to deliver a rifle shot at distances less than 30 feet (9.1 m) from the target area.

3.15.3.5.2 Weapons Associated with the Hunt

Traditionally, the Makah used wooden harpoons with mussel shell tips to strike whales. The harpoon was attached to sealskin floats and lines made of sinew and cedar to secure whales. A long wooden lance was used to kill whales. After contact with American whalers, the Makah began to use iron harpoon heads and accept tows from commercial steamers. The Makah propose to hunt gray whales using a toggle-point steel harpoon, with a rope and floats attached, to strike and secure the whale and a .50 caliber rifle to kill it. This FEIS evaluates a .577 caliber rifle as an alternative rifle to kill a whale and a darting gun (with penthrite grenades) as an alternative to strike and kill a whale.

Primary Weapon Used to Strike (and Potentially Kill) Whales

Toggle-point Harpoon

A toggle-point harpoon is a wooden or metal shaft with a movable point (head) and is usually attached to a line (rope) and float. When the harpoon is thrust into a whale, the point twists horizontally (toggles) under the animal's skin. Pulling on the attached line secures the harpoon to the whale. The harpoon probably would not kill the whale, but it would be used initially to strike and secure it with the line and floats. The Makah used a toggle point harpoon with a stainless steel point to strike and secure the whale during the 1999 hunt, and their proposal is to continue using this method of striking whales.

Darting Gun (with toggle-point harpoon plus black powder or penthrite explosive projectiles)

A darting gun is a primary weapon some subsistence hunters use to strike and potentially kill whales. It is thrown by hand and consists of a steel toggle-point harpoon (connected to a line and floats) with a barrel attached to hold an explosive projectile (also referred to as a grenade, explosive charge, super bomb, and bomb lance) (O'Hara et al. 1999; Alaska Eskimo Whaling Commission 2004). A more extensive discussion of the types of explosive projectiles used in whaling follows. The steel harpoon serves the same purpose as the toggle-point harpoon described above, attaching a line and floats to the whale (and it may be desirable to attach additional floats using a toggle-point harpoon to keep a struck whale from sinking). The explosive projectile has a time-delay fuse designed to detonate after penetrating the whale; it is intended to stun or potentially kill the whale in conjunction with the first strike. Whales not killed by this first strike are killed using secondary weapons (another strike with the darting gun or the shoulder gun).

Secondary Weapon Used to Kill Whales

For most aboriginal whale hunts, secondary weapons (defined as those following the primary strike) are required to kill the whale. Secondary methods used by subsistence hunters include making additional strikes with the darting gun, shooting high caliber rifles, or firing explosive projectiles from a shoulder gun. The IWC encourages hunters to use secondary weapons for animals that move or in other ways show any signs of life as a routine precaution (IWC 2007a). The IWC has identified the appropriate target area for whales killed with rifles as the brain case (brain and upper neck) and, in emergencies, the heart. For whales killed with explosive projectiles, the appropriate target areas are the thorax and neck (IWC 2007a).

High Caliber Rifle

Several aboriginal subsistence whalers and some commercial whalers use rifles as the secondary killing method. In 1997 and 1999, the Makah Whaling Commission contracted with Dr. Allen Ingling, a University of Maryland veterinarian with a background in ballistics, to choose the optimal weapons for hunting gray whales. The Tribe's goal was to provide safe conditions for humans and to employ a humane, effective, and efficient method of killing gray whales once attached to a line and floats. Dr. Ingling and the Makah investigated the performance of several firearms, including the Garand 30'06, Winchester .458 Magnum, Weatherby .460 Magnum, State Arms and LAR .50BMG, and the .577 A-Square Tyrannosaur. Participants assessed the weapons for efficiency, safety, and humaneness by testing the depth of penetration of bullets in a water tank and evaluating weight, recoil, and loading ease (Ingling 1997; Ingling 1999). All of the weapons could kill a whale, based on test results, but participants selected the highest caliber rifles, the .50BMG and .577 A-Square Tyrannosaur, as the best options (Ingling 1999), primarily because the bullets would penetrate deeper in water, allowing a larger margin of error in targeting. The Tribe ultimately used the .577 A-Square Tyrannosaur in the 1999 hunt, because it was 6 pounds (2.7 kg) lighter that the .50BMG, it had a 3-round rather than single-shot capacity, and its shots reached the maximum penetration in water tank tests (Ingling 1999).

In NMFS' 2001 EA (NMFS 2001a), reports indicated that no data on ricochet were available from the Army's .50BMG Field Manual (United States Army 1991). During a public comment period, NMFS received a report from Kline Engineering Company (Kline 2001) that assessed ricochet data, ricochet probability, and modeled trajectories for .50 caliber M33 rounds fired against sand. Kline (2001) concluded that no firings should be conducted within 6,670 yards (6,099 m) from shore and advised that a ricochet could travel almost 1,860 yards (1,700 m) off the line of fire. Subsequent to the Kline report, Beattie Natural Resources Consulting assessed the public safety of the 1999 hunt, specifically, the potential for injury or death from rifle fire to non-

participants in the hunt. Beattie (2001) disagreed with Kline's earlier conclusions about a safety zone but agreed there was a potential for missed shots to ricochet. Beattie (2001) made the following recommendations to enhance public safety of the hunt in the Strait of Juan de Fuca:

- Riflemen should have to use either a .50 caliber or .577 caliber rifle as the primary rifle.
- A rifleman should not shoot if the intended target is more than 30 feet (9.1 m) from the muzzle of the rifle [to ensure that misses do not occur and to reduce the possibility of a ricochet].
- A rifleman should fire only at a downward angle [because a harpooned whale could surface at the top of a swell while the chase boat was in a position toward the middle of the trough or swell. In that situation, firing a shot might result in the unimpeded travel of the projectile toward the boundary of the MEZ, should the shot miss the whale and water].
- The Makah Whaling Commission should use simulated hunting conditions to document the riflemen's proficiency using rifles actually employed during whale hunting.
- There must be minimum visibility of 500 yards (457 m) in all directions when it is harpooned (to eliminate problems with the boats entering the 500-yard (457-m) MEZ because of low visibility).
- Where Highway 112 closely parallels the shoreline, the rifleman on the chase boat should fire at a whale with the rifle pointed away from the shoreline if the harpooned whale is within 500 yards (457 m) of the shoreline.
- The diver on the chase boat should be the designated safety officer for the hunt (because the diver does not have another assignment or responsibility until others kill the whale). The diver should be assigned the sole task of monitoring safety conditions within the MEZ to ensure that the rifleman has a clear field of fire.

In 2004, NMFS contracted experts in military firearms training and technological capabilities to review all relevant public safety issues surrounding the conduct of Makah whale hunts, including the information presented in Kline (2001) and Beattie (2001). These experts confirmed the selection of the .50 caliber rifle as the weapon of choice, over the .577 A-Square, because it combines high power with consistently manufactured, commercial grade ammunition (Graves et al. 2004; Graves and Hazelton 2004). Graves et al. (2004) also conducted ricochet and range experiments on still water using similar weapons. They concluded that shots fired below an elevation angle of -6.2° (that is, with the gun pointed downward at the target in the water and below the shooter's horizon by at least 6.2 degrees) will ensure a very low probability of ricochets. Moreover, the probability of a ricochet declines to zero when shots are kept below the

elevation angle, but wave height is greater, because wave changes in the surface geometry vastly reduce the surface area (i.e., wave tops) that can cause ricochets (Graves et al. 2004). Graves et al. (2004) also recommended that all persons near the hunt wear eye and double ear protection (i.e., earplugs and shooting muffs) when firing the rifle. This recommendation might conflict with that of Beattie (2001), which requires the rifleman to communicate verbally with the safety officer.

Explosive Projectiles (grenades)

Explosive projectiles for killing whales may contain either black powder or penthrite. Currently, only darting guns have been modified to accommodate penthrite projectiles. The projectile is aimed at the neck and thoracic regions and kills the whale by damaging internal organs, either with the shock wave of the blast or tearing of tissues and hemorrhage caused by shrapnel (O'Hara et al. 1999). For each type of grenade, whether used with a hand-thrown darting gun or a shoulder gun, the grenades are very similar in shape (Øen 1995).

Black powder grenades are approximately 11.2 inches (28 cm) long and 0.9-inch (.2 cm) in diameter. The black powder in the grenade is a mixture of sulfur, saltpeter, and charcoal (Øen 1995; O'Hara et al. 1999), which explodes when ignited. Alaska Natives have used black powder grenades in hand-thrown darting guns in the bowhead hunt for approximately 150 years (Alaska Eskimo Whaling Commission 2006) and more recently in shoulder guns. The grenade's time-delayed fuse is designed to ignite in the barrel and detonate the grenade after it enters the whale's body. If the gun jams or the projectile detonates prematurely, it can cause a dangerous explosion on the whaling vessel (O'Hara et al. 1999). Øen reported that 18 percent of the black powder grenades malfunctioned (1995) in the 1984 to 1986 bowhead hunting seasons, though he did not describe the nature of the malfunctions. Black powder burns slowly, and less than half converts to gas (North Atlantic Marine Mammal Commission 2004). Black powder is also very sensitive to friction and electricity. Several accidents have occurred during production and the use of black powder. It is now classified as explosive, and storage and sale are entirely banned in some communities (North Atlantic Marine Mammal Commission 2004).

The penthrite grenade uses penthrite as the explosive material. A penthrite grenade consists of a tubular body that holds a charge (the penthrite), has a head with a firing mechanism, and contains safety devices. The time-delayed fuse on the penthrite grenade ignites after the grenade penetrates the whale, in contrast to the black powder grenade, which ignites in the barrel, reducing the risk of an explosion on the whaling vessel (Øen 2000). Numerous other grenade safety features are intended to prevent injury to whalers (Øen 2000). Penthrite combusts nearly instantaneously and

provides substantially larger explosive power than black powder (Øen 2000). Reflecting use of advanced design and materials, a single penthrite projectile currently costs $1,000 (Alaska Eskimo Whaling Commission 2023).

The Alaska Eskimo Whaling Commission Weapons Improvement Program Committee worked with cooperating scientists from Norway on the design, testing, and manufacture of penthrite between 1987 and 1998. The participants' intent was to adapt penthrite grenades used in commercial whaling for use in the darting guns used by Alaska whalers (Alaska Eskimo Whaling Commission 2006). In 2004, the Alaska Eskimo Whaling Commission, working in conjunction with the Norwegian government, developed a safety handbook and training video regarding the function and proper use of the penthrite projectile. Whaling captains must complete training and obtain certification in the use of the penthrite projectile and modified darting gun barrel. The Alaska Eskimo Whaling Commission conducts ongoing trainings for whaling captains and crew members on the safe use of penthrite projectiles through their Weaponse Improvement Program (IWC 2016).

It is uncertain whether penthrite grenades would be readily available for a Makah Tribe gray whale hunt. As noted above, the projectiles are expensive and the new darting guns can also cost approximately $1,000 apiece, not including extremely high shipping costs (IWC 2012h). It is also unclear how easily the Tribe could obtain the grenades; currently the Alaska Eskimo Whaling Commission imports its penthrite projectiles from a Norwegian manufacturer, but is consulting with the U.S. Department of Homeland Security and the Bureau of Alcohol, Tobacco, and Firearms to determine if it is possible to manufacture them domestically (IWC 2012h; Alaska Eskimo Whaling Commission 2023).

Some aboriginal subsistence whalers use shoulder guns to deliver explosive projectiles intended to kill a whale that has already been struck with a harpoon with an attached line and floats. A shoulder gun is generally a smooth bore seven or eight gauge weapon fired from the shoulder like a shotgun. Like a shotgun, it uses gunpowder to launch the projectile at the target. Although Øen (1995) recommended development of a shoulder gun capable of delivering a penthrite grenade, no shoulder guns adapted for this projectile currently exist.

3.16 Human Health

3.16.1 Introduction

The following sections describe health-related issues related to the handling and eating of whales and whale food products.

3.16.2 Regulatory Overview

The Makah Tribal Council has developed a health code in recognition of the need for delivery of comprehensive health services to tribal members and their families. Title I, Policy, states that these codes apply uniformly throughout the Makah Indian Reservation to help tribal members achieve the health status of the general population and to increase effectiveness and efficiency of services offered within the reservation. The Makah Health Code offers a framework for decision-making related to health issues. None of the provisions relates to subsistence use of whales.

3.16.3 Existing Conditions

3.16.3.1 Nutritional and Health Benefits from Consuming Whale Food Products and Other Traditional Subsistence Foods

Historically, whale oil and whale products were important nutritional components of the diet of the Makah Tribe. They also played an important role in the Makah's cultural and spiritual well being (Subsection 3.10.3.5, Contemporary Makah Society, for a description of the Makah Tribe's subsistence consumption). Whale oil, in particular, was widely used, because it did not spoil as quickly as whale meat. Early archaeological studies indicated that as much as 84 percent of the Makah diet was whale meat, oil, and other food products (Huelsbeck 1994). The Makah currently and historically have used the following whale products (Renker 2018): raw blubber, oil rendered from whale blubber, organ meats (e.g., brain, heart), and muscle tissue from all parts of the whale (including around the jaw and under the eye). They use the rich oil for cooking and flavoring foods, as well as for ceremonial purposes (Renker 2018).

The introduction of the western diet (i.e., refined sugar and flour, beef, vegetable oil and lard, etc.) and the reduction in subsistence foods have been linked to poor health in Native American populations (Budowski 1988; Simopoulos 1999; Renker 2018) and also in Alaska Natives (IWC 1979b; Ebbesson et al. 2005a; AMAP 2021). The Makah Tribe, however, continues to consume large quantities of marine fish and shellfish, and this longstanding reliance on marine foods (including whale products) resulted in a diet with a narrow nutritional base. On average, Makah consume 126 pounds (57 kg) per capita per year (5.5 ounces [156 g] per day) of finfish and shellfish (Sepez 2001). Sepez (2001) also calculated that the whale products (blubber and meat) consumed in 1999 equaled about 2.4 pounds (1.1 kg) per capita and that an additional amount was consumed at the community potlatch. For comparison, Renker (2018) calculated that harvesting an average of five gray whales per year would yield 8 to 20 pounds (4 to 9 kg) of meat per Makah and 16 to 20 pounds (7 to 20 kg) of oil or blubber per Makah (and a somewhat smaller amount of whale oil after rendering).

General nutritional components of whale meat[82] and other protein sources are compared in Table 3-46. Nutritional data are from the United States Department of Agriculture National Nutrient Database for Standard Reference (U.S.Department of Agriculture 2019). With the exception of whale oil and blubber, whale products have a similar nutritional profile (e.g., calories, protein, fat, and calcium) as other finfish, shellfish, wild game, and domestic meats. Whale oils and blubber provide a richer source of energy (calories) than other food types listed in Table 3-46, and whale meat has higher levels of iron. Whale oil is a good source of vitamin E (an antioxidant) and whale meat is a good source of selenium, both of which may play a role in protecting against the toxicity of certain seafood contaminants like mercury (Arnold and Middaugh 2004; AMAP 2021). Overall, however, it is difficult to compare essential nutrients and minerals of whale products directly to other protein sources because the former have not been studied extensively.

In addition to providing protein and energy, marine foods also contain essential vitamins, minerals, and lipids. Essential lipids include polyunsaturated fatty acids, which are important components of both whale and fish oils and are high in omega-3 polyunsaturated fatty acids (e.g., alpha-linolenic acid, eicosapentaenoic acid, docosapentaenoic acid, and docosahexenoic acid). These essential fatty acids improve or prevent symptoms associated with coronary heart disease, hypertension, Type 2 diabetes, kidney disease, rheumatoid arthritis, Crohn's disease, and chronic obstructive pulmonary disease (Budowski 1988; Simopoulos 1999; Simopoulos 2002; Holub and Holub 2004; Ebbesson et al. 2005a; Ebbesson et al. 2005b; Ebbesson et al. 2005c; Reynolds et al. 2006).

The human body does not naturally produce essential polyunsaturated fatty acids, so they must come from food consumed. Polyunsaturated fatty acids exist in a variety of food sources, including fish oils, vegetable oils (e.g., soybean), nuts, and meat from terrestrial or marine mammals (e.g., whales), and vitamin supplements (National Academy of Sciences 2005).

Studies of subsistence populations that consume higher quantities of seafood than the general United States population, and consequently ingest higher levels of omega-3 fatty acids, suggest that these populations have lower rates of heart disease than the general population (Dewailly et al. 2001; McLaughlin et al. 2005). For example, McLaughlin et al. (2005) found that

[82] Whale food products' nutritional information shown in Table 3-46 includes data for bowhead and minke whales (both baleen whales like the gray whale) and beluga (a toothed whale distinct from baleen whales).

Alaska Natives with high dietary intake of polyunsaturated fatty acids (evidenced by higher tissue levels of polyunsaturated fatty acids) had lower heart disease mortality than non-natives.

Ebbesson et al. (2005b) measured fatty acid concentrations in Norton Sound (Alaska) Eskimos and screened for insulin resistance and diabetes. Findings indicated that high consumption of omega-3 fatty acids positively affected insulin sensitivity and glucose tolerance. Osterud et al. (1995) studied healthy men and women given supplements of oils (15 milliliters [mL]/day) from the blubber of seal, cod liver, and Minke whale for 10 weeks. Supplementation of the diet, especially with whale oil, had beneficial effects on biological measures associated with cardiovascular and thrombotic diseases.

Reynolds et al. (2006) reported on the high levels of omega-3 fatty acids in bowhead whale blubber consumed by Alaska Natives. The high levels of omega-3 fatty acids in the blubber and other marine mammal food products confer considerable health benefits on subsistence consumers and are important in the treatment or prevention of insulin resistance, diabetes, elevated blood pressure, cardiovascular disease, arthritis, and stroke (Reynolds et al. 2006).

Seafood diets containing essential polyunsaturated fatty acids are also beneficial for women at risk for hypertension during pregnancy (Popeski et al. 1991) and may prolong gestation and increase birth weight (Olsen et al. 1993; Grandjean et al. 2001). There was, however, a limit to the observed positive effects on birth weight, as researchers did not find increased weights at higher intake levels (greater than three fish meals per week) of essential fatty acids (Olsen et al. 1993; Grandjean et al. 2001). The National Academy of Sciences (2013) recommends dietary intake of polyunsaturated fatty acids (i.e., alpha-linolenic acids) at 0.5 grams/day (infants), 0.7 to 0.9 grams/day (children), and 1.0 to 1.6 grams/day (adults).

Table 3-46. U.S. Department of Agriculture (USDA) nutritional values for selected food types.

Food Type	Energy (calories /100g)	Protein (g/100g)	Calcium (mg/100g)	Iron (mg/100g)	Selenium (µg/100g)	Vitamin A (IU/100g)	Vitamin E (mg/100g)	Vitamin B6 (mg/100g)	Vitamin B12 (µg/100g)	Total Fat (g/100g)	Total Saturated Fat (g/100g)	Total Mono-unsaturated Fat (g/100g)	Total Poly-unsaturated Fat (g/100g)

[1] This type of tissue is referred to by several different names (population specific), including maktak, muktuk or mattak. (g) = grams, (mg) = milligrams, (ug) = micrograms, (IU) = international units

Sources: U.S. Department of Agriculture National Nutrient Database https://data.nal.usda.gov/dataset/usda-national-nutrient-database-standard-reference-legacy-release (Haytowitz et al. 2019) [2] IWC 1979b; [3] Suzuki 1993; [4] Hansen et al. 1990.

In summary, the many benefits associated with consuming marine seafood products, including whale, are well documented in the scientific literature. Marine mammal food products are rich with many of the same nutrients found in commonly consumed seafood products (fish and shellfish), and, in the case of some minerals and vitamins, marine mammal products provide an even richer source.

3.16.3.2 Environmental Contaminants in Gray Whales

While there is documented evidence of the beneficial effects of the nutrients in marine foods, persistent and potentially toxic chemicals also occur and are documented in the diets of native subsistence populations (Verbrugge and Middaugh 2004; Arnold and Middaugh 2004; Chukmasov et al. 2019). In considering the type and amount of chemicals the Makah could ingest by consuming whale products, their continuing exposure to these contaminants is also a result of their ongoing, high consumption of other seafood products, including finfish and shellfish. Numerous researchers have documented concentrations of organic and inorganic contaminants in the tissues (blubber, muscle, organs, etc.) of the gray whales proposed for hunting by the Makah (Varanasi et al. 1994; Jarman et al. 1996; Krahn et al. 2001; Mendez et al. 2002; Ruelas-Inzunza and Paez-Osuna 2002; Tilbury et al. 2002; Ruelas-Inzunza et al. 2003; Dehn et al. 2006a; Dehn et al. 2006b; Dudarev et al. 2019; Hayes et al. 2022).

Whale habitat and migration patterns should be considered when evaluating contaminant concentrations because these factors may affect the magnitude of contaminant concentrations (Houde et al. 2005). The concentration of contaminants in whale tissues will also vary based on the feeding habits of the whale (Houde et al. 2005) and whether the whale is freshly killed or stranded. Gray whales targeted by the Makah filter their food using the bony baleen plates located in their mouths (Vaughn 1978). Typically, this food consists of plankton and other micro- and macrofauna (Vaughn 1978). The levels of contaminants it contains are often lower because of the lesser position of these fauna in the overall marine food chain. Therefore, data on contaminant concentrations in whales that use other feeding strategies, such as toothed whales feeding on larger, older fish that accumulate greater levels of chemicals, are not presented here because they have less relevance to the types of whale (or associated contaminant levels) that are hunted by the Makah (i.e., gray whales). Distinctions are made between contaminant levels in freshly harvested versus stranded whales, because they are often lower in freshly harvested whales than in stranded whales (Rugh et al. 1999; Krahn et al. 2001).

As previously discussed, the Makah Tribe historically consumed large quantities of whale meat and blubber and, to a lesser extent, other portions of the whale (Renker 2018). In the past decade, the

Makah have consumed much smaller quantities of whale products (i.e., on a total biomass basis) compared with historical times. The animals consumed include both stranded as well as one freshly harvested animal following the 1999 hunt (Subsection 3.16.3.1, Nutritional and Health Benefits from Consuming Whale Food Products and Other Traditional Subsistence Foods).

The remainder of this section focuses on describing chemical concentrations measured in whale meat (muscle) and blubber because these are the parts of the whale that are most often consumed. Renker (2018) estimated that harvesting an average of five gray whales per year could yield 24 to 40 pounds (11 to 18 kg) of meat and blubber per Makah. A summary of contaminant concentrations in gray whale blubber and muscle tissue is presented in Table 3-47. Organic compounds (e.g., PCBs, pesticides, and dioxins) are associated predominantly with whale blubber because these compounds are lipophilic (i.e., easily dissolved in lipids or fat). Mean blubber concentrations of chlordanes, DDTs, dieldrin, hexachlorobenzene, mirex, and PCBs in gray whales collected during subsistence hunts (Russian) in the Bering Sea in 1994 (Krahn et al. 2001) (Table 3-47) were 150, 150, 77, 230, 1.6, and 630 micrograms per kilogram (µg/kg) wet weight, respectively. These concentrations tended to be two to three times lower than those measured in stranded gray whales collected over the 1990s in Washington (Table 3-47), indicating that contaminant concentrations may be higher in diseased or aged whales, or in animals in poor nutritional health, that may strand in the Puget Sound region (Table 3-47). Ylitalo (2008) found that elevated concentrations of organochlorine contaminants in the tissues of stranded juvenile gray whales were most likely a result of retention of these chemicals in blubber of the stranded animals as lipid stores were depleted for energy use rather than from a difference in diet or feeding areas. Concentrations of PCBs (1,200 µg/kg wet weight) and DDTs (520 µg/kg wet weight) in blubber of the whale harvested by the Makah Tribe in 1999 were, however, higher than the mean levels reported in stranded gray whales or in those hunted in the Bering Sea (Ylitalo et al. 1999). More recent biopsy samples were collected from gray whales in Mexican breeding lagoons and along the coast of California from 2003-2017 and Hayes et al. (2022) reported mean contaminant concentrations comparable to or lower than levels previously reported (Varanasi et al. 1994, Ylitalo et al. 1999, Krahn et al. 2001, Tilbury et al. 2002). For example, the mean concentrations of ΣPCBs measured in the 2003-2017 biopsied whales (190 µg/kg wet weight) was comparable to or lower than the levels in blubber of most other gray whale groups (Table 3-47). The study was also the first to document and quantify PBDEs and select hexachlorocyclohexanes (HCHs) in gray whales (see Table 3-47).

Concentrations of persistent organic pollutants (POPs) in whale blubber typically were higher or comparable to those in other tissues (e.g., muscle, liver, kidney, or brain) (Krahn et al. 2001). Concentrations of DDTs, hexachlorobenzene, and PCBs measured in biopsy blubber samples using a dart collection method on live whales from Washington State, California State, and Mexico waters tended to be lower than those measured from subsistence or stranded samples (Table 3-47). Jarman et al. (1996) found mostly non-detected concentrations (less than 0.002 µg/kg wet weight) of dioxins in two gray whales that stranded off of California. The concentrations of certain classes of POPs in gray whales typically are lower than in other whale species (Varanasi et al. 1994; Jarman et al. 1996; Krahn et al. 2001; Tilbury et al. 2002; Fossi et al. 2012). However, concentrations for some of these contaminants in whale blubber can be quite high, resulting in quite low "allowable consumption rates." For example, the unweighted average PCB concentration for the 13 sets of gray whale blubber samples in Table 3-47 is 386 µg/kg. While the Washington State Department of Health has not developed screening levels for gray whale blubber[83], this value - combined with the estimated per capita blubber consumption rates in the Tribe's needs statement (approximately 20-25 grams/day; Renker 2018 and other values applied by the Washington Department of Health (e.g., an 8-oz [227-gram] meal size) - yields a calculated "allowable consumption rate" of 0.49 meals of blubber per month. This level would likely result in a 'no consumption' recommendation by the Washington State Department of Health (rounded to 0 meals per month). One of the lower PCB concentrations observed in gray whale blubber (87 µg/kg) would yield an allowable consumption rate of 2 meals of blubber per month and a recommended maximum of two 8-oz (227 gram) meals per month (E. Christie, Washington State Department of Health, pers. comm., March 22, 2023)[84]. While the number of blubber samples is not large and it is possible that PCB concentrations may vary by the area/depth of blubber sampled on each animal, these are the best data available for our analysis.

[83] A screening level is defined by the Washington State Department of Health (2012b) as the concentration of a particular chemical that is of potential public health concern; it is a threshold value against which tissue residue levels of the contaminant can be compared. In determining screening levels for fish flesh, the Washington State Department of Health uses a "general screening level" which reflects the risks borne by the general population as a result of consuming contaminated fish, and a "subsistence screening level" which accounts for the greater risk (i.e., relatively higher body burdens of bioaccumulative contaminants) incurred by subsistence fishers that rely on noncommercial caught fish and shellfish as a major source of protein in their diets.

[84] Allowable consumption rates are simplified by rounding the calculated value to the whole number closest to 0, 1, 2, 4, or 8 meals per month. These conclusions are based on calculations using non-cancer endpoints; calculations based on cancer endpoints would be more restrictive and yield lower recommended consumption rates. The Washington State Department of Health's current practice is to develop health advisories for fish flesh based on non-cancer endpoints.

Few measurements of metal concentrations are available for blubber or muscle of gray whales, and those available are from stranded whales (Mendez et al. 2002; Ruelas-Inzunza and Paez-Osuna 2002; Rueles-Inzunza et al. 2003) or landed whales (Litkova at al. 2020). Metal concentrations typically are higher in muscle tissue compared to whale blubber (Table 3-48). Mean concentrations (in µg/kg dry weight) of metals in muscle tissue from various studies range from 0.4 to 0.86 cadmium, 3.1 to 4.1 copper, 305 to 1,009 iron, 0.6 to 1.11 lead, 0.33 to 0.8 manganese, 0.145 mercury, 1.39 nickel, and 120 to 279 zinc. Methyl mercury composed approximately 75 percent of the total mercury measured in gray whale muscle (Ruelas-Inzunza et al. 2003). Metal concentrations typically were higher in liver and kidney tissues than in muscle or blubber tissues (Mendez et al. 2002; Ruelas-Inzunza and Paez-Osuna 2002; Ruelas-Inzunza et al. 2003; Litkova et al. 2020). Metal concentrations were not reported for the whale the Makah Tribe harvested in 1999.

Since 1998, Chukotka Natives have been reporting a number of hunted whales from the Bering Sea that exhibit a strong medicinal odor, referred to as the 'stinky whale' phenomenon (IWC 2007b). From 2001 through 2017, a total of 37 stinky whales were reported by Chukotka Natives. The average annual catch by Chukotka Natives during that period was 124 animals per year (IWC 2023b). Tissues from these whales have been deemed inedible by hunters. In some cases, people who have tasted the blubber or meat have reported symptoms of numbness of the oral cavity, skin rashes, or stomach aches. Toxicologists have recommended that such whales be considered unfit for human consumption (Ilyashenko 2008).

No known cause has been found, but research is ongoing to determine whether the smells are caused by chemical contaminants, disease, or other factors. Analyses of tissue samples from whales taken in Russian aboriginal hunts found that the concentrations of organochlorines, polyaromatic hydrocarbons, trace elements, and stable isotopes in the tissue of stinky whales fell within the ranges of the concentrations of those substances in non-stinky whales (Rowles and Ilyashenko 2008). In contrast, the concentrations of ketones, aldehydes, and some alcohols in tissue samples from stinky whales were higher compared to samples from non-stinky whales. Some of the compounds may have been lost or changed in concentration because of the repeated freezing and thawing of the samples prior to analysis or other aspects of sample handling (Rowles and Ilyashenko 2008). Another study of necropsied gray whales landed by Chukotka Natives from 2008-2019 reported that lead and cadmium levels exceeded "maximum permissible levels" in the liver and kidneys of stinky whales (Litkova et al. 2020). In a study of gray whales in their winter range, Gulland et al. (2008) found elevated levels of ketones, aldehydes, and alkenes in breath samples collected from adult females with calves. Those results were interpreted as indicating

malnourishment in the animals sampled. Using the preliminary tissue sample analysis results and assuming that the detected compounds are responsible for the stinky condition noted in living whales, scientists developed two hypotheses to potentially explain the presence of high concentrations of various compounds in stinky whale tissues. One possible explanation is that the odor is related to diet. For example, all stinky whales that have been landed had seaweed in their stomachs. This may indicate a mechanism mediated through the digestion of seaweed or other organisms attached to the seaweed (Ilyashenko 2008). It has also been observed that some stinky whales had recently consumed arctic cod, which is unusual for gray whales. Notably, these items have not been observed in the stomachs of non-stinky whales or in stranded gray whales along the U.S. coast (Rowles and Ilyashenko 2008). An alternative explanation is that certain bacteria, fungi, and/or biotoxins may contribute to elevated levels of odiferous compounds found in these whales (Ilyashenko 2008). Based on their analysis of tissues gathered from 2005 through 2011, Polyakova et al. (2012) suggested that the most likely source of the odor was petroleum hydrocarbon contaminants in waters used by gray whales. Using new techniques of solid phase microextraction with headspace gas chromatography- mass spectrometry, Polyakova et al. (2023) concluded that levels of naturally occurring bromophenols were the principal compound responsible for stinky whales. While asserting that the mystery was solved, they noted that questions about the levels of bromophenols in polychaete prey, environmental factors, and potential physiological differences in stinky whales remain (Polyakova et al. 2023).

3.16.3.3 Exposure to Food-Borne Pathogens

Millions of cases of food-borne illness occur each year in the United States, and causes include consumption of subsistence products (Himelbloom 1998; Fagan et al. 2011). Humans can be exposed to several types of pathogenic bacteria (e.g., *Clostridium botulinum*) during the harvesting, processing, preparation, and consumption of marine foods (e.g., fish, shellfish, or whale meat). A review of gray whale health identified a variety of infectious diseases, bacteria, fungi, protozoa, and parasites found in gray whale tissues, some of which present risks for human health (Stimmelmayr and Gulland 2020). There are reports of food-borne illness in Alaska Native subsistence communities where residents frequently consume whale meat and blubber (e.g., cases of botulism and salmonellosis in Alaska Natives consuming hunted or drift whales) (Bender et al. 1972; Shaffer et al. 1990; McLaughlin et al. 2004; Sobel et al. 2004; Fagan et al. 2011). Fagan et al. (2011) reported that the incidence of food-borne botulism in Alaska was greater than 800 times the overall U.S. rate and that nearly 14 percent of 141 food-borne botulism outbreaks in Alaska during 1947 to 2007 were associated with whale fluke, skin, or blubber. They also cited evidence that increasing botulism incidence among Alaska Natives during the 1970s and 1980s was associated with a change from traditional preservation of uncooked aquatic game foods in cool earthen pits to above-ground storage in synthetic containers. From 1990 to 2000, Sobel et al. (2004) reported on 58 botulism events that occurred in Alaska, with 103 persons affected. In 49 of these events, the contaminated food was identified as homemade Alaska Native foods consisting of fermented aquatic animal tissues, including whale skin or blubber (Sobel et al. 2004). Other potential foodborne pathogens related to parasites and bacteria include *Trichinella spp., Toxoplasma gondii, Salmonella and Leptospira spp.* (Tryland et al. 2014). The most common forms of food-borne pathogens identified when subsistence populations consume improperly cooked or handled food products (not just gray whale products) are characterized in Table 3-49. Like other subsistence cultures, the harvesting and consumption of ill-prepared or improperly stored gray whale products represent a potential pathway for exposure of the Makah Tribe to food-borne pathogens.

During butchering and subsequent handling, zoonotic infections can be passed from whale to human. Seal finger, or “Spekk finger,” is an infection passed through cuts and scratches from exposure to whale and seal tissues (Cawthorn 1997). Seal finger attacks the lymph system near the exposure site and nearest finger joints resulting in painful, thickened contracted joints (State of Alaska Epidemiology 1983). Other infections that have been reported from handling marine mammals include tuberculosis, leptospirosis, and brucellosis (Marine Mammal Commission et al. 2009).

Table 3-49. Characteristics of food-borne pathogens[1].

Pathogen	Source	Preferred Environment	Symptoms
Clostridium botulinum	Soil and aquatic environments	Temperature range: 38 to 122 °F (3.3 to 50 °C) pH range 4.6 to 9.0 Salt tolerance: 5 to 10 percent Oxygen: Strict anaerobe[2]	Symptoms are double vision, paralysis, dizziness, difficulty swallowing, speaking, and breathing. Symptoms occur 12 to 72 hours after ingestion.
Enteropathogenic bacteria (Salmonella, Shigella, Escherichia coli, Yersinia, and Campylobacter)	Human and animal intestines, feces	Temperature range: 41 to 117 °F (5 to 47 °C) pH range: 4.5 to 9.0 Salt tolerance: 1 to 3 percent Oxygen: Facultative anaerobe[3]	Symptoms are diarrhea, abdominal pain, fever, nausea, dehydration, urinary tract infection, kidney failure. Symptoms occur 6 to 48 hours after ingestion.
Listeria monocytogenes	Humans, animals, vegetation	Temperature range: 36 to 111 °F (2.5 to 44 °C) pH range: 5.0 to 9.5 Salt tolerance: 10 to 30 percent Oxygen: Facultative anaerobe	Symptoms are flu-like, diarrhea, mild fever, stillbirth or spontaneous abortion. Symptoms occur 1 day to weeks after ingestion.
Staphylococcus aureus	Humans and animals	Temperature range: 50 to 113 °F (10 to 45 °C) pH range: 4.5 to 9.3 Salt tolerance: 10 to 20 percent Oxygen: Facultative anaerobe	Symptoms are vomiting, diarrhea, no fever. Symptoms occur 1 to 8 hours after ingestion.

[1] The food-borne pathogens in Table 3-49 are provided for general information and do not imply that gray whale products contain all of these pathogenic organisms.

[2] Strict anaerobes are bacteria that grow under anaerobic conditions (without oxygen), use anaerobic respiration, and are poisoned by oxygen.

[3] Facultative anaerobes are bacteria capable of growing under either aerobic (with oxygen) or anaerobic conditions.

Source: Himelbloom (1998).

The Makah Tribe hunted and harvested a gray whale in 1999. In the following account, Renker (2018) describes the processing of the whale caught in 1999. The account illustrates some potential health-related issues.

> . . . Some 1,400 Makahs welcomed the whale to Front Beach in Neah Bay, and paid honor to the great creature. Many Makahs ate raw blubber right on the spot, and then began the task of preparing the food and resources that the whale contributed to the Makah people.
>
> Butchering the whale proved a huge task for the Makah people. Lack of familiarity with gray whale anatomy, tools poorly adapted for gray whale meat and blubber, and logistical issues presented immediate obstacles for the butchering process which began on Front Beach. Some confusion also centered on whale parts other than meat and blubber. Most

importantly, Makah were able to overcome these problems and continue with the job of processing the whale.

In a matter of hours, a flatbed truck had taken what was left of the whale and driven to the Makah Tribe's fish plant, a processing plant with 800 cubic feet (22.7 cubic m) of freezer space and a service entrance large enough to allow the flatbed to drive inside. Within 24 hours, Front Beach showed no sign of the momentous event which had happened the previous day. The Makah butchering crew, which included Makahs who had traveled to Alaska to learn the processing techniques, had some assistance from an Alaska Native. Many people worked to butcher the parts of the whale which had not been distributed to Tribal members on the night of 17 May. In addition to meat and blubber, Makahs interviewed during the Makah Household Survey reported requesting and receiving whale lice, sinew, baleen, brain, and heart. Other Makahs reported that they would have liked to receive liver, cheeks, eyes, and intestines. Some of these items, like whale lice and baleen, are primarily used for ceremonial reasons, while others can be used in tool production or as food. The bulk of the food products derived from the whale were reserved for the Tribe's celebratory feast, which was to be held on 22 May.

In private homes, people welcomed whale meat, blubber, and other whale parts. Between 17 May and 22 May, some households began to use recipes held in family confidence for decades, and others experimented with techniques used for other sea creatures, like seals and fish.

In summary, pathogenic organisms can and do occur in marine mammals and associated food products, including seals, walrus, dolphins, and whales. Illness has been reported in those who eat or handle these animals and food products, though they typically come from consuming either stranded or drift animals, or they result from improper preparation of traditional food products.

3.17 National and International Regulatory Environment

3.17.1 Introduction

The following sections describe national conditions related to the harvest of marine mammals and international conditions related to the harvest of whales.

In the United States, take of marine mammals is prohibited, with certain exceptions and exemptions (Subsection 1.2.3.2 Section 101(a) – Take Moratorium). Harvest of whales is prohibited by WCA regulations, except for ASW authorized by paragraph 13 of the IWC

Schedule (50 CFR 230.2) (Subsection 1.2.4.2, National Whaling Governance Under the WCA). This section reviews past waivers and requests for waiver of the MMPA take prohibition.

Internationally, harvest of whales is regulated by the ICRW (Subsection 1.2.4.1, International Whaling Governance under the ICRW), which established the IWC as the regulatory body governing whaling (Subsection 1.2.4.1.1, Functions and Operating Procedures of the IWC). While the IWC initially focused on regulating commercial harvest, from 1982 to 1986 the body phased in a moratorium on commercial whaling to be in effect pending adoption of a revised management scheme. Since that time, the parties to the ICRW have attempted to adopt a regulatory regime that would govern commercial harvest; these attempts have been unsuccessful and the moratorium remains in effect. The ICRW also governs ASW but does not set limits on lethal research on whales. This section examines the whaling that has occurred worldwide since the IWC moratorium, the debates within the IWC over the different types of whaling, the United States' role in those debates, and the potential relationships between the positions and actions of the United States and whaling worldwide.

3.17.2 Regulatory Overview

3.17.2.1 Marine Mammal Protection Act

The MMPA take moratorium and the process for waiving the moratorium are described in detail in Subsection 1.2.3, Marine Mammal Protection Act. In addition to those provisions, section 109 of the Act pre-empts state authority governing marine mammals but includes provisions for the Secretary to waive the take moratorium and return management authority to a state if certain conditions are met.

3.17.2.2 Whaling Convention Act

The WCA is described in detail in Subsection 1.2.4, Whaling Convention Act.

3.17.2.3 International Convention for the Regulation of Whaling

The ICRW is described in detail in Subsection 1.2.4.1, International Whaling Governance under the ICRW, in particular its provisions regarding commercial and aboriginal subsistence whaling. In addition, Article VIII of the ICRW authorizes parties to grant its nationals a special permit authorizing lethal scientific research, subject to conditions the contracting government thinks fit. Any killing or taking of whales under Article VIII is exempt from the operation of the convention. Article VIII also specifies requirements for reporting on and using (processing and distributing) whales after they are killed for scientific research. While contracting governments must submit scientific research permits to the IWC and its Scientific Committee for review, it is the contracting government that ultimately decides whether to issue a permit.

3.17.2.4 Pelly Amendment

Under the Pelly Amendment (22 USC 1978) to the Fishermen's Protective Act of 1954, when the Secretary of Commerce determines that the nationals of a foreign country are diminishing the effectiveness of an international fishery conservation program (including the IWC's program), the Secretary certifies this fact to the President. The President then has the discretion to ban imports of any products from the offending country "to the extent such prohibition is sanctioned by the World Trade Organization" (22 USC 1978) and/or direct Agencies to take non-trade related actions to encourage the certified nation to change its actions or the actions of its nationals. After making a certification, the Pelly Amendment requires the Secretary of Commerce to periodically review the activities of nationals of the offending country to determine if the reasons for which the certification was made no longer prevail. If so, the Secretary shall terminate the certification. If not, the certification remains active (22 U.S.C 1978 (d)). A "Pelly Certification" has the potential to dissuade foreign governments from particular activities through a public announcement of their certification and the possibility of trade or non-trade sanctions. As of September 15, 2011, the Secretary had made 16 certifications under the Pelly Amendment for whaling activities, including one in 2011 for Iceland's commercial whaling (Office of the U.S. Press Secretary 2011) and one in 2014 for Iceland's whale meat trade, citing diminished effectiveness of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES)[85]. The United States has not imposed trade sanctions as a result of Pelly Amendment certifications for whaling activities.

3.17.2.5 Packwood-Magnuson Amendment

In 1979, Congress passed the Packwood-Magnuson Amendment to the Magnuson Stevens Act of 1976. It requires the Secretary of Commerce to "periodically monitor the activities of foreign nationals that may affect [international fishery conservation programs];" (22 USC 1978(a)(3)(A)) "promptly investigate any activity by foreign nationals that, in the opinion of the Secretary, may be cause for certification," (22 USC1978(a)(3)(B)); and "promptly conclude; and reach a decision with respect to; [that] investigation" (22 USC 1978(a)(3)(C)). If the Secretary of Commerce certifies that "nationals of a foreign country, directly or indirectly, are conducting fishing operations or engaging in trade or taking which diminishes the effectiveness of the International Convention for the Regulation of Whaling" (16 U.S.C. 1821(e)(2)(A)(i)), the Secretary of State

[85] https://obamawhitehouse.archives.gov/the-press-office/2014/04/01/memorandum-pelly-certification-and-icelandic-whaling

must reduce, by at least 50 percent, the offending nation's fishery allocation within the United States' fishery conservation zone (16 USC 1821(e)(2)(B)). Although the Amendment requires the imposition of sanctions when the Secretary of Commerce certifies a nation, it did not alter the initial certification process, except for requiring expedition. It also provided that a certification under the Packwood-Magnuson Amendment also serves as a certification for the purposes of the Pelly Amendment (16 USC 1821(e)(2)(A)(i). The Packwood-Magnuson Amendment is no longer influential because no foreign whaling nation currently fishes in United States waters (Buck 1998).

3.17.3 Existing Conditions

3.17.3.1 Waivers of the MMPA Take Moratorium

There have been few waivers of the MMPA take moratorium since passage of the MMPA (Bean 1997). This section examines past instances in which waiver of the MMPA take moratorium has been considered.

With passage of the MMPA and preemption of state management authority, the State of Alaska sought a return of management authority for 10 marine mammal species under section 109. In 1976, the Secretary of Interior returned management authority for walruses to Alaska (41 FR 14373, April 5, 1976). The Secretaries of Interior and Commerce conditionally approved Alaska's request for the other nine species in 1979 (44 FR 2540 and 2547, January 11, 1979). Alaska Natives challenged the state's ability to regulate their hunts for these species under the returned authority and prevailed in district court (*People of Togiak v. United States* 1979). In response to the court's decision, Alaska returned authority for walruses to the federal government and stated its intention not to pursue management authority over the remaining species (44 FR 45565, August 2, 1979). Congress reacted by revising section 109 to, among other things, allow financial assistance for states to develop management programs, as well as implement them. No state has sought management authority over marine mammals since Alaska's request.

In 1975, a fur importer, the Fouke Company, sought a waiver and permit to allow importation of baby fur seal skins from South Africa. NMFS granted the waiver in 1976 conditioned on harvest of the seals in South Africa not exceeding a certain level for the year. While Fouke's application for a permit was pending, it became known that the harvest level had been exceeded, so no permit was issued. Fouke applied for a permit to import skins from the following year's harvest, which NMFS granted. A federal circuit court ultimately invalidated the waiver and regulations because NMFS' decision did not meet MMPA requirements (the skins were from seals that were less than eight months old and nursing at the time of taking) (*Animal Welfare Institute v. Kreps* 1977).

In 1985, the Safari Club International petitioned the Secretary of Commerce to adopt a rule regarding waiver of the moratorium that would include, among other provisions, a requirement that NMFS review the status of marine mammals every 5 years and whenever a waiver was proposed would make a final determination within 2 years of the proposal. In denying this petition, NMFS stated its belief that "administrative resources can best be utilized if waiver proceedings are initiated only when there is an indication that a waiver may be appropriate or when a specific proposal is under consideration" (51 FR 16085, April 30, 1986).

NMFS waived the moratorium and published regulations governing the take of Dall's porpoise in the Japanese fishery in the Bering Sea and North Pacific in 1987 (52 FR 19,874, May 28, 1987). NMFS did not waive the moratorium and publish regulations, however, for fur seals and other marine mammals that would be taken in the fishery, because of insufficient information. In invalidating NMFS' waiver and regulations, the court stated that NMFS could not authorize a fishery it knew would take marine mammals not covered by the waiver and regulations (*Kokechik Fisherman's Association v. Secretary of Commerce* 1988).

3.17.3.2 Worldwide Whaling

The following discussion describes commercial, scientific, and aboriginal subsistence whaling worldwide within the IWC context, focusing in particular on the United States' position and role in the international debates. Figures 3-16 to 3-18 and Tables 3-50 to 3-52 depict the harvest in commercial, scientific, and aboriginal subsistence whaling conducted under IWC auspices since the commercial whaling moratorium became effective. Commercial whaling declined dramatically then ceased following the moratorium, grew steadily from 1991 through 1997, and has remained fairly level since that time. Scientific whaling increased steadily after 1985, peaked in 2005, and declined significantly in 2010. Aboriginal subsistence whaling has remained fairly steady, fluctuating around 350 whales harvested per year since the mid-1990s. The trend prior to 1998 is confounded by the fact that the hunt by the Chukotka Natives ceased altogether in 1992 and 1993 following the dissolution of the Soviet Union and state support for the hunt.

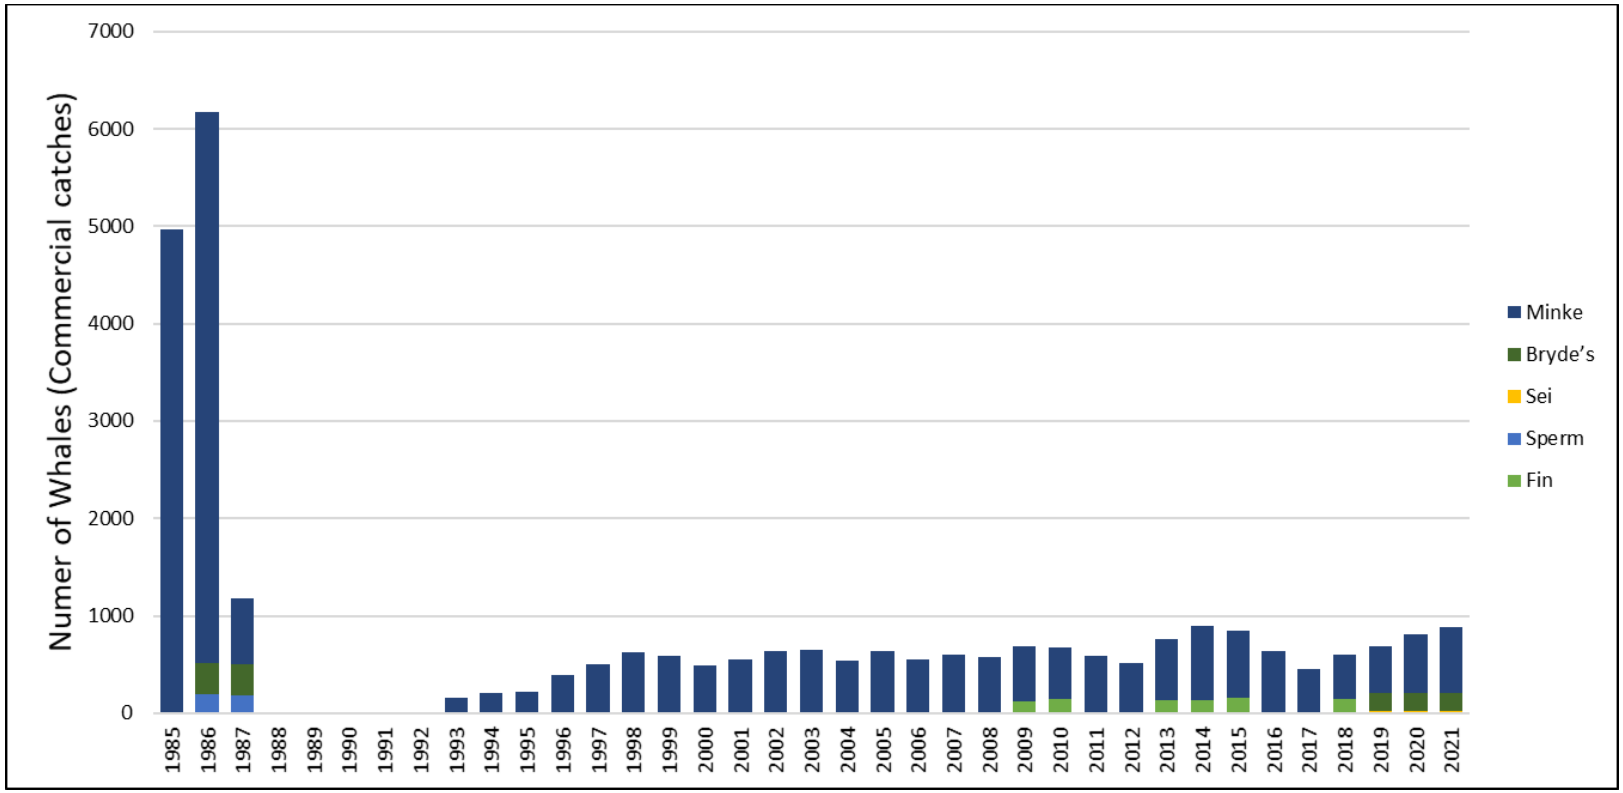

Figure 3-16. Commercial whaling catches by species since 1985 (see also Table 3-50).

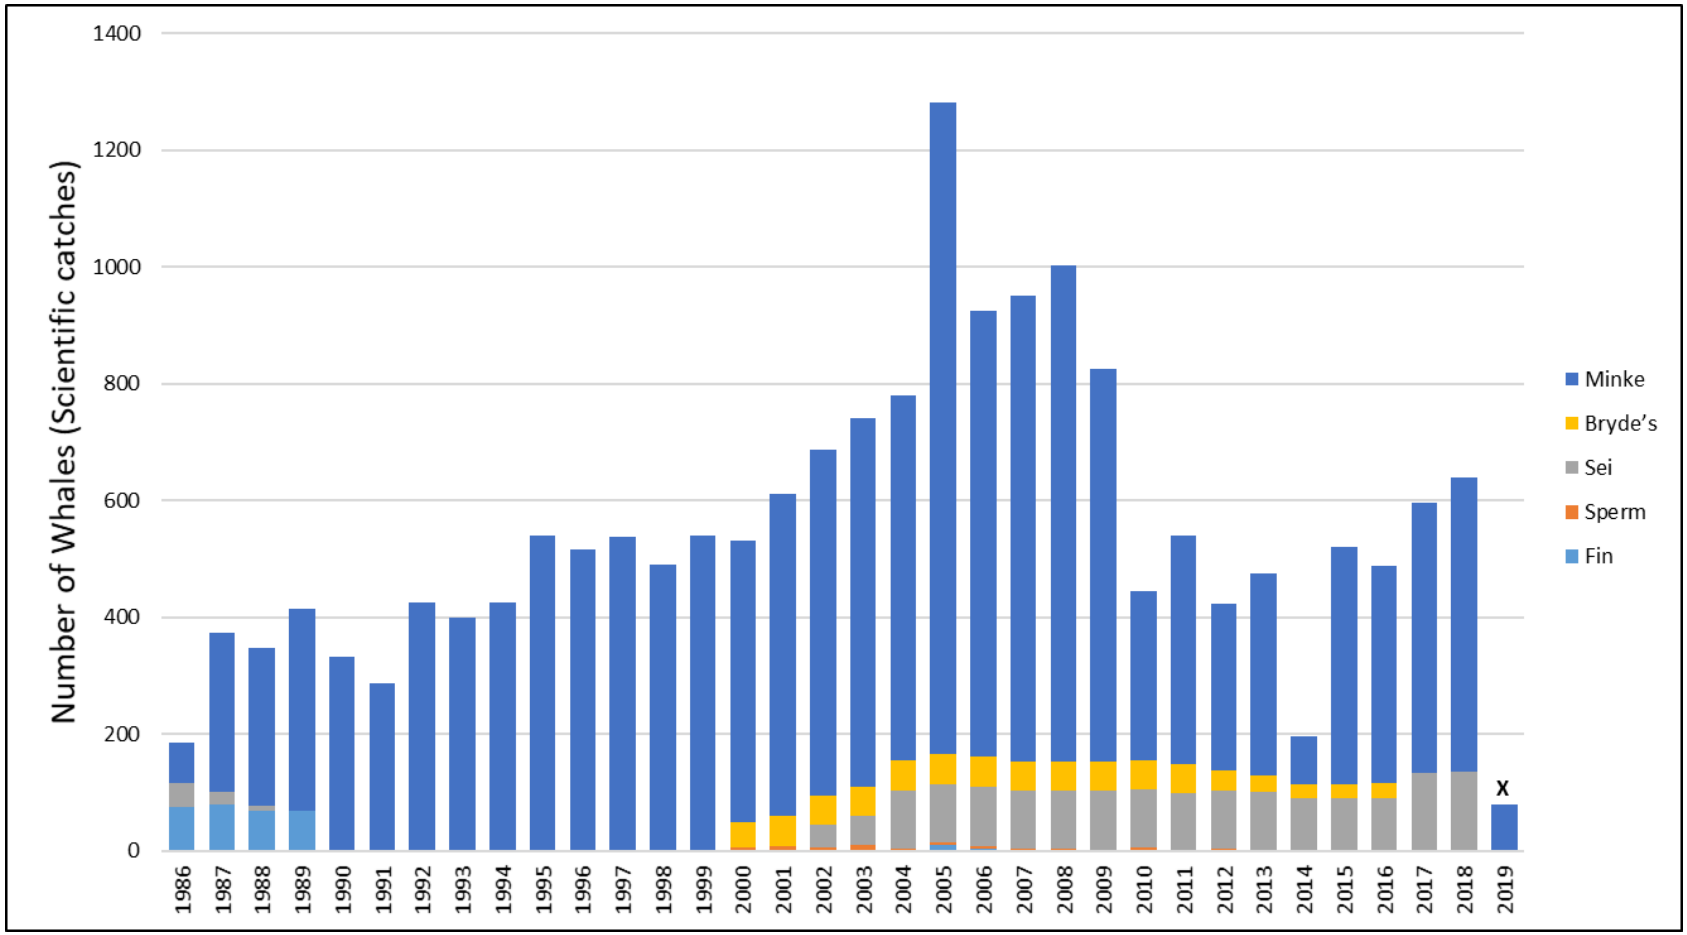

Figure 3-17. Scientific whaling catches by species since 1986 (see also Table 3-51). X indicates data are incomplete for that year.

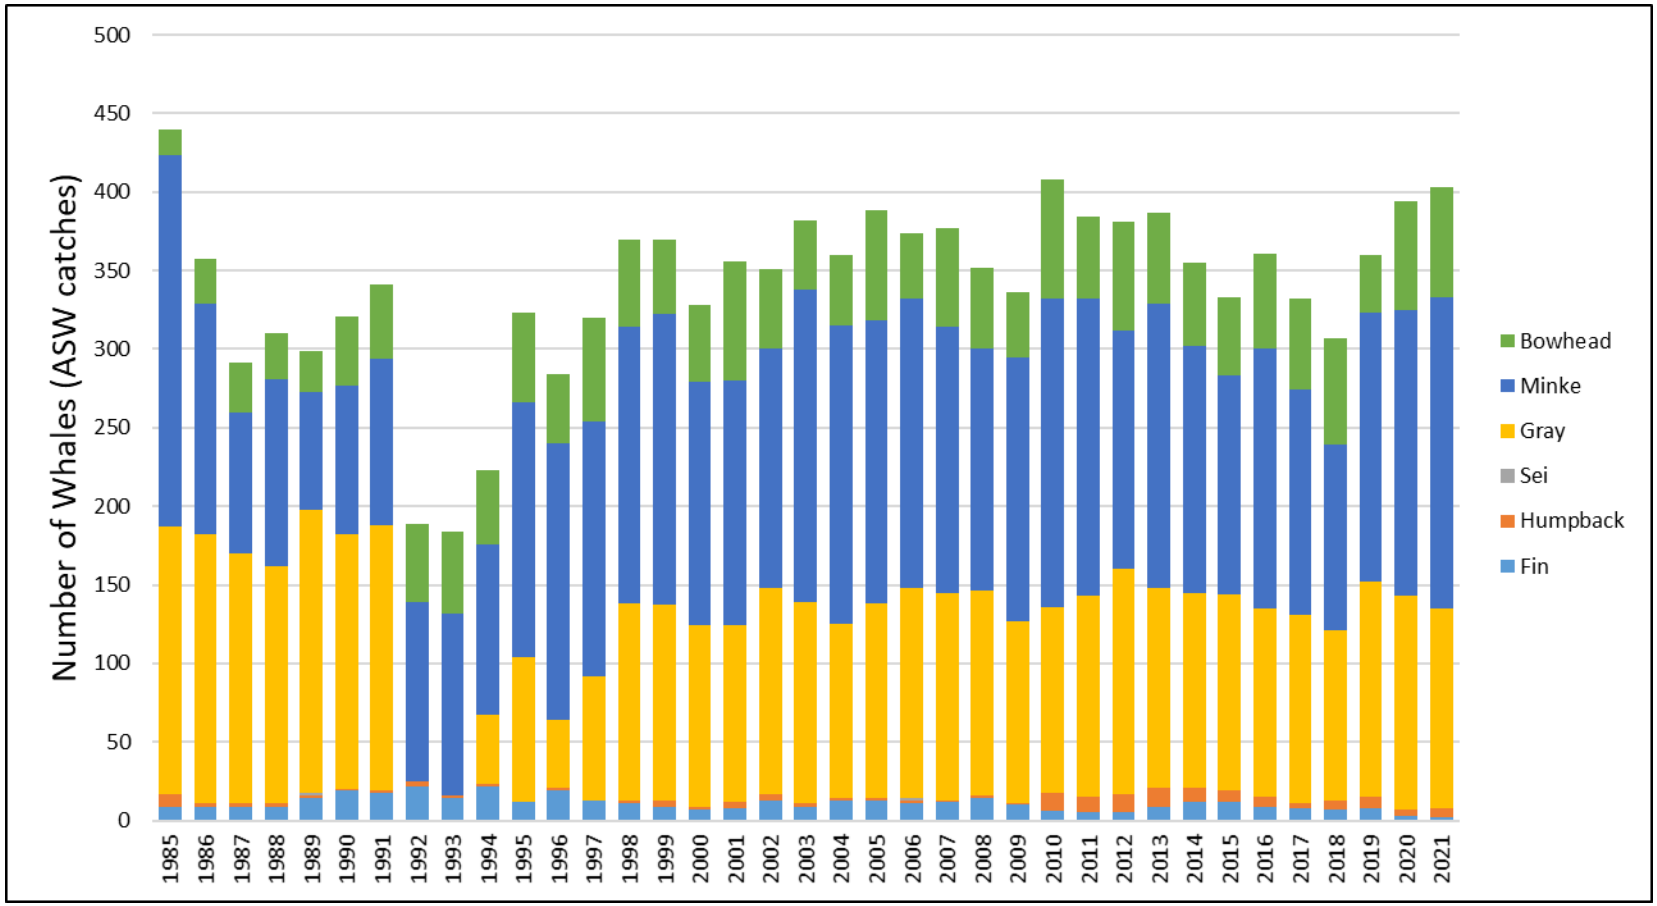

Figure 3-18. Aboriginal subsistence whaling catches by species reported to the IWC since 1985 (see also Table 3-52).

Table 3-50. Commercial whaling catches since 1985 (taken under Objection or Reservation to the Moratorium).

3.17.3.2.1 Commercial and Scientific Whaling

The United States was a leader in establishing the 1982 moratorium on commercial whaling (Stoett 1997). In 1949, the United States passed the WCA, banning all commercial whaling by United States nationals. Congress adopted resolutions requesting the Secretary of State to negotiate a 10-year moratorium on the commercial killing of whales in the international arena (16 USC 916 note, PL 96-60, August 15, 1979, 93 Stat. 403). In 1972, the first United Nations Conference on the Human Environment in Stockholm adopted a resolution calling for such a moratorium. The United States lobbied at each subsequent IWC annual meeting for incorporation of the moratorium into the IWC schedule, until its eventual adoption.

Prior to adoption of the moratorium, the Secretary of Commerce certified a number of countries under the Pelly Amendment finding their whaling activities diminished the effectiveness of the ICRW. In 1974, the Secretary of Commerce issued the first certifications under the Pelly Amendment directed at Japan and the Soviet Union for whaling in excess of IWC quotas. In 1978, the Secretary of Commerce certified Chile, Peru, and the Republic of Korea under the Pelly Amendment for their whaling practices.

In 1982, when the commercial whaling moratorium was adopted, Japan, Peru, Norway, and the Soviet Union all lodged objections. In response to Japan's objection to the moratorium and continued commercial whaling, the United States threatened to end Japanese access to fishing in United States waters under the Packwood-Magnuson Amendment. Japan withdrew its objection to the moratorium by 1988, and Peru withdrew its objection in 1983. The Soviet Union conducted pelagic commercial whaling of minke whales in the southern hemisphere through the 1985/1986 season. The Soviet Union never withdrew its objection, but stopped harvesting whales commercially after 1986. The Russian Federation, successor state to the Soviet Union, has not engaged in commercial whale harvest, but its objection to the moratorium remains.

When Norway objected to the moratorium and conducted small type coastal whaling in the 1986 and 1987 seasons, the Secretary of Commerce certified Norway under the Pelly Amendment; in 1987 Norway suspended its whaling. The Secretary of Commerce also certified Norway in 1990 and 1992 for its research whaling program. Norway then resumed commercial whaling in 1993 and was again certified by the Secretary of Commerce under the Pelly Amendment (Clinton 1993; Ek 1996). President Clinton did not impose trade sanctions, and explained in a letter to Congress that while "[t]he United States is deeply opposed to commercial whaling . . . [there is] an equally strong commitment to science-based international solutions to global conservation problems" (Clinton 1993). Clinton acknowledged that "not every country agrees with our position

against commercial whaling" and initiated preparations for sanctions, but ultimately concluded that "the primary interest of the United States [is in] protecting the integrity of the IWC and its conservation regime," which could best be achieved through diplomatic measures (Clinton 1993). Norway remains certified under the Pelly Amendment. Norway is the only original objecting party that still conducts commercial whaling under objector status. The IWC has passed numerous resolutions asking the government to reconsider its objection and immediately halt all whaling under its jurisdiction (see for example, IWC Resolutions 1995-5, 1996-5, 1997-3, and 2001-5).

The Secretary of Commerce certified Japan's scientific whaling program in 1988, when Japan initiated its Antarctic program to conduct lethal studies of minke whales; in 1995, after Japan extended its minke whale program to the North Pacific; and in 2000 when Japan expanded its scientific whaling operations to include protected Bryde's and sperm whales. The Secretary stated that the U.S. Government was "deeply concerned that the real aim of this large hunt is to pave the way for an outright resumption of commercial whaling (Mineta 2000)."

Iceland did not lodge an objection to the commercial whaling moratorium in 1982 but subsequently disagreed with maintenance of the ban and withdrew from the IWC in 1992. In 2002, Iceland was successful in obtaining re-admission to the IWC but lodged a reservation to the moratorium. The United States, along with 17 other countries, objected to Iceland's reservation to the moratorium when it was re-admitted to the IWC in 1992. The reservation language provides that Iceland would not authorize whaling for commercial purposes before 2006, after which it would not authorize whaling while progress is being made in negotiations on the management of commercial whaling. Iceland announced its intent on October 17, 2006 to resume commercial whaling for minke and fin whales (Black 2006; Fenner 2006). See Table 3-50 for a summary of Icelandic commercial whaling. When Iceland resumed commercial whaling in 2006, the United States joined 24 other countries in lodging formal objections with the government of Iceland. The Secretary of Commerce also certified Iceland under the Pelly Amendment in 2004 and retained the certification in 2006. The Secretary again certified Iceland in 2011 for its harvest of endangered fin whales (Locke 2011). This certification remains in effect, along with the 2014 certification for Iceland's whale meat trade, though no trade sanctions have been imposed.

The continuing controversy over commercial whaling makes the future of whaling, and of the IWC, uncertain. The IWC in 1994 adopted the Revised Management Procedure, which is a method for determining a sustainable catch limit for some whale species. Nevertheless, the IWC did not lift the moratorium on commercial whaling because several parties, including the United

States, argued that an inspection and control scheme was necessary to manage a hunt (Hogarth 2008). This scheme, together with the Revised Management Procedure, is known as the Revised Management Scheme. The consistent position of the United States has been that the moratorium should not be lifted at least until a revised management scheme is in place (Department of State 2003), and the United States has participated in good faith in negotiating such a scheme.

Discussions on the revised management scheme within the IWC remained at an impasse for several years. In 2006, a slight majority of IWC member nations adopted a resolution declaring the commercial whaling moratorium no longer necessary (IWC Resolution 2006-1, 'St Kitts and Nevis Declaration'). Yet at the 2007 IWC meeting in Anchorage, 37 countries adopted a resolution stating that the whaling ban "remains valid" (IWC 2007b). While slight majorities within the IWC have thus succeeded in adopting contradictory resolutions regarding the commercial whaling moratorium (resolutions are nonbinding), definitive action on the commercial moratorium or the revised management scheme is uncertain because neither the pro-commercial-whaling or anti-commercial-whaling sides of the debate have the three-fourths majority necessary for action (Henderson 2005; Hogarth 2006).

This paragraph summarizes the efforts from the 2007 annual meeting through the 2010 annual meeting to move forward on the revised management scheme, as reported in the Chair's Report from the 2010 meeting (IWC 2010c). At its 2007 annual meeting, the IWC agreed to hold a working meeting prior to its 2008 annual meeting to discuss the future of the IWC given the impasse over the revised management scheme. The group met in March 2008 and made sufficient progress that the IWC agreed at its 2008 meeting to establish a small working group to develop a package or packages for consideration by the IWC. At its 2010 annual meeting, the IWC considered the package developed by the small working group, which included a number of components. Those components included suspending the moratorium for 10 years on whaling occurring under special permit, objection, and reservation; bringing all whaling authorized by the parties under control of the IWC; limiting whaling to members currently whaling; ensuring no new non-indigenous whaling takes place on whale species not currently hunted; establishing caps for 10 years significantly lower than the current catches; introducing IWC monitoring, control, and surveillance for non-indigenous whaling; and creating a South Atlantic whale sanctuary. At the end of discussions on the proposal, the IWC chair concluded that consensus was not possible and provided personal guidance that the parties should proceed to work on important issues where there was no agreement, and to avoid discussion of contentious matters in IWC plenary sessions.

The IWC did not discuss the revised management scheme during its 2011 and 2012 annual meetings, and at the 2012 meeting the IWC decided to switch to biennial meetings (IWC 2012b).

At the 2022 biennial commission meeting, Antigua and Barbuda presented a proposal for a "Resolution on the Implementation of a Conservation and Management Program for Whale Stocks aimed towards the lifting of the moratorium and the orderly development of the whaling industry," noting that the IWC has a strong whale conservation focus and that the Commission has not been fulfilling its responsibilities to manage whaling (IWC 2022c). Several countries expressed support for the resolution, citing food security concerns and recovery of certain stocks. Others opposed the resolution, citing existing environmental and anthropogenic threats to cetaceans and an apparent lack of interest from any contracting government in investing in new infrastructure and compliance frameworks for commercial whaling. While a decision on the resolution was not made at the meeting, it was agreed that work will continue intersessionally. The proposal will be submitted for the next meeting in 2024.

3.17.3.2.2 Aboriginal Subsistence Whaling

Although aboriginal subsistence whaling was not controversial in the IWC through the mid-1970s, since that time several issues have arisen. One debate has focused on the sustainability of aboriginal subsistence harvests. Examples of harvests that have generated controversy include harvest of bowheads by Alaska Natives and harvest of minke, humpback, and fin whales by Native Greenlanders. Bowheads are listed as endangered under the ESA and listed in Appendix I of CITES (Subsection 1.4.1.2.1, Relevant Overview of Requests for Bowhead Whales on Behalf of Alaska Natives). In the early 1970s, the IWC Scientific Committee expressed concern about the status of the bowhead whale stock, and at the 1977 annual meeting of the IWC, recommended that the catch limit for aboriginal subsistence harvest of bowheads be set at zero (accepted by the IWC with a vote of 16-0, with the United States abstaining). In a subsequent special meeting in 1977, the United States and the Alaska Eskimo Whaling Commission presented a request to modify the ban and allow for a take of bowhead by Alaska Natives. Although the Scientific Committee rejected the proposal, the IWC plenary session allowed for a limited and strictly controlled hunt for 1978. Work on the bowhead aboriginal subsistence hunts continued in workshops and working groups following the special meeting. Some argued that the United States, by supporting an aboriginal hunt contrary to scientific advice regarding the conservation status of the stock, undermined the conservation arguments the United States and the IWC used to maintain the commercial moratorium (Hankins 1990). Continuous research since then has addressed questions regarding sustainability of a bowhead harvest.

Native Greenlanders harvest North Atlantic minke, humpback, and fin whales, which are classified as protected stocks under the IWC Schedule. For a number of years, the IWC Scientific Committee was unable to provide scientific advice to the IWC on safe catch limits because of lack of information regarding stock structure and minimum stock level, although this changed in 2007 with more solid data and advice on sustainable catch limits (IWC 2007b). The Scientific Committee continues to be able to provide advice on the sustainable catch of these stocks based on solid data.

Debate in the IWC over ASW also centers on what groups of people qualify as aboriginal subsistence whalers, what manner of hunting qualifies as aboriginal subsistence hunting, and what use of the products of the hunt qualifies as subsistence use. Criticisms come from those who support commercial whaling and argue for equal consideration and from animal rights groups opposed to all forms of whaling or concerned that aboriginal hunting methods result in inhumane killing. Criticisms have been leveled at the Greenlander, Bequian, Chukotkan, Alaska Native, and Makah hunts based on arguments that the hunters are not aborigines, that the manner of hunting is not aboriginal, or that the use of the products is not subsistence use.

Some critics have noted that the hunts of Greenlanders are particularly difficult to distinguish from commercial whaling because of the close integration of hunting and fishing activities and waged employment (Reeves 2002; Stevenson et al. 1997), plus the sale of 'mattak' and other surplus whale products on the Greenland market (Reeves 2002; Heide-Jørgensen 1994; Johansen 1997; High North Alliance 2007). At the 2012 meeting of the IWC, there was considerable discussion regarding Greenland's needs statement (including topics related to harvest conversion factors, the availability of whale meat in restaurants, human health, and political practicalities), and the Commission did not adopt a proposed Schedule amendment for 6-year catch limits for the Greenland hunts (IWC 2012c).

The Bequian harvest is an offshoot of New England-based whale fisheries that operated in the West Indies in the mid-1700s (Reeves 2002). Meat from humpbacks is still considered highly palatable by the Afro-Caribbean population of St. Vincent and the Grenadines, and meat for local consumption seems to be the principal incentive for whaling, although products from the hunts (especially oil) are also sold on the wider regional market (Caldwell and Caldwell 1975; Australian National Task Force on Whaling 1997; Reeves 2002). The Bequian harvest of humpback whales was limited to a few whales by primarily one person for several years and was originally intended to be phased out. At the IWC annual meeting in 1996, however, St. Vincent

and the Grenadines reported that a new whaler had taken up humpback whaling, causing concern on the part of some delegates (IWC 1997).

The Chukotkan hunt has raised concerns about the use of products from the hunt, because the blubber and some other gray whale components were being used as food in fox fur farms (IWC 1996; Australian National Task Force on Whaling 1997).

The 'subsistence use' definition formally adopted by the IWC includes the barter, trade, or sharing of whale products primarily within the local community and allows for the sale of handicrafts made from whale products. Commercial whaling proponents argue that this creates a double standard and that sharing, bartering, and trading meat amounts to commerce (Stoett 1997). Alaska Natives are allowed to sell native articles of handicraft from bowhead whales within the borders of the United States under the provisions of the MMPA, and the restrictions were similar for the 1998 through 2000 Makah hunts, as well as under the Tribe's Proposed Action (Alternative 2) and the Preferred Alternative (Alternative 7). In the past, questions have been raised about whether the Makah harvest was a subsistence harvest because their original 1995 formal request to resume hunting of ENP gray whales stated that the Makah were reserving what they consider their treaty-secured right to whale for commercial purposes. They classified their ceremonial and subsistence request as 'interim.' The present request does not include such a statement.

The legitimacy of the Makah request has also been questioned because of the Tribe's 70- to 80-year hiatus in whaling. (Subsection 1.1.4, Summary of Makah Tribe's Historic Whaling Tradition, and Subsection 3.10.3.4.2, Factors Responsible for Discontinuation of the Hunt, describe the reasons for the hiatus.) The 1981 Ad Hoc Technical Working Group's working definition of 'aboriginal subsistence whaling' refers to a "continuing traditional dependence" on whale products for subsistence (Section 3.17, Regulatory Overview; Subsection 1.4.1.2.1, Relevant Overview of Requests for Bowhead Whales on Behalf of Alaska Natives; Subsection 1.4.1.2.2, Overview of Requests for ENP Gray Whales on Behalf of the Makah). While other aboriginal subsistence whalers have had smaller breaks in subsistence tradition (e.g., the Chukotkans stopped whaling for a few years in the 1990s), no other group has had a break lasting for more than a generation.

Additional controversy was generated over the legitimacy of the Makah hunt as an aboriginal subsistence hunt when the IWC adopted Schedule language stating that products from the hunt "were to be used exclusively for local consumption by the aborigines whose traditional aboriginal subsistence and cultural needs have been recognized" (IWC 1997) (Subsection 1.4.1.2.2,

Overview of Requests for ENP Gray Whales on Behalf of the Makah). Some observers asserted that "the more flexible the aboriginal subsistence whaling definitions become, the more susceptible the IWC will be to unyielding pressure by other communities with traditions of harvesting and using whales for commercial purposes" (Jenkins and Romanzo 1998). This issue became moot when the words "whose traditional aboriginal subsistence and cultural needs have been recognized" were deleted from Schedule 13 (Subsection 1.4.1.2.2, Overview of Requests for ENP Gray Whales on Behalf of the Makah).

Beginning in 1986, Japan argued that its coastal villages (generally referred to as small type coastal whaling) should be allowed to whale under the ASW exception, also requesting that the sale of meat from the hunt be allowed on the open market. At the IWC meeting in 2002, Japan and other pro-whaling parties withheld support for the United States' request for a bowhead quota for the years 2003 through 2007, but did not oppose the joint request of the Russian Federation and the United States for gray whales. Later that year at a special meeting, Japan and others approved catch limits for bowheads through 2007, and the United States voted in favor of a resolution regarding Japan's plan for small type coastal whaling if it was non-commercial and based on scientific advice. That resolution did not pass.

At the 2007 IWC meeting in Anchorage, Japan continued to press for an allowance for small type coastal whaling. In a statement to the press, Japan's Commissioner argued that small type coastal whaling is no different from ASW and accused IWC members of imposing a "double standard" (Hopfinger 2007). Prior to the meeting, the Japanese Commissioner stated that Japan would not oppose the Alaska Native quota, while the United States Commissioner was quoted in the Anchorage papers saying the United States would strike no deals with Japan even if Japan opposed the bowhead quota (deMarban 2007). The United States' request for updated bowhead catch limits and the joint request of the Russian Federation and United States for gray whale catch limits were approved by consensus. Japan has continued to reserve its right to propose an amendment to the schedule to allow small type coastal whaling (see, for example, IWC 2012b) but has not yet done so.

Outside the IWC forum or any international regulatory regime, aboriginal subsistence hunting occurred for hundreds to thousands of years. Refer to Subsection 3.4.3.6.1, Aboriginal Subsistence Whaling, for a list of tribes engaged in historic aboriginal hunts of ENP gray whales from California to Alaska and Chukotka. More recently, aboriginal subsistence hunts of whales is known to continue, or to have continued until recently, in three tropical areas: 1) humpback whale hunts in Equatorial Guinea, 2) sperm whale and other species in Indonesia, and 3) Bryde's

whales in the Philippines. The humpback whale hunt off the island of Pagalu in the Gulf of Guinea is thought to have been introduced by American ship-based whalers in the 18th and 19th centuries (Reeves 2002). Natives target humpback calves, with an estimated catch level of 3 or fewer humpbacks per year (Aguilar 1985; Reeves 2002). Whale hunts for sperm whales and other whales off two Indonesian islands predates the arrival of American and English whalers by at least two centuries (Barnes 1991; Barnes 1996). Fishing, including whaling, is the principal source of sustenance, and whale products, including meat and oil, are sold at local markets (Barnes 1991; Barnes 1996; Reeves 2002). One group of natives has mainly targeted sperm whales in the large whale catch in recent years, totaling a catch of 664 whales from 1959 to 1995, while another group of natives seems to target mostly baleen whales, including fin, sei, and minke whales (Barnes 1996; Reeves 2002). Both groups also hunt small cetaceans. Bryde's whales were the main targeted species in the Philippines until the last documented catch in 1996, when a Philippine administrative order expanded the prohibition on killing dolphins to include all cetaceans (Reeves 2002). Whale hunting origins among fishermen ranged from 100 years to opportunistic hunting in the last few generations.

Although the United States has consistently supported sustainable ASW, it objected to Canada's authorization of a bowhead hunt by Inuit hunters. In 1996, the Commerce Secretary certified Canada under the Pelly Amendment for allowing Inuit hunters to take two bowhead whales. The Secretary's certification stated that "[t]he United States supports aboriginal whaling when it is managed through the International Whaling Commission, the global body charged with responsibility for the international conservation and management of whale stocks and the regulation of whaling" (NOAA 1996). Canada withdrew from the IWC in 1982.

In 2018, the IWC adopted several new provisions in the ASW quota allocation process through amendments to the IWC Schedule (IWC 2018b). These provisions aimed to ease the considerable burden placed on ASW countries in obtaining and renewing their quotas, and provide some stability and security for the indigenous subsistence hunters they represent. The first provision deals with the timing of the quota renewal process. The one-time 7-year quota block beginning in 2019 shifted the expiration of the quotas to one year after the Commission meeting, during which they would be considered for renewal. This allows for a buffer year after the Commission meeting so that an ASW country could revise or re-submit a quota request in the event that the original request was not endorsed at the regular Commission meeting. Therefore, the current catch limits will be reviewed in 2024, but they will not expire until 2025. Beginning in 2026, the quota period will return to a 6-year block to maintain this timeline (IWC 2018d).

The IWC also adopted a carryover provision for unused strikes in a quota block. This provision allows for greater flexibility for subsistence hunters to use their strikes when it is safe for them to do so. The carryover provision does not change the total number of strikes allowed within a quota period; however, it does affect when those strikes may be used (IWC 2018d). This change was prompted by reports of Arctic Inuit hunters facing greater uncertainty with respect to environmental conditions each year.

Finally, the IWC adopted a limited automatic quota renewal process with safeguards for whale stocks to de-politicize the quota adoption process and allow for greater food security for subsistence harvesters. The plan adopted by the IWC would allow the previous catch limits to be automatically renewed if: (1) the Scientific Committee (SC) continues to advise that those catch limits will not harm the stock; (2) the ASW country receiving the quota has not proposed a change in their catch limits; and (3) the IWC determines that the ASW country has complied with the approved timeline of reporting requirements set for them and that the information provided represents a status quo continuation of the hunt (IWC 2018d).

These Schedule Amendments were adopted by a greater than 3/4 majority, with 58 countries in favor of adoption, seven against, and five abstentions. Opponents to the Amendments expressed support for the needs of indigenous subsistence harvesters, but remained concerned about the automatic renewal provision (IWC 2018a).

In 2018, the United States provided the SC of the IWC with a proposed management plan for a Makah subsistence hunt of ENP gray whales for review with respect to the conservation objectives of the IWC. The proposed plan reviewed by the SC matches the Preferred Alternative analyzed in this FEIS. The SC tested the proposed plan using a modeling framework developed as part of a previous rangewide review of gray whales, which took place from 2014-2018. The SC concluded that the Management Plan met the IWC's conservation objectives for ENP, WNP, and PCFG gray whales. The Aboriginal Subsistence Whaling Subcommittee of the IWC also reviewed the Makah Management Plan and endorsed the SC's report and recommendations (IWC 2018a), and the IWC endorsed the results, conclusions, and recommendations of the ASW Sub-committee and the SC.

Section 4

Environmental Consequences

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

4.0 ENVIRONMENTAL CONSEQUENCES

4.1 Introduction

This section examines the potential direct and indirect effects of the seven alternatives on each of the resources considered in this FEIS. Direct effects are those that are caused by the action and occur at the same time and place, while indirect effects are those that are caused by the action but occur later in time or are farther removed in distance and are reasonably foreseeable. Both adverse and beneficial effects are considered.

Section 2 described the No-action Alternative and six action alternatives, including the Preferred Alternative (Alternative 7 – Composite Alternative)), and Section 3 described the current condition of the resources that may be affected by the alternatives. Section 5 will address any cumulative effects that might occur when the direct and indirect effects of any of the alternatives are considered in the context of past actions, other contemporaneous actions, or reasonably foreseeable future actions.

For each resource, Section 3 included a regulatory overview that provided information about how that resource is managed, which informs the criteria presented in this section for evaluating effects of the alternatives. This information was provided for context, and it is not the purpose of this FEIS to resolve legal issues. Rather, the focus of this FEIS is to provide information to the decision-maker.

The six action alternatives examined vary primarily in the timing and location of the hunt, the number of strikes, and the limits on mortality of PCFG whales. One alternative also varies in the hunting methods (use of all motorized vessels versus a wooden canoe, Alternative 3), and two others vary in the duration of the waiver and regulations, as well as of any permits granted under a waiver (Alternatives 6 and 7). The principal components of timing, location, number of strikes, and PCFG mortality limits (described in Subsection 2.3.2.2, Gray Whale Hunt Details) are likely to influence the time of year the Tribe would hunt, the number of days the Tribe would hunt, and the number of whales the Tribe would likely kill and harvest. Also relevant to the analysis of effects is the number of times whales would be subjected to unsuccessful harpoon attempts, the number of times whales would be approached and potentially harassed by Makah vessels, and the number of rifle shots or grenade explosions under each alternative. Table 4-1 contains the same information regarding the principal components of the alternatives as that contained in Table 2-1, Primary Differences Among Alternatives, and also includes additional annual estimates of (1) the likely timing of the hunt, (2) the likely number of hunting days, (3) the maximum number of ENP

gray whales that might be killed, (4) the maximum and likely number of PCFG whales that might be killed, (5) the likelihood of killing a WNP whale, (6) the likely number of unsuccessful harpoon attempts, (7) the likely number of approaches, (8) the number of whales that might be successfully harvested, and (9) the likely number of rifle shots or grenade explosions. These estimates are based on the best available information and are relevant to evaluating the likely effects of the alternatives on most of the resources. The following discussion explains the basis for these estimates.

Also, the following definitions for the various groupings of whales analyzed in this section are provided below as a reminder for the reader (these terms are discussed in more detail in Subsection 3.4, Gray Whales, and are defined in the Glossary):

Western North Pacific (WNP) gray whales = Gray whales that feed during the summer and fall in the Okhotsk Sea (primarily off northeast Sakhalin Island, Russia), some of which also feed off southeastern Kamchatka in the Bering Sea. WNP gray whales are considered a population stock under the MMPA, and the stock is designated as depleted. WNP gray whales are recognized as a distinct population segment (DPS) under the ESA and are designated as endangered.

Eastern North Pacific (ENP) gray whales = Gray whales that feed during the summer and fall primarily in the Chukchi, Beaufort, and northwestern Bering Seas, but also as far south as California. ENP gray whales are considered a population stock under the MMPA. ENP gray whales were formerly listed as an endangered species under the ESA but subsequently recovered and were delisted in 1994 (59 FR 31094, June 16, 1994).

Pacific Coast Feeding Group (PCFG) whales = Gray whales observed in at least 2 years between June 1 and November 30 in the PCFG area (along the U.S. and Canada coasts between 41°N and 52°N, excluding areas in Puget Sound) and entered into the Cascadia Research Collective's photo-identification catalog. For purposes of determining whether a harvested whale is a PCFG whale and therefore counts against a bycatch or mortality limit, the Tribe's proposal under Alternative 2 would include cataloged whales seen in at least 1 year, while the other action alternatives would include cataloged whales seen in 2 or more years. Alternative 7, the preferred alternative, would assume any whale struck, struck and lost, or approached during the summer hunt time period to be a PCFG whale. Under the MMPA, PCFG whales are considered part of the ENP gray whale population stock and have been described in the ENP gray whale SARs as a feeding aggregation.

Oregon to Southern Vancouver Island (OR-SVI) whales = PCFG whales observed in any survey area from southern Oregon to southern Vancouver Island (excluding areas in Puget Sound) from June 1 to November 30. This grouping comprises individual PCFG whales sighted in the relevant survey areas and is not a separate population stock or feeding aggregation.

Makah U&A whales = PCFG whales observed in either the northern Washington survey area (from Cape Alava to Cape Flattery) or Strait of Juan de Fuca survey area (from Cape Flattery to Admiralty Inlet) from June 1 to November 30. This grouping comprises individual PCFG whales sighted in the relevant survey areas and is not a separate population stock or feeding aggregation.[1]

[1] Identified survey area boundaries are taken from Calambokidis et al. (2019). Survey effort and whale sightings can be opportunistic and not uniformly distributed within these boundaries.

Table 4-1. Primary differences among alternatives and associated assumptions for analysis.

Whale Hunting Components		Alt. 1 No Action	Alternative 2 Tribe's Proposed Action	Alternative 3 Offshore Hunt	Alternative 4 Summer/Fall Hunt	Alternative 5 Split Season Hunt	Alternative 6 Different Limits on Strikes and PCFG, and Limited Duration of Regulations and Permits	Alternative 7 Composite – Preferred
Hunt timing		None	December 1 through May 31[a]	Same as Alternative 2	June 1 through November 30	December 1 through December 21; May 10 through May 31	Same as Alternatives 2 and 3	Summer/fall hunts and hunting approaches will be authorized from July 1 through October 31, and winter/spring hunts and hunting approaches will be authorized from December 1 through May 31. Only one hunt season may be authorized in a calendar year, however the first month (December) of a winter/spring hunt would fall in the same calendar year as a summer/fall hunt.
Hunt area		None	U&A west of Bonilla-Tatoosh line; no whale may be struck within 200 yards (182.9 m) of Tatoosh Island or White Rock during the month of May	Same as Alternative 2 except at least 5 miles (8 km) from shore	Same as Alternative 2 except no whale may be struck within 200 yards of Tatoosh Island or White Rock during any month	Same as Alternative 2	Same as Alternatives 2 and 5	U&A west of Bonilla-Tatoosh line, with other site and time restrictions possible to protect Olympic Coast National Marine Sanctuary resources
Maximum limit for harvested, struck, and struck and lost whales	Annual	0	Up to 5 harvested, 7 struck, and 3 struck and lost	Up to 5 harvested, 6 struck, and 2 struck and lost	Up to 5 harvested, 7 struck, and 3 struck and lost; harvest, struck, and struck and lost limited by PCFG limit (see below)	Up to 5 harvested; struck and struck and lost limited by PCFG limit (see below)	Up to 4 harvested (7 over 2 years); up to 4 struck (7 over 2 years); struck and lost limited by strike limit or PCFG limit (see below)	In winter/spring hunts, up to 3 harvested, struck, or struck and lost. In summer/fall hunts, only 1 harvested and 2 struck or struck and lost

	6-year	0	Up to 24 harvested, 42 struck, and 18 struck and lost	Up to 24 harvested, 36 struck, and 12 struck and lost	Up to 24 harvested, 42 struck, and 18 struck and lost; harvest, struck, and struck and lost limited by PCFG limit (see below)	Up to 24 harvested; struck and struck and lost limited by PCFG limit (see below)	Up to 21 harvested, 21 struck; struck and lost limited by PCFG limit (see below)	Up to 12 harvested, and 15 struck or struck and lost
	10-year	0	Up to 40 harvested, 70 struck, and 30 struck and lost	Up to 40 harvested, 60 struck, and 20 struck and lost	Up to 40 harvested, 70 struck, and 30 struck and lost; harvest, struck, and struck and lost limited by PCFG limit (see below)	Up to 40 harvested; struck and struck and lost limited by PCFG limit (see below)	Up to 35 harvested, 35 struck; struck and lost limited by PCFG limit (see below)	Up to 20 harvested, and 25 struck or struck and lost
ENP Population Abundance Threshold		N/A	N/A	N/A	N/A	N/A	N/A	The impacts of the Preferred Alternative are analyzed without an ENP population abundance threshold. However, three thresholds are considered as sub-alternatives. Under the sub-alternatives, hunting would cease if the abundance estimate (N) of the ENP gray whale stock dropped below: a) N=11,000, b) N=16,000, or c) N=18,000

Additional limits on harvest or mortality of PCFG whales. Estimated limits are based on current conditions and could change based on updated information. The descriptions in the table are shorthand. Please refer to the narrative for full details, and Subsection 3.4.2.1.3, for background on the potential biological removal (PBR) approach.	N/A	Tribe's bycatch proposal (apply PBR-based formula, with Rmax of 4% and Recovery Factor same as for ENP (1.0) and Nmin of OR-SVI) (results in about 3.0 whales/year); struck but not landed do not count as PCFG; no carry-over of unused limit	Total mortality limit set at PBR (as reported in NMFS' stock assessment report or calculated by NMFS); additional female mortality limit set based on proportion of females in PCFG (results in about 2.7 males and 1.6 females); all struck but not landed count as PCFG whales in proportion to presence of PCFG whales; no carry-over of unused limit	Mortality limit set to achieve or maintain 80% of carrying capacity (PBR-based formula with same values as Alt 3 but a recovery factor of 0.35), minus other human-caused mortality (results in 1 whale); approach only known ENP males; all strikes count as PCFG; no carry-over of unused limit unless it's between 0.5 and 1.0	Mortality limit set at 10% of PBR as calculated in Alt 3 (results in about 1 whale/4 years); struck but not landed count as PCFG in proportion to presence of PCFG whales; carry-over of unused limit used to calculate hunt hiatus	Mortality limit set at PBR (as calculated in Alt 3) minus other human-caused mortality (results in about 2 whales/year); all struck but not landed count as PCFG in proportion to presence of PCFG whales; no carry-over of unused limit	Mortality limit set at 16 PCFG whales over 10 years, no more than 8 of which may be females. Hunting would be prohibited if the abundance of the PCFG falls below 192 whales, or the minimum abundance falls below 171 whales
Waiver and permit duration and additional regulations	N/A	Unlimited waiver period; up to 5-year permits; no additional regulations	Same as Alternative 2	Same as Alternatives 2 and 3	Same as Alternatives 2, 3, and 4	Waiver period ends after 10 years; 3-year permits	Waiver period ends after 10 years; initial permit ≤3 years, subsequent permits ≤5 years
ESTIMATES FOR ANALYSIS							
Whale Hunting Components		**Alternative 1 No-action**	**Alternative 2 Tribe's Proposed Action**	**Alternative 3 Offshore Hunt**	**Alternative 4 Summer/Fall Hunt**	**Alternative 5 Split Season Hunt**	**Alternative 6 Different Limits on Strikes and PCFG, and Limited Duration of Regulations and Permits**	**Alternative 7**
Likely timing of hunt		NA	March-May	March-May	June 1-September 30	May 10 through May 31	Same as Alternatives 2 and 3	March-May in winter/spring hunt years; July 1-October 31 in summer/fall hunt years
Likely number of hunting days per year		0	33	33 (with an additional 9 days possible during winter months)	7 every 2 years	11	Same as Alternative 2	33 in winter/spring hunt years; 7-14 in summer/fall hunt years

Likely number of days with hunt-related trips (including scouting) per year	0	60	Same as Alternative 2	7 every 2 years	22	Same as Alternatives 2 and 3	60 in winter/spring hunt years; 7-14 in summer/fall hunt years; Average of up to 37 per year over 10 years
Maximum number of ENP gray whales killed each year by Makah Tribe (based on current estimates of PCFG mortality limits)	0	7 based on strike limit	6 based on harvest limits and current estimates of PCFG mortality limits	1 every 2 years based on current estimates of PCFG mortality limits	5 based on harvest limits and current estimates of PCFG mortality limits	7 over 2 years, no more than four in 1 year (based on strike limit)	3 based on strike limits in winter/spring hunts; 2 based on strike limits in summer/fall hunts (if the first whale struck is lost)
Maximum number of PCFG whales that might be killed in a year (based on current estimates of PCFG mortality limits) and likely number killed per year	0	Maximum: 3 Likely: 1.9	Maximum: 4 Likely: 1.6	Maximum: 1 every 2 years Likely: 1 every 2 years	Maximum: 1 Likely: 0.2 (1 every 5 years)	Maximum: 1 Likely: 0.96	Winter/spring hunts Maximum: 3 Likely: 0.82 Summer/fall hunts Maximum: 2 Likely: 2 (assumes the first struck whale is lost)
If maximum number of strikes occur, likelihood of striking a WNP whale per year expressed as the median probability, given an ENP abundance of 11,000 to 16,000 animals	0	0.056-0.084	0.048-0.072	0	0.040-0.060	0.028-0.042	0.024-0.035
Potential maximum number of unsuccessful harpoon attempts per year (based on estimated 6:1 ratio of unsuccessful harpoon attempts to successful strikes)	0	42	36	6 every 2 years	30	21	18 in winter/spring hunts; 12 in summer/fall hunts; Average of 15 per year over 10 years
Potential maximum number of approaches per year[b] (based on estimated 8.3 approaches per day of hunting)	0	353	Same as Alternative 2	58 every 2 years	122[c]	Same as Alternatives 2 and 3	353 (based on Alternative 2's maximum value)
Likely number of whales successfully harvested on average per year (based on current population estimates and calculations, and other conditions specific to each alternative)	0	up to 4	Same as Alternative 2	0.5	0 – 1	up to 3.5	Up to 3 in winter/spring hunts; up to 1 in summer/fall hunts

Likely number of rifle shots or grenade explosions per year (based on estimated 16 rifle shots and 3 grenade explosions per harvested whale)	0	Up to 64 rifle shots or 12 grenade explosions	Same as Alternative 2	0 – 16 rifle shots or 0 – 3 grenade explosions every 2 years	0 – 16 rifle shots or 0 – 3 grenade explosions	Up to 56 rifle shots or 11 grenade explosions	Up to 48 shots and 9 explosions in winter/spring hunts; up to 32 shots and 6 explosions in summer/fall hunts: Average of 40 shots and 7.5 explosions per year over 10 years

a. With this and other alternatives, we rely on calendar year ("per year") calculations and estimates to simplify comparisons in this FEIS.
b. The analysis also considers the likely number of approaches and attempted strikes per year for PCFG, OR-SVI, Makah U&A, and WNP gray whales. Those estimates are reported in Tables 4-4, 4-6, 4-8, 4-10, and 4-12.
c. Based on a maximum of 14.7 hunt days in May and December.

4.1.1 Alternative 1, No Action

Under Alternative 1, NMFS would not authorize a Makah gray whale hunt.

4.1.1.1 Potential Timing of a Hunt and Number of Hunting Days

Because no hunt would be authorized under Alternative 1, there would be no hunting season in the Makah U&A.

Because no hunt would be authorized under Alternative 1, there would be no hunting days in the Makah U&A.

4.1.1.2 Potential Number and Types of Vessels

Because no hunt would be authorized under Alternative 1, there would be no hunting vessels in the Makah U&A.

4.1.1.3 Potential Number of ENP and PCFG Whales Killed; Likelihood of Striking a WNP Whale; Likely Number of Whales Harvested

Because no hunt would be authorized under Alternative 1, there would be no whales killed as a result of hunting in the Makah Tribe's U&A. For the reasons described below, the entire ENP gray whale quota would likely be killed even though there would be no harvest by the Makah Tribe.

The current annual and 7-year catch limits set by the IWC for ENP gray whales are based on a joint request of the Russian Federation and the United States (see Subsection 3.17.3.2.2, Aboriginal Subsistence Whaling, for more detail about the joint request). The current landing limit set by the IWC is 980 whales over the 7-year period (2019 through 2025), with no more than 140 whales struck in any one year. A bilateral agreement between the Russian Federation and the United States, renewed each year, allocates those totals between the two countries. If we do not authorize a Makah gray whale hunt, or we authorize a hunt for fewer whales than provided in the most recent bilateral agreement, the agreement provides that "either side may initiate discussions on the transfer of unused takes from one Native group to another," (Fominykh and Wulff 2023). If a transfer is agreed to, the Russian Federation could authorize the Chukotka Natives to take any of the unused catch limit. There are several reasons to expect that such transfer would occur and that the Chukotka Natives would harvest any unused Makah allocation. First, the first joint request by Russia and the United States for a gray whale catch limit was for the same catch limit that had previously been adopted in response to the Russia-only request (in other words, the U.S. allocation came out of the existing Russian allocation) (Subsection 1.4.1.2.2, Overview of Requests for ENP Gray Whales on Behalf of the Makah). The catch limit for gray whales, based on the needs of the Chukotka Natives alone, was 179 whales annually prior to 1991, 169 whales annually from 1992 through 1994, and 140 whales annually from 1995 through 1997. Second, the

United States agreed to such a transfer of unused takes of gray whales from the Makah Indian Tribe to Chukotka Natives in 2007, 2012, 2016, and 2017 (Ilyashenko and Hogarth 2007; Ilyashenko and DeMaster 2012; Fominykh and Smith 2016; Wulff and Fominykh 2017). Third, for the period 2018 through 2021 the Chukotka Natives harvested nearly all of the IWC catch limit (an annual average of 126.7) and went over their allocation of 135 whales in 2019 and 2020, harvesting 137 and 136 gray whales in those years respectively (IWC 2022d). For these reasons, it is reasonable to expect that if the Makah Tribe's request is denied, authorized at a lower limit, or the Tribe is unable to use its entire allocation, any unused allocation would be transferred to and used by the Chukotka Natives.

Thus, although the alternatives considered in this FEIS may result in the Makah Tribe harvesting different levels of ENP gray whales, the overall harvest of ENP gray whales is likely to be the same regardless of the alternative selected (that is, the total allowed under the IWC schedule). The difference would be how and where whales are killed, i.e., Makah using large caliber rifles in their U&A versus Chukotkans using smaller caliber rifles on their more northern hunting grounds. Where appropriate, the analysis notes the likely impact on a resource in the event the United States did not transfer any unused portion of the catch limit.

Beyond 2025, if we did not authorize a Makah gray whale hunt, it is reasonable to expect that the Russian Federation would request a renewal of the ENP gray whale catch limit of at least 744 whales over 6 years, consistent with their representations at the 2018 IWC meeting that their needs are greater than the total existing allocation (IWC 2023b).

It is unlikely that any PCFG whales would be killed in a hunt under Alternative 1 because there would be no hunting in the Makah U&A and all aboriginal subsistence whaling would occur in Russian waters.

4.1.1.4 Potential Number of Unsuccessful Harpoon Attempts and Approaches

Because no hunt would be authorized under Alternative 1, no whales would be subjected to attempted strikes or approaches by hunters in the Makah U&A.

4.1.1.5 Potential Number of Shots Fired or Grenade Explosions

Because no hunt would be authorized under Alternative 1, there would be no shots fired or grenades exploded by hunters in the Makah U&A.

4.1.2 Alternative 2, Tribe's Proposed Action

Alternative 2 represents the Makah Tribe's proposal, with a minor modification to reflect the change in the IWC aboriginal subsistence whaling schedule from 5-year to 6-year catch limits[2] (Subsection 1.4.1.2.2, Overview of Requests for ENP Gray Whales on Behalf of the Makah). Alternative 2 would authorize a hunt in the coastal portion of the Tribe's U&A (outside the Strait of Juan de Fuca) from December 1 through May 31. It would also prohibit striking whales within 200 yards (183 m) of Tatoosh Island and White Rock during May to minimize disturbance to feeding and nesting seabirds. There would be a limit of 7 whales struck per year, 5 whales harvested per year, 24 whales harvested over 6 years, and 3 whales struck and lost per year. There would be a limit on the number of PCFG whales harvested, which would be calculated using a PBR-based formula (described in more detail below and displayed in Table 4-3). As noted in Subsection 3.4.3.4.1, PCFG Population Structure, under the Tribe's proposal any harvested whale that had been sighted in the PCFG seasonal range (even a whale only sighted once) would count against the PCFG limit. However, the Tribe does not propose to count struck and lost whales against the PCFG limit. Hunting methods would include the use of a wooden canoe, toggle-point harpoon, and .50 caliber rifle. An optional method of killing whales would be the use of a darting gun and penthrite grenade (though this option was not included in the Tribe's request). The regulatory framework under Alternative 2 would include no termination date for the authorization and regulations and allow up to 5-year permits to be issued. These and additional details are described in Subsection 2.3.2.2, Gray Whale Hunt Details.

4.1.2.1 Potential Timing of a Hunt and Number of Hunting Days

Under Alternative 2, the hunting season would be December 1 through May 31. The environmental factors most likely to determine the timing of a hunt and the number of hunting days under Alternative 2 are: (1) ocean conditions favorable for scouting and locating whales, and (2) presence of whales. Social, economic, or other factors may further limit the number of days tribal members might hunt, but those factors are too speculative to evaluate.

The ocean conditions that are favorable for a hunt are wind speeds less than 16 knots (8.2 m/s) and wave height less than 6 feet (1.8 m). At wind speeds higher than 16 knots or waves higher than 6 feet, it becomes difficult to detect whales because their blows are quickly dispersed by the wind, it is difficult to observe them over the swells, and the boat operator must focus attention on navigation rather than scanning for whales (J. Scordino, pers. comm., Makah Tribe Marine Mammal Biologist, July 31, 2013)

[2] Although the current IWC quota block is set for a 7-year period to shift the expiration of the quota period to one year after Commission meeting years, the quota blocks will return to 6-year periods beginning in 2025 (see Subsection 3.17.3.2.2, Aboriginal Subsistence Whaling, for more information). The 6-year period was selected for analyzing the impacts of the alternatives in this analysis to align with the long-term IWC process.

(refer to Subsection 3.4.3.5.7, Weather and Sea Conditions). On days with favorable ocean conditions, tribal hunters would likely only launch a hunt if at least one whale were present in the hunt area. We thus consider a "suitable hunting day" to be one with these favorable ocean conditions and one or more whales present.

We examined data from a weather buoy stationed near the hunt area to determine the number of days by month with favorable ocean conditions. The Makah Tribe and the National Marine Mammal Laboratory provided data from their survey efforts in the hunt area to estimate the probability of whales being present per survey trip. We considered this a reasonable surrogate for the probability of whales being present during a hunt; that is, the probability that tribal hunters would successfully locate whales. Table 4-2 shows the number of days with favorable ocean conditions and the probability that whales would be present on any day. The final column shows the product of these values, which is the number of suitable hunting days per month.

Table 4-2. Projected number of days during the hunting season with favorable ocean conditions and whales present.

Month	A. Number of Surveys with 1 or More Gray Whale Sightings	B. Number of Surveys with no Sightings of Gray Whales	C. Total Number of Ocean Surveys (A+B)	D. Probability of Sighting 1 or More Gray Whales (A/C)	E. 2004-2012 Average Number of Days with Favorable Ocean Conditions	Projected Suitable Hunting Days (DxE)
Jan	2	1	3	0.67	5.2	3.5
Feb	1	3	4	0.25	6.3	1.6
Mar	8	2	10	0.80	6.8	5.4
Apr	18	1	19	0.95	13.8	13.0
May	17	9	26	0.65	22.7	14.8
Jun	14	2	16	0.88	24.3	21.3
Jul	18	3	21	0.86	27.0	23.1
Aug	24	4	28	0.86	28.5	24.4
Sep	23	1	24	0.96	21.3	20.4
Oct	14		14	1.00	12.3	12.3
Nov	5	3	8	0.63	5.4	3.4
Dec	3	1	4	0.75	5.6	4.2

Under the Tribe's proposed action, we expect the majority of hunting to occur in April and May because those are the months with the greatest number of suitable hunting days[3], with about 13 days in April and about 15 days in May. Tribal members may also try to maximize hunting opportunity by hunting during March, with about 5 suitable hunting days. In total, there could be up to 33.2 days of hunting per year during the spring under Alternative 2 (5.4 + 13.0 + 14.8 = 33.2). We consider it less likely that tribal members would hunt in December through February, when there are only a total of 9.3 suitable hunting days during the entire 3-month period (4.2 + 3.5 + 1.6 = 9.3). However, it is possible a hunt may occur during this time period, so we consider it in the analysis. If tribal members hunted on every suitable hunting day during December through May, that would equal about 42.5 days of hunting per year under Alternative 2 (33.2 + 9.3 = 42.5).

For a variety of reasons, this number may be an overestimate of the number of days tribal members would actually hunt. As noted, social and economic factors may result in tribal members not hunting on all suitable hunting days. Tribal members might also be able to harvest the average annual quota of four whales in fewer than the 42.5 suitable hunting days available each year. During 1999, the Tribe successfully hunted a single whale during 4 days of hunting. During the 2000 hunt, the Tribe hunted for 7 days without harvesting any whales. We conclude that this experience does not provide enough of an indication of how many days would be required for the Tribe to harvest a whale in the future, both because it is inconclusive (one data point of 4 days per whale harvested and another data point of 7 days and no whales), and because a hunt under current conditions may be different than the hunts during 1999 and 2000, primarily because of the knowledge of whales gained through the Tribe's extensive survey efforts in the intervening years. Therefore, we did not reduce the number of potential hunting days based on an estimate of average number of days per whale harvested.

In addition to the number of days in which tribal members would hunt from a canoe with support vessels, under Alternative 2 there may be days in which a motorized vessel scouts for whales and days when tribal members conduct training activities from motorized vessels and canoes. We assume scouting and training may occur on every day with favorable ocean conditions. During March through May, there are approximately 43.3 days with favorable ocean conditions (6.8 + 13.8 + 22.7 = 43.3); thus, we assume there could be 43.3 days of scouting effort or during the spring. If tribal members chose to hunt during December through February as well, there could be an additional 17.1 scouting

[3] While June through September have a greater number of suitable days, these months are outside the hunt season (December 1 through May 31) under Alternative 2.

and/or training days with favorable ocean conditions (5.6 + 5.2 + 6.3 = 17.1), for a total of 60 possible days of hunt-related trips (including scouting effort and training) from December through May. This number may also be an overestimate of the number of days the Tribe would actually train or scout for whales, in part for the same reasons that our estimate of hunting days may be an overestimate, and in part because tribal members may scout whales opportunistically while engaged in other activities, rather than mount a dedicated scouting effort.

To summarize, we expect the maximum number of days of hunting, training, and scouting under Alternative 2 to occur as follows:

- Most likely: March through May
    - 43.3 scouting and/or training days, 33.2 hunting and/or training days
- Less likely: December through February
    - 17.1 scouting and/or training days, 9.3 hunting days

4.1.2.2 Potential Number and Types of Vessels

Under Alternative 2, the Tribe would hunt from a wooden canoe (which would carry the harpooner and crew) and a motorized chase vessel (which would carry the rifleman, backup harpooner, and diver), with one of these vessels also carrying the whaling captain. It is likely that other vessels would be involved in the hunt, at least during the first few years of hunting. Similar to the 1999 hunt, such vessels could include a NOAA or Makah research vessel, a Coast Guard enforcement vessel, one or more vessels chartered by the media, and protest vessels (Subsection 1.4.2, Summary of Recent Makah Whaling — 1998 through 2022). It is difficult to predict the number of protest vessels, but it is likely there would be several that would accompany at least some hunt excursions, including small craft and jet skis, as was the case during the 1999 hunt. There also may be helicopters, similar to those chartered by the media during the 1999 hunt.

4.1.2.3 Potential Number of ENP and PCFG Whales Killed; Likelihood of Striking a WNP Whale; Likely Number of Whales Harvested

Potential Number of ENP Whales Killed

Under Alternative 2, the maximum number of whales that could be killed each year by the Tribe would be seven, because of the limit of seven strikes per year. This estimated maximum assumes that struck and lost whales subsequently die. A total mortality of up to 7 whales per year represents 0.048 percent of the ENP gray whale population (estimated to be 14,526 whales) and 1.7 or 3.4 percent of PBR (based on the informational estimates of PBR or 409 and 204, calculated in Subsection 3.4.3.3.4 ENP Status, Carrying Capacity, and Related Estimates). This level of annual mortality, although higher than

under the No-action Alternative, is such a small fraction of the stock's abundance that it would not be likely to have a discernable effect on the ENP stock's abundance or rate of growth or on the stock's abundance relative to OSP.

Maximum and Likely Number of PCFG, OR-SVI, and Makah U&A Whales Killed

Some of the whales killed might be PCFG whales; and, of those, some might be whales previously documented occurring within the OR-SVI and the Makah U&A survey areas. Under Alternative 2, the Tribe proposes to stop hunting in any year if it harvests a calculated limit of PCFG whales. The Tribe proposes that this limit be calculated using NMFS' PBR methodology, based on the minimum abundance of whales previously sighted in the OR-SVI, using a recovery factor of 1.0, and an Rmax of 4 percent.[4] If this results in a fractional number, the harvest limit would be rounded down. Table 4-3 illustrates how the limit would be calculated. Under current conditions, the harvest limit would be 3.0 PCFG whales annually. Because the Tribe proposes to calculate and set the PCFG harvest limit each year, fractions of whales or unused whales would not be carried over to a subsequent year.

Table 4-3. Alternative 2 (Tribe's Proposed Action) method of calculating PCFG harvest limits.

Element	Current Value	Source for Establishing Value in Future Calculations	Notes
One-half maximum net productivity rate (Rmax)	(½) 0.040 = 0.02	IWC 2012e (Annex D)	See Subsection 3.4.3.4.4, PCFG Status, Carrying Capacity (K), and Related Estimates
Minimum population abundance of OR-SVI (Nmin)[a]	190	Harris et al. 2022	See Subsection 3.4.3.4.3, PCFG Abundance and Trends
Recovery factor for ENP stock as a whole	1.0	IWC 2012e (Annex D)	See Subsection 3.4.3.4.4, PCFG Status, Carrying Capacity (K), and Related Estimates
CURRENT RESULT	(0.02) * (190) * 1.0 = **3.8 (rounded down to 3)**		

[a] The value for Nmin is derived from photo-identification analyses of PCFG whales and may change as new information becomes available. The method for calculating the PCFG limits under Alternative 2 is described in Subsection 2.3.2.2.3, Limits on Harvesting PCFG Whales.

[4] Values for Rmax and the recovery factor are those submitted by the Makah Tribe to the IWC during the 2012 workshop focusing on the PCFG gray whale implementation review (IWC 2012e, Annex D). The 4 percent Rmax value used in that review was lower than the 4.7 percent used in the Tribe's 2005 waiver application to NMFS. We reviewed the differing values with the Tribe and determined that Alternative 2 (the Tribe's Proposed Action) should be interpreted as using an Rmax of 4 percent in keeping with the analysis and findings of the IWC Scientific Committee's 2012 review.

The Tribe proposes to count against the harvest limit only whales that are successfully landed and identified, not those that are struck and lost. Some proportion of struck and lost whales might, however, be PCFG whales. With an average allowable harvest limit of three PCFG whales landed, and a restriction of three whales struck and lost per year, a maximum of five PCFG whales might be killed each year (of which some or all might be OR-SVI and Makah U&A whales). This would happen if two PCFG whales were struck and lost (and not counted against the harvest limit) before three PCFG whales were landed and identified.[5]

While five would be the *maximum* number of PCFG whales that might be killed each year under Alternative 2, it is unlikely that many would actually be killed given that there is a greater proportion of non-PCFG whales present in the Makah U&A during the spring portion of the hunting season when the Tribe is most likely to hunt. The proportion of PCFG whales in the Makah U&A during the December through February portion of the winter hunting season is unknown (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). This analysis therefore also considers the *likely* number of PCFG whales that might be killed per year if the full number of strikes were to occur during the spring. The calculation is based on the proportional presence of PCFG whales in the coastal portion of the Makah U&A during March through May. In addition, the analysis considers the likely number of OR-SVI and Makah U&A whales that might be killed in a tribal hunt if the full number of strikes were to occur during the spring portion of the hunting season.

During the period 1996 to 2016, 27.3 percent of whale sightings (unique whale-days) during the March through May period in the northern Washington coast survey area were PCFG whales, 26.2 percent were also OR-SVI whales, and 23.4 percent were also Makah U&A whales (Calambokidis et al. 2019; Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). Although Harris et al. (2022) used the same methods as Calambokidis et al. (2019) to update these mixing proportions with data from 2017 to 2022, these data were selectively processed in a manner which resulted in a known bias. Therefore, Harris et al. (2022) recommend relying on the previous mixing proportions until future reporting is complete (see Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). If seven whales were killed in a year under Alternative 2, the likely number of PCFG whales that would be killed would be 1.9 (7 whales killed times 27.3 percent), the likely number of OR-SVI whales killed would be 1.8 (seven whales killed times 26.2 percent), and the likely number of Makah U&A whales killed would be 1.6 (seven whales killed times 23.4 percent). These numbers are

[5] These maximum estimates are based on the unlikely assumption that all struck and lost whales are PCFG whales that subsequently die from such injury. It is possible that a harvested PCFG whale is falsely thought to be a non-PCFG whale because it is either mismatched or a match to the catalog is not found (J. Calambokidis, pers. comm., Cascadia Research Collective, May 14, 2014). Such cases (i.e., false negatives) are extremely rare and not included in our estimates.

subsets of one another (as shown in Figure 3-10, the OR-SVI is contained in the PCFG area and the Makah U&A is contained in the OR-SVI area) so are not additive. These estimates are also displayed in Table 4-4. This level of mortality for the PCFG is below the informational PBR of 3.1 whales calculated by NMFS (Harris et al. 2022). If the Tribe also hunted in the winter, it is uncertain what the proportion of PCFG whales would be; thus, there could be more or fewer PCFG, OR-SVI, or Makah U&A whales killed.

Likelihood of Striking a WNP Whale

Finally, the analysis considers the likelihood that a WNP whale may be killed in a single year and over a 6-year and 10-year period. There are very limited data for WNP whales in the action area to inform this analysis (Subsection 3.4.3.2.2, WNP Seasonal Distribution, Migration, and Movements). Table 4-4 shows the calculated probability, displayed as the median estimate, of a WNP whale being struck based on seven strikes per year during the spring using estimates derived from modeling by Moore et al. (2023), and strike/attempt/approach estimates specific to this alternative.

Based on the best available information and taking the conservative approach of assuming the greatest possible impact, Moore et al. (2023) assumed (1) that all allowable strikes, approaches, and training harpoon throws would be utilized in a given year and (2) that they would all be made on unique whales (meaning, for example, that all 353 allowable approaches in a given year are made on 353 different whales). Given these assumptions, they estimate that for an individual strike on a gray whale, the expected probability of it being a WNP whale is between 0.8% and 1.2%, assuming an ENP abundance of between 16,000 and 11,000 animals[6], respectively. It is unlikely that all of the assumptions of this analysis will be met, as it is unlikely that the full allowance of strikes, training harpoon throws, and approaches will be utilized each year. Therefore, the estimates derived here from the Moore et al. 2023 analysis represented the maximum potential impact to WNP gray whales under Alternative 2.

Likely Number of ENP Whales Harvested

Under Alternative 2, the Tribe would be authorized to harvest, on average, four whales per year, with a maximum of five whales in a year. Therefore, the average annual number of whales that could be harvested is at most four whales.

[6] Moore et al. (2023) chose to analyze a range of ENP abundance due to the ongoing decline of the ENP population and to provide a range of potential probabilities of encountering a WNP gray whale over the course of the 10-year waiver period should the decline continue. At the time the analysis was conducted, the most recent ENP abundance was estimated at approximately 16,000 whales (Eguchi et al. 2022a). The lower bound of 11,000 whale was selected as the lowest previously recorded abundance estimate for the ENP population (Moore et al. 2023).

4.1.2.4 Potential Number of Unsuccessful Harpoon Attempts and Approaches

In its waiver request, the Tribe referred to its experience in 1999 and 2000 to estimate there would be four unsuccessful harpoon attempts for each successful strike and 20 whales approached for each successful strike. Based on our review of the available data from the 1999 and 2000 hunts, and in particular the reports of the 1999 (Gosho 1999) and 2000 (Gearin and Gosho 2000) hunts, we have developed different estimates for this analysis.

To estimate the potential number of unsuccessful harpoon attempts for the action alternatives, we considered the Tribe's hunt experience from both 1999 and 2000. In 1999, tribal hunters made three unsuccessful harpoon attempts and one successful strike. Based on this information, the Tribe's application concluded there would be four unsuccessful harpoon attempts for each successful strike. However, the actual ratio experienced in the 1999 hunt was 3:1, not 4:1, because the fourth attempt was successful. The Tribe also hunted in 2000 and made three unsuccessful harpoon attempts and no successful strikes. Thus, the ratio of unsuccessful harpoon attempts to successful strikes from the combined 1999 and 2000 hunting seasons would be 6:1. This is the ratio we use to estimate the number of unsuccessful harpoon attempts.

The Tribe estimated that with 10 approaches for each whale struck there would be 20 whales approached because of the average pod size of two whales, as observed during the southbound counts at Granite Canyon. The Tribe's application does not explain the basis for the assumption that there would be 10 approaches for each whale struck.

For the analysis in this FEIS, we examined information from the 2000 hunt because the report of that hunt (Gearin and Gosho 2000) documents the actual number of whales encountered by tribal hunters. During the 2000 hunt, tribal hunters approached 58 whales over 7 hunting days, for an average of 8.3 whales approached per day. We therefore use an average of 8.3 approaches per hunting day for the analysis in this FEIS because it is based on actual counts of whales approached and does not rely on assumptions about average pod size of south-migrating whales, which may not hold true for north-migrating whales in the Makah U&A during the spring.

Under Alternative 2, with a maximum of seven possible strikes per year, there might be 42 unsuccessful harpoon attempts (seven strikes times six unsuccessful harpoon attempts). With up to 33.2 hunting days per year in the spring, the potential number of times that tribal hunters might approach a whale would be 276 (8.3 approaches per day times 33.2 days). If tribal members hunted during the winter as well, there could be an additional 77 approaches (8.3 per day times 9.3 days). Some of these attempted strikes and approaches could be repeated incidents involving the same whale. We also estimated the number of instances in which PCFG, OR-SVI, and Makah U&A whales could be

subjected to unsuccessful harpoon attempts or approaches by hunters. For these estimates, we multiplied the number of strikes and approaches times the proportion of each category of whales observed in the coastal portion of the Makah U&A during March through May (Subsection 3.4.3.4.3, PCFG Abundance and Trends). The estimates are displayed in Table 4-4.

Finally, we estimated the likelihood of an unsuccessful harpoon attempt or approach involving a WNP whale. For these estimates, we relied on modeling by Moore et al. (2023), as described above (Subsection 4.1.2.3, Potential Number of ENP and PCFG Whales Killed; Likelihood of Striking a WNP Whale; Likely Number of Whales Harvested). These are highly precautionary estimates of the maximum potential impact to WNP gray whales under Alternative 2, for the same reasons as described above in Subsection 4.1.2.3. The estimates are displayed in Table 4-4.

Table 4-4. Estimated number of strikes, unsuccessful harpoon attempts, and approaches of ENP, PCFG, OR-SVI, Makah U&A, and WNP whales under Alternative 2.

Whales		Number of Strikes[a]			Number of Unsuccessful Harpoon Attempts[b]			Number of Approaches[c]		
		Annual	**6-year**	**10-year**	**Annual**	**6-year**	**10-year**	**Annual**	**6-year**	**10-year**
ENP[d]		7	42	70	42	252	420	353	2,118	3,530
PCFG[e]	27.3%	1.9	11.5	19.1	115	68.8	114.7	96.4	578.2	963.7
OR-SVI[e]	26.2%	1.8	11.0	18.3	11.0	66.0	110.0	92.5	554.9	924.9
MUA[e]	23.4%	1.6	9.8	16.4	9.8	59.0	98.3	82.6	495.6	826.0
WNP[f]	0.8-1.2%	0.056-0.084	0.34-0.50	0.56-0.84	0.34-0.50	2.0-3.0	3.4-5.0	2.8-4.2	16.6-25.0	27.7-41.6

a. Limited by regulation.
b. Calculated using number of unsuccessful harpoon attempts per successful strike (6:1), based on experience during 1999 and 2000 hunts combined.
c. Calculated using an estimate of 8.3 approaches per day of hunting and a total of 42.5 hunting days per year.
d. ENP estimates are maximum values.
e. Percentage estimates are based on the springtime whale analysis by Calambokidis et al. (2019) that compares whales seen in the spring to the entire catalog of whales identified in the PCFG range during the summer/fall feeding period (in contrast to the definition we use in this FEIS for PCFG whales, which requires a whale to be have been seen in at least 2 years). This results in estimates that are likely higher and therefore more conservative than estimates that would be derived from a comparison with whales observed in at least 2 years. We conclude that this conservative approach is appropriate as it allows for the possibility that a whale sighted in the spring might later be seen for the second time in the PCFG seasonal range. Note that OR-SVI and MUA are nested regions within the PCFG range.
f. Range of median probability based on modeling by Moore et al. (2023) given an ENP gray whale population abundance range of approximately 11,000 to 16,000 animals.

4.1.2.5 Potential Number of Shots Fired or Grenade Explosions

The Tribe proposes to use a .50 caliber rifle to kill whales that have been struck and secured with a harpoon. During the 1999 hunt, the Tribe's rifleman shot four times to kill the whale that was harvested. During the unauthorized gray whale hunt in 2007, at least 16 shots were fired (Subsection 1.4.2, Summary of Recent Makah Whaling — 1998 through 2022). Because the 2007 hunt followed none of the procedures recommended by the Tribe—including the training requirements put in place to reduce time to death—and because the hunters switched to a .460 caliber rifle after losing the .577 caliber rifle overboard, this number of shots may be higher than what would be experienced in a regulated hunt. Chukotka Natives kill gray whales using smaller caliber rifles than proposed by the Tribe and have recently reported an average of 92 bullets per whale killed (Subsection 3.4.3.5.4, Method of Killing and Time to Death). For purposes of this analysis, we estimate that for each harvested whale there could be up to 16 shots fired, which is the number of shots fired during the unauthorized 2007 hunt. Under Alternative 2, the likely number of whales successfully harvested on average per year is four; thus, there could be up to 64 shots fired per year (16 shots times four whales harvested) and up to 384 shots over a 6-year period.

We estimate that, if the Tribe used explosive projectiles to strike and kill whales, a maximum of three grenades per whale would be detonated based on the experience of other aboriginal whale hunters (Subsection 3.4.3.5.4, Method of Killing and Time to Death). This would result in up to 12 explosions per year if up to four whales are successfully harvested annually (or 72 explosions over a 6-year period). It is possible that rifle shots and grenade explosions could result in behavioral disturbance of nearby whales. Grenade explosions may also cause temporary hearing threshold shifts in gray whales. However, it is unlikely that hunters would fire rifles or grenades at a whale before it has been "made fast" with a harpoon attached to a buoy. As a result, they can largely limit the impacts of gunshots and grenade explosions to the whale being harvested by first separating it from any nearby whales. In addition, effects would be related to the timing and location of the noise relative to the nearby whale's location and activity. Any noise from a gunshot would probably decay to ambient levels within 1 or 2 miles of the source, and the duration of the sound is expected to only last a few seconds. Given this, any disturbance from the use of weapons be temporary, and it is unlikely that these activities will have a discernable impact on the ENP gray whale stock's abundance, rate of growth, or distribution, or that these activities will affect their migration under Alternative 2.

It is also possible there could be shots fired or grenades exploded in conjunction with struck and lost whales, but we consider this unlikely because of the way "harvest" is defined. A whale is considered

harvested once a flag or buoy has been attached (essentially, once a harpoon is successfully embedded). It is unlikely that hunters would fire rifles or grenades at a whale before it has been "made fast" with a harpoon attached to a buoy (refer to the Glossary and Subsection 1.1.1, Summary of the Proposed Action).

4.1.3 Alternative 3, Offshore Hunt

Alternative 3 would have the same conditions as Alternative 2 regarding the hunting season, limits on the numbers of ENP whales harvested, hunting methods, and regulatory framework. Alternative 3 would also have the same hunt area as Alternative 2, except that it would prohibit Makah hunters from making an initial strike on a gray whale within 5 miles (8 km) of shore (Makah hunters and chase boats may nevertheless follow any struck whale trailing harpoon lines to dispatch it, regardless of distance to shore). Alternative 3 would also differ from Alternative 2 in the way in which the PCFG limit would be calculated, including a provision for female PCFG whales, and the way in which struck and lost whales would be counted against the limit (described in more detail below and displayed in Table 4-5), resulting in a limit of two struck and lost whales, compared to three under Alternative 2. To allow full consideration of different hunt methods, Alternative 3 also assumes that the Tribe would most likely conduct a motorized hunt and not use canoes, in contrast with the other action alternatives that all include the use of a wooden canoe. These and additional details are described in more detail in Subsection 2.3.2.2, Gray Whale Hunt Details.

4.1.3.1 Potential Timing of a Hunt and Number of Hunting Days

Under Alternative 3, the hunting season would be the same as under Alternative 2 (December through May), with the same expected ocean conditions. Because of the requirement that hunts be conducted at least 5 miles (8 km) from shore, for purposes of analysis we assume that under Alternative 3 the Tribe would most likely conduct a motorized hunt and not use canoes. Although the Tribe would use motorized vessels under Alternative 3, the same two conditions would determine the likely timing of a hunt and the number of hunting days—favorable ocean conditions and presence of whales.

The difference in hunting vessel might, however, result in a slightly different manner of hunting under Alternative 3 compared to Alternative 2. Under Alternative 2, we estimate that scouting and training might occur on any day with favorable ocean conditions but hunting would occur only on days in which scouts also located whales. In contrast, under Alternative 3, we expect that scouting, training, and hunting trips would be combined because hunters would use a motorized vessel and hunting would occur 5 miles (8 km) or more from shore. Therefore, considering the effort required to scout 5 miles (8 km) from shore, we assume that hunters would scout for whales on days with favorable ocean conditions and be prepared to harvest a whale if one were sighted. Thus, for Alternative 3, we assume that during March through May there would be 43.3 days of combined scouting, training, and hunting

(which is the total number of days with favorable ocean conditions during that period, as described in Subsection 4.1.2.1, Potential Timing of a Hunt and Number of Hunting Days) and that during December through February there could be an additional 17.1 days of combined scouting, training, and hunting (which is the total number of days with favorable ocean conditions during that period, as described in Subsection 4.1.2.1, Potential Timing of a Hunt and Number of Hunting Days). Together, these amount to 60 possible days of hunt-related trips (including scouting and training effort) from December through May.

To summarize, we expect days of combined scouting, training, and hunting under Alternative 3 to occur as follows:

- Most likely: March through May
    - 43.3 days combined scouting, training, and hunting days
- Less likely: December through February
    - 17.1 days combined scouting, training, and hunting days

4.1.3.2 Potential Number and Types of Vessels

Under Alternative 3, the Tribe would most likely not hunt from a wooden canoe, as they proposed, but from a motorized vessel which would carry the whaling captain, harpooner, and crew. A second motorized vessel would serve as the chase vessel and would carry the rifleman, backup harpooner, and diver. It is likely that other vessels would be involved in the hunt, at least during the first few years of hunting. Similar to the 1999 hunt, such vessels could include the Makah or NOAA research vessel, a Coast Guard enforcement vessel, one or more vessels chartered by the media, and protest vessels (Subsection 1.4.2, Summary of Recent Makah Whaling — 1998 through 2022). It is difficult to predict the number of protest vessels, but it is likely there would be fewer small personal craft (e.g., jet skis) than during the 1999 hunt because of the distance from shore. There also may be helicopters, similar to those chartered by the media during the 1999 hunt.

4.1.3.3 Potential Number of ENP and PCFG Whales Killed; Likelihood of Striking a WNP Whale; Likely Number of Whales Harvested

Potential Number of ENP Whales Killed

Under Alternative 3, the Tribe would be allowed only two struck and lost whales (in contrast to Alternative 2, which would allow three struck and lost) as explained in this subsection. Therefore, under Alternative 3, the maximum number of whales that could be killed in a year by the Tribe would be six. This maximum number would be reached in only two scenarios: (1) if the Tribe harvested four non-PCFG whales and struck and lost two whales (that subsequently died), or (2) if the Tribe harvested

five non-PCFG whales and struck and lost one whale (that subsequently died). The latter scenario could occur, at most, in 4 out of 6 years but could not occur every year, otherwise the Tribe would exceed the 6-year harvest limit of 24 whales. In the years in which the maximum mortality of 6 whales were achieved, hunt-related mortality would represent 0.041 percent of the ENP gray whale population (estimated to be 14,526 whales) and 1.5 or 2.9 percent of PBR (based on the informational estimates of PBR calculated in Subsection 3.4.3.3.4 ENP Status, Carrying Capacity, and Related Estimates). This level of mortality, although higher than under the No-action Alternative, would not be likely to have a discernable effect on the ENP stock's abundance or rate of growth or on the stock's abundance relative to OSP due to the small percentage of the stock that could be affected.

Maximum and Likely Number of PCFG, OR-SVI, and Makah U&A Whales Killed

Some of the whales killed under Alternative 3 might be PCFG whales, and, of those, some might also be OR-SVI and Makah U&A whales. Under Alternative 3, there would be a limit on the *total mortality* of PCFG whales, in contrast with Alternative 2, which would impose a limit on the *harvest* of PCFG whales. That is, under Alternative 3, struck and lost whales would count against the PCFG limit, while under Alternative 2 they would not. Under Alternative 3, the annual mortality limit for PCFG whales would be equal to NMFS' informational calculation of PBR for the PCFG in its most recent stock assessment report (Subsection 3.4.2.1.4, Defining and Calculating PBR). This alternative would also have an annual mortality limit on female PCFG whales to account for the possible importance of mothers in recruiting offspring to the PCFG via matrilineal site fidelity (Subsection 3.4.3.4.1, PCFG Population Structure). The annual female PCFG mortality limit would be equal to the total PCFG mortality limit times the proportion of females in the PCFG, which is currently estimated to be approximately 50% (Aimee Lang, pers. comm., Southwest Fisheries Science Center Biologist, February 26, 2020). Table 4-5 illustrates how the total PCFG and female PCFG mortality limits would be calculated. The mortality limit using the current values for the PBR formula would be 3.52 PCFG whales of which 1.76 (3.52 times 0.5) could be PCFG female whales. The hunt would stop before these limits were exceeded in any year. Because the mortality limit would be set each year, fractions of whales or unused whales would not be carried over to a subsequent year.

Table 4-5. Alternative 3 method of calculating PCFG mortality limits.

Element	Current Value	Source for Establishing Value in Future Calculations[a]	Notes
One-half maximum net productivity rate (Rmax)	(½) 0.062 = 0.031	NMFS' stock assessment report (Carretta et al. 2023)	See Subsection 3.4.2.1.4, Defining and Calculating PBR

Minimum population abundance of PCFG (Nmin)	227	NMFS' stock assessment report (Carretta et al. 2023)	See Subsection 3.4.3.4.3, PCFG Abundance and Trends
Recovery factor for PCFG	0.5	NMFS' stock assessment report (Carretta et al. 2023)	See Subsection 3.4.2.1.4, Defining and Calculating PBR
CURRENT RESULT	Total Mortality: (0.031) * (227) * 0.5 = **3.52** PCFG Female Mortality = 3.52 * 0.5 = **1.76**		

[a] Values for the elements used in this calculation would be derived from NMFS Stock Assessment Reports, the most recent of which is Carretta et al. (2023), as described under Subsection 2.3.3 Alternative 3 (Offshore Hunt). These values may change as new information becomes available.

Alternative 3 would count whales that are struck and lost against the PCFG mortality limit in proportion to the availability of PCFG whales in the coastal portion of the Makah U&A from March through May (currently0.273 PCFG whales, or 27.3 percent). It would also count a proportion of those whales as female PCFG whales based on the proportion of female whales in the PCFG during the feeding season (June through November). That proportion is currently 50 percent (Aimee Lang, pers. comm., Southwest Fisheries Science Center Biologist, February 26, 2020), with the result being that a struck and lost whale would count as 0.14 PCFG females (0.273 times 0.5). In addition, under Alternative 3 the Tribe would be limited to a maximum of two struck and lost whales per year (in comparison to the limit of three struck and lost whales proposed by the Tribe and considered under Alternative 2). Under this limit, striking and losing two whales would, on average, limit impacts on PCFG females to approximately one per year (0.53 PCFG females times two strikes).

Given these considerations and current estimates, the maximum number of PCFG whales that could be killed in a year under Alternative 3 would be four whales, at least one of which must be a struck and lost whale that is assumed to subsequently die. Also, the maximum of four whales can only occur (1) if a certain sequence of strikes occurs, and (2) a female PCFG whale is not one of the first three whales harvested. Using these conditions and the current estimates shown in Table 4-5, the following six sequences could result in the maximum four PCFG whales killed under this alternative (H = harvested whale is a landed, known PCFG whale that counts as 1.0 against the total mortality limit; S = struck and lost whale is presumed to be a PCFG whale that counts as 0.27 against the total mortality limit):

- HHSH or HSHH or SHHH = 3.27 (hunt stops because striking or harvesting another PCFG whale would exceed the total mortality limit of 3.5 PCFG whales)
- SHHS or HSHS or HHSS = 2.54 (hunt stops because the annual struck and lost limit is met)

In these scenarios, any number of non-PCFG whales could be landed, up to the maximum of five in one year or an average of four per year over 6 years.

While four would be the *maximum* number of PCFG whales that might be killed each year under Alternative 3, it is unlikely that four would actually be killed given the proportion of PCFG whales present in the Makah U&A during the spring portion of the hunting season when the Tribe is most likely to hunt (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). This analysis, therefore, also considers the *likely* number of PCFG whales that might be killed per year if the full number of strikes were to occur during the spring. The calculation is based on the proportional presence of PCFG whales in the coastal portion of the Makah U&A during March through May. In addition, the analysis considers the likely number of OR-SVI and Makah U&A whales that might be killed in a tribal hunt if the full number of strikes were to occur during the spring portion of the hunting season.

There are currently no data on the proportion of PCFG whales in the offshore hunt area under Alternative 3 because most surveys have been conducted closer than 5 miles (8 km) from shore (Subsections 3.4.3.3.2, ENP Seasonal Distribution, Migration, and Movements, Migratory Distribution Relative to Shore, and 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). For this analysis, we assume that PCFG whales would be present 5 miles (8 km) from shore in the same proportion they are present closer to shore. This may be a conservative assumption, as it is possible that migrating whales travel further from shore while PCFG whales travel closer to shore (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements).

During the period 1996 to 2016, 27.3 percent of whales identified from March through May in the northern Washington coast survey area were PCFG whales, 26.2 percent were OR-SVI whales, and 23.4 percent were Makah U&A whales (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). Under Alternative 3, if a maximum of six ENP whales were struck or killed in a year during the spring, the likely number of PCFG whales that would be struck or killed would be 1.64 whales (six whales times 27.3 percent), the likely number of OR-SVI whales struck or killed would be 1.57 (six whales times 26.2 percent), and the likely number of Makah U&A whales struck or killed would be 1.40 (six whales times 23.4 percent). These numbers are subsets of one another (the OR-SVI is contained in the PCFG area and the Makah U&A is contained in the OR-SVI area) (Figure 3-10) so are not additive. These estimates are also displayed in Table 4-6.

If the Tribe also hunted in the winter, it is uncertain what the proportion of PCFG whales would be; thus, there could be more or fewer PCFG, OR-SVI, or Makah U&A whales killed. However, because a

proportion of all struck and lost whales would be counted against the PCFG limit, the maximum number of PCFG whales that could be killed per year would be four (as described above).

Likelihood of Striking a WNP Whale

Finally, the analysis considers the likelihood that a WNP whale may be killed in a single year and over a 6-year period. There are very limited data for WNP whales in the action area to inform this analysis (Subsection 3.4.3.2.2, WNP Seasonal Distribution, Migration, and Movements). Table 4-6 shows the calculated probability of a WNP whale being struck based on six strikes per year during the spring, using estimates derived from modeling by Moore et al. (2023). These are highly precautionary estimates of the maximum potential impact to WNP gray whales under Alternative 3, for the same reasons as described under Alternative 2 in Subsection 4.1.2.3.

Likely Number of ENP Whales Harvested

As under Alternative 2, the Tribe, under Alternative 3 , would be authorized to harvest a maximum of five whales in a single year or 24 whales over a 6-year period (i.e., an average of four whales harvested per year).

4.1.3.4 Potential Number of Unsuccessful Harpoon Attempts and Approaches

Under Alternative 2, we estimate that for each whale struck there would be six unsuccessful harpoon attempts, and for each day of hunting there would be 8.3 whales approached. We use the same estimates as used for Alternative 3, although there would be differences between a hunt under Alternatives 2 and 3. Under Alternative 3, the Tribe would most likely use motorized vessels for hunting and would hunt more than 5 miles (8 km) from shore, in contrast to a hunt under Alternative 2, which would involve a wooden canoe and likely be conducted closer to shore, similar to the 1999 and 2000 hunts (Subsection 1.4.2, Summary of Recent Makah Whaling – 1998 through 2022). It may be easier for hunters to successfully approach and strike whales from a motorized vessel than from a canoe, so it is possible that there would be fewer incidents of whales being subjected to unsuccessful harpoon attempts and approaches than estimated for Alternative 2. On the other hand, there could be more approaches under Alternative 3 than Alternative 2 because of the relatively greater ease of getting close to whales in a motorized vessel. Absent specific information about an offshore motorized hunt, and given these considerations, we relied on the same information used under Alternative 2 to estimate the potential number of unsuccessful harpoon attempts and approaches.

Under Alternative 3, with a maximum of six possible strikes per year, there might be 36 unsuccessful harpoon attempts (i.e., using the 6:1 ratio of unsuccessful harpoon attempts to successful strikes from

the combined 1999 and 2000 hunting seasons). Although hunting and scouting would be combined under Alternative 3, approaches of whales would only occur on days with whales present; thus, we use the same number of hunting days to estimate approaches as we used for Alternative 2. With up to 33.2 suitable hunting days per year in the spring (March through May), the potential number of times that tribal hunters might approach a whale would be 276 (8.3 per day times 33.2 days). If tribal members hunted during the winter as well, there could be an additional 77 approaches (8.3 per day times 9.3 days). Some of these unsuccessful harpoon attempts and approaches could be repeated incidents involving the same whale. We also estimated the number of instances in which PCFG, OR-SVI, and Makah U&A whales could be subjected to unsuccessful harpoon attempts or approaches by hunters. For these estimates, we multiplied the number of strikes and approaches times the proportion of each grouping of whales observed in the coastal portion of the Makah U&A during March through May (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). The estimates are displayed in Table 4-6.

Finally, we estimated the likelihood of an unsuccessful harpoon attempt or approach involving a WNP whale. For these estimates we relied on modeling by Moore et al. (2023), as described above (Subsection 4.1.3.3, Potential Number of ENP and PCFG Whales Killed; Likelihood of Striking a WNP Whale; Likely Number of Whales Harvested). These are highly precautionary estimates of the maximum potential impact to WNP gray whales under Alternative 3, for the same reasons as described under Alternative 2 in Subsection 4.1.2.3. The estimates are displayed in Table 4-6.

Table 4-6. Estimated number of strikes, unsuccessful harpoon attempts, and approaches of ENP, PCFG, OR-SVI, Makah U&A (MUA), and WNP whales under Alternative 3.

Whales		Number of Strikes[a]			Number of Unsuccessful Harpoon Attempts[b]			Number of Approaches[c]		
		Annual	**6-year**	**10-year**	**Annual**	**6-year**	**10-year**	**Annual**	**6-year**	**10-year**
ENP[d]		6	36	60	36	216	360	353	2,118	3530
PCFG[e]	27.3%	1.6	9.8	16.4	9.8	59.0	98.3	96.4	578.2	963.7
OR-SVI[e]	26.2%	1.6	9.4	15.7	9.4	56.6	94.3	92.5	554.9	924.9
MUA[e]	23.4%	1.4	8.4	14.0	8.4	50.5	84.2	82.6	495.6	826.0
WNP[f]	0.8-1.2%	0.048-0.072	0.29-0.43	0.48-0.72	0.29-0.43	1.7-2.6	2.9-4.3	2.8-4.2	16.6-25.0	27.7-41.6

a. Limited by regulation.
b. Calculated using number of unsuccessful harpoon attempts per successful strike (6:1), based on experience during 1999 and 2000 hunts combined.
c. Calculated using an estimate of 8.3 approaches per day of hunting, based on experience during the 2000 hunt, and a high estimate of 42.5 suitable hunting days per year.
d. ENP estimates are maximum values.
e. Percentage estimates are based on the springtime whale analysis by Calambokidis et al. (2019) which compares whales seen in the spring to the entire catalog of whales identified in the PCFG range during the summer/fall feeding period (in contrast to the definition we use in this FEIS for PCFG whales, which requires a whale to have been seen in at least 2 years). This results in estimates that are likely higher and therefore more conservative than estimates that would be derived from a comparison with whales observed in at least 2 years. We conclude that this conservative approach is appropriate as it allows for the possibility that a whale sighted in the spring might later be seen for the second time in the PCFG seasonal range. Note that OR-SVI and MUA are nested regions within the PCFG range.
f. Median probability based on modeling by Moore et al. (2023) given an ENP gray whale population abundance range of approximately 11,000 to 16,000 animals.

4.1.3.5 Potential Number of Shots Fired or Grenade Explosions

For the reasons described under Alternative 2, we estimate there would be 16 rifle shots for each harvested whale. This would result in up to 64 rifle shots per year (16 shots times four whales harvested) and up to 384 shots over a 6-year period (64 shots annually times 6 years). If grenades were used in addition to rifles, we estimate there would also be a maximum of three grenade explosions for each whale harvested, as described under Alternative 2. Thus, under Alternative 3, we would expect up to 12 explosions per year if up to four whales are successfully harvested annually (or 72 explosions over a 6-year period). It is possible that rifle shots and grenade explosions could result in behavioral disturbance of nearby whales. Grenade explosions could also cause temporary hearing threshold shifts in gray whales. However, it is unlikely that hunters would fire rifles or grenades at a whale before it has been "made fast" with a harpoon attached to a buoy. As a result, they can largely limit the impacts of gunshots and grenade explosions to the whale being harvested by first separating it from any nearby whales. In addition, effects would be related to the timing and location of the noise relative to the nearby whale's location and activity. Any noise from a gunshot would probably decay to ambient levels within 1 or 2 miles of the source, and the duration of the sound is expected to only last a few seconds. Given this, any disturbance from the use of weapons be temporary, and it is unlikely that these activities will have a discernable impact on the ENP gray whale stock's abundance, rate of growth, or distribution, or that these activities will affect their migration under Alternative 3.

It is also possible there could be shots fired or grenades exploded in conjunction with struck and lost whales, but we consider this unlikely because of the way "harvest" is defined. A whale is considered harvested once a flag or buoy has been attached (essentially, once a harpoon is successfully embedded). It is unlikely that hunters would fire rifles or grenades at a whale before it has been "made fast" with a harpoon attached to a buoy (refer to the Glossary and Subsection 1.1.1, Summary of the Proposed Action).

4.1.4 Alternative 4, Summer/Fall Hunt

Alternative 4 would have the same conditions as Alternative 2 regarding the hunt area (coastal portion of the Tribe's U&A), the hunting methods, and regulatory framework. In contrast to Alternative 2, Alternative 4 would have a different hunting season (June 1 through November 30 instead of December 1 through May 31) designed to completely avoid times when a WNP whale might be present. It would also prohibit striking whales within 200 yards (183 m) of Tatoosh Island and White Rock during any month to minimize disturbance to feeding and nesting seabirds, and would require that hunters approach only known males from the ENP stock (which includes PCFG males) to account for the possible importance of mothers in recruiting offspring to the PCFG via matrilineal site fidelity. Alternative 4 would also

differ from Alternative 2 in the way in which the PCFG limit would be calculated and the way in which struck and lost whales would be counted against the limit (described in more detail below and displayed in Table 4-7). These and additional details are described in Subsection 2.3.4, Alternative 4 (Summer/Fall Hunt).

4.1.4.1 Potential Timing of a Hunt and Number of Hunting Days

Under Alternative 4, the hunting season would be June 1 through November 30—the opposite time of year from the hunting season in Alternatives 2 and 3 (December through May)—and hunting could occur any time during this period.

Under Alternative 2, where hunting would be more likely to occur during the spring, the factors most likely to influence the number of hunting days would be ocean conditions and the availability of whales. In contrast, under Alternative 4, there would be several months with many days of favorable ocean conditions (especially from June through September) (Table 4-2); thus, ocean conditions would not be a limiting factor. Under Alternative 4, the factor most likely to affect the number of hunting days would be the ability of the hunters to locate and strike a known male PCFG whale. As described in Subsection 3.4.3.4.2 (PCFG Seasonal Distribution, Migration, and Movements), the Makah Tribe's marine mammal biologist participates in a collaborative effort to survey gray whales by surveying the Makah U&A throughout the year but primarily during the summer feeding season. The survey involves searching for, approaching, photographing, and/or taking biopsies of whales. The biopsy effort is a reasonable proxy for estimating the likely success of hunters in locating, approaching, and striking a known male (i.e., biopsied and cataloged as a male). According to the Tribe's analysis (J. Scordino, pers. comm., Makah Tribe Marine Mammal Biologist, July 31, 2013) a reasonable estimate of the maximum number of days it would take for tribal hunters to locate and strike a known male is 7 days. We have reviewed this analysis and concur that it is reasonable.

4.1.4.2 Potential Number and Types of Vessels

The hunt under Alternative 4 would involve the same number and types of vessels as the hunt under Alternative 2.

4.1.4.3 Potential Number of ENP and PCFG Whales Killed; Likelihood of Striking a WNP Whale; Likely Number of Whales Harvested

Potential Number of ENP Whales Killed

The potential number of ENP whales killed under Alternative 4 would be determined by the PCFG limit, which would be one based on current abundance estimates and mixing ratios. Any whale struck would be counted as a PCFG whale (Subsection 2.3.4, Alternative 4 (Summer/Fall Hunt)). Table 4-7 illustrates how the PCFG limit would be calculated. Because Alternative 4 (like Alternative 2) would

allow up to seven strikes per year, the number of ENP whales potentially killed could be as high as seven, but this would require the PCFG abundance to more than triple, which is highly unlikely.

Table 4-7. Alternative 4 method of calculating PCFG mortality limits.

Element	Current Value	Source for Establishing Value in Future Calculations[a]	Notes
One-half maximum net productivity rate (Rmax)	(½) 0.062 = 0.031	NMFS' Stock assessment report (Carretta et al. 2023)	See Subsection 3.4.2.1.4, Defining and Calculating PBR
Minimum population abundance of PCFG (Nmin)	227	NMFS' Stock assessment report (Carretta et al. 2023)	See Subsection 3.4.3.4.3, PCFG Abundance and Trends
Recovery factor for PCFG	0.35	Wade (1998)	See Subsection 3.4.2.1.4, Defining and Calculating PBR
Other sources of human-caused mortality	1.7	NMFS' Stock assessment report (Carretta et al. 2023)	See Subsection 3.4.3.4.4 PCFG Status, Carrying Capacity (K), and Related Estimates
CURRENT RESULT	Total Mortality: (0.031) * (227) * 0.35 = 2.46 – 1.7 = **0.76**[b]		

[a] Values for some of the elements used in this calculation are derived from NMFS Stock Assessment Reports, the most recent of which is Carretta et al. (2023), as described under Subsection 2.3.4 Alternative 4 (Summer/Fall Hunt). These values (e.g., for Rmax and Nmin) may change as new information becomes available.

[b] Hunting could not occur when the PCFG mortality limit is less than 1.0 whales. However, when the annual mortality limit is less than 1.0 but greater than 0.5 during 2 consecutive years, the values would be aggregated to allow for the mortality of one PCFG whale during the second year.

Maximum and Likely Number of PCFG, OR-SVI, and Makah U&A Whales Killed

Under Alternative 4, there is a very high likelihood that killed whales would be PCFG males because of the requirement to approach only known males and many of these cataloged males have been seen previously in the PCFG seasonal range. Because the hunt would occur in the Makah U&A in the summer months, any PCFG whale killed would also be an OR-SVI and Makah U&A whale. (If the PCFG abundance increased dramatically in the future, resulting in an increased PCFG mortality limit, any whales killed would likely be PCFG, OR-SVI, and Makah U&A whales for the same reasons.)

Also, unused portions of the PCFG mortality limit would not carry over to a subsequent year, except that when the mortality limit is less than 1 but greater than 0.5 during 2 consecutive years, it would be aggregated to allow for the mortality of one PCFG whale during the second year. The purpose of not allowing mortality limits to carry over is to prevent mortality of multiple PCFG whales in a single year

(unless the calculated mortality limit allowed for more than one whale to be killed[7]). The purpose of allowing a carry-over when the mortality limit is greater than 0.5 but less than 1 is to afford the Tribe an opportunity to hunt at least every other year but with a harvest limit that is sensitive to declines in PCFG abundance or if PCFG whales are killed in unexpected numbers by other sources of human-caused mortality (the current level of human-caused mortality averages about 1.7 whales per year) (Carretta et al. 2023).

No hunting would be permitted when the PCFG mortality limit for a single year is less than 0.5, nor would the mortality limit carry over. The purpose of this provision is to prohibit a hunt if the PCFG experiences a significant decline or if PCFG whales are killed in unexpected numbers by other sources of human-caused mortality.

Likelihood of Striking a WNP Whale

The hunting season under Alternative 4 is designed to avoid the potential for striking a WNP whale. It is extremely unlikely that a WNP whale would be struck under Alternative 4 because such whales would be feeding in the WNP during the summer feeding period.

Likely Number of ENP Whales Harvested

The maximum number of whales the Tribe could harvest based on current information would be one every other year because of the PCFG limit. It is possible that the Tribe would harvest no whales in multiple consecutive years, either because of the difficulty of locating and striking only known males or because, under Alternative 4, a struck and lost whale would count against the PCFG limit, thus ending the hunt for that year. We therefore consider the *likely* harvest under Alternative 4 to be between zero and one whale, with an average of 0.5 whales per year. This represents 0.0034% of the ENP gray whale population, and 0.12%, 0.19%, or 0.38% of PBR (based on the informational estimates of PBR calculated in Subsection 3.4.3.3.4 ENP Status, Carrying Capacity, and Related Estimates). This level of mortality, although higher than under the No-action Alternative, would not be likely to have a discernable effect on the ENP stock's abundance or rate of growth or on the stock's abundance relative to OSP due to the small percentage of the stock that could be affected.

4.1.4.4 Potential Number of Unsuccessful Harpoon Attempts and Approaches

Under Alternative 2, we estimated that for each whale struck there would be six unsuccessful harpoon attempts, and for each day of hunting there would be 8.3 whales approached. It is possible that the ratio of unsuccessful harpoon attempts to successful strikes could be lower under Alternative 4 because whales approached during the summer feeding period may be more likely to be milling and less likely

[7] For example, the mortality limit could reach two whales in a single year if the PCFG minimum population estimate increased to 240 whales and all other calculation values in Table 4-7 remained constant.

to be traveling than whales found during the spring, making them more vulnerable to a successful strike. Nevertheless, for purposes of this analysis, we use the observed ratio of 6:1 for Alternative 4, as this represents the best information available based on actual experience from the 1999 and 2000 hunts. With only one strike under Alternative 4, we would therefore expect six (one strike times six unsuccessful harpoon attempts) unsuccessful harpoon attempts.

With a likelihood of 7 hunting days every other year, the potential number of times that tribal hunters might approach a whale would be 58 (8.3 times per day times 7 days) in those years. Some of these unsuccessful harpoon attempts and approaches might be repeated incidents involving the same whale. We also estimated the number of instances in which PCFG, OR-SVI, and Makah U&A whales might be subjected to unsuccessful harpoon attempts or approaches by hunters. For these estimates, we assumed that any whale subjected to unsuccessful harpoon attempts or approaches by hunters in the coastal portion of the Makah U&A between June 1 and November 30 would be a PCFG whale and, therefore, would also be an OR-SVI and Makah U&A whale. The estimates are displayed in Table 4-8.

Finally, we estimated the likelihood of an unsuccessful harpoon attempt or approach involving a WNP whale. It is extremely unlikely that a WNP whale would be struck under Alternative 4 because such whales would be feeding in the WNP during the summer feeding period. Therefore, we assume the proportion of WNP whales present in the hunt area during the summer hunt months is 0 (Table 4-8).

Table 4-8. Estimated number of strikes, unsuccessful harpoon attempts, and approaches of ENP, PCFG. OR-SVI, Makah U&A, and WNP whales under Alternative 4.

Whales		Number of Strikes[a]			Number of Unsuccessful Harpoon Attempts[b]			Number of Approaches[c]		
		Annual	**6-year**	**10-year**	**Annual**	**6-year**	**10-year**	**Annual**	**6-year**	**10-year**
ENP		0.5	3	5	3	18	30	29	174	290
PCFG[d]	100%	0.5	3	5	3	18	30	29	174	290
OR-SVI[d]	100%	0.5	3	5	3	18	30	29	174	290
MUA[d]	100%	0.5	3	5	3	18	30	29	174	290
WNP[e]	0%	0	0	0	0	0	0	0	0	0

a. Limited by mortality limit for PCFG whales.
b. Calculated using number of unsuccessful harpoon attempts per successful strike (6:1), based on experience during the 1999 and 2000 hunts combined.
c. Calculated using an estimate of 8.3 approaches per day of hunting, based on experience during the 2000 hunt, and a high estimate of 7 hunting days.
d. 100 percent estimates based on requirement to approach only known ENP males, the high likelihood that these would be PCFG whales, and the conservative assumption that any known PCFG male in the Makah U&A during the hunting season is presumed to be a Makah U&A whale. Note that OR-SVI and Makah U&A are nested regions within the PCFG range.
e. Values assumed to be zero because there are no records of WNP whales in the Makah U&A during the June through November timeframe associated with this alternative.

4.1.4.5 Potential Number of Shots Fired or Grenade Explosions

For the reasons described under Alternative 2, we estimate there would be 16 shots fired for each whale harvested. Thus, under Alternative 4, we would expect up to 16 shots fired every other year (16 shots times one whale harvested every other year) and up to 48 shots over a 6-year period. If grenades are used in addition to or instead of a rifle, we estimate there would also be three grenade explosions for each whale harvested. Thus, under Alternative 4 we would expect up to three grenade explosions every other year and up to 9 explosions over a 6-year period.

It is possible that rifle shots and grenade explosions could result in behavioral disturbance of nearby whales. Grenade explosions may also cause temporary hearing threshold shifts in gray whales. However, it is unlikely that hunters would fire rifles or grenades at a whale before it has been "made fast" with a harpoon attached to a buoy. As a result, they can largely limit the impacts of gunshots and grenade explosions to the whale being harvested by first separating it from any nearby whales. In addition, effects would be related to the timing and location of the noise relative to the nearby whale's location and activity. Any noise from a gunshot would probably decay to ambient levels within 1 or 2 miles of the source, and the duration of the sound is expected to only last a few seconds. Given this, any disturbance from the use of weapons be temporary, and it is unlikely that these activities will have a discernable impact on the ENP gray whale stock's abundance, rate of growth, or distribution, or that these activities will affect their migration under Alternative 4.

It is also possible there could be shots fired or grenades exploded in conjunction with struck and lost whales, but we consider this unlikely because of the way "harvest" is defined. A whale is considered harvested once a flag or buoy has been attached (essentially, once a harpoon is successfully embedded). It is unlikely that hunters would fire rifles or grenades at a whale before it has been "made fast" with a harpoon attached to a buoy (refer to the Glossary and Subsection 1.1.1, Summary of the Proposed Action).

4.1.5 Alternative 5, Split-season Hunt

Alternative 5 would have the same conditions as Alternative 2 regarding the hunt area (coastal portion of the Tribe's U&A), hunting methods, and regulatory conditions. In contrast to Alternative 2, Alternative 5 would have a different "split-season" hunting period (December 1 through December 21 and May 10 through May 31, instead of December 1 through May 31). Alternative 5 would also differ from Alternative 2 in the way in which the PCFG limit would be calculated and the way in which struck and lost whales would be counted against the limit (described in more detail below and displayed in Table 4-9). These and additional details are described in Subsection 2.3.5, Alternative 5 (Split-Season Hunt).

4.1.5.1 Potential Timing of a Hunt and Number of Hunting Days

Under Alternative 5, the hunting season would be 3 weeks in December and 3 weeks in May, in contrast to Alternative 2 which has a 6-month-long hunting season. As described under Alternative 2, factors most likely to affect the timing of a hunt and number of hunting days would be ocean conditions and presence of whales (Subsection 4.1.2.1, Potential Timing of a Hunt and Number of Hunting Days).

The hunting seasons under Alternative 5 would be December 1 through 21 and May 10 through 31. Similar to Alternative 2, we expect that tribal members under Alternative 5 would only hunt in favorable ocean conditions when whales have been detected in the hunt area. In contrast to Alternative 2, we focused our review of data for wind speed and wave height in the hunt area for just the periods of December 1 through 21 and May 10 through 31 and concluded that the proportion of days with favorable ocean conditions was 22.5 percent for December and 78.0 percent for May (NOAA National Data Buoy Center 2013). Using those proportions (instead of the monthly values in Table 4-2 used for Alternative 2) yields 4.7 days of favorable ocean conditions in December (21 days times 0.225 = 4.7) and 17.2 days of favorable ocean conditions in May (22 days times 0.780 = 17.2).

As under Alternative 2, we expect that hunting under Alternative 5 would only occur on days with favorable ocean conditions and whales present in the hunt area. Applying the proportion of days that whales are present from Table 4-2 yields 3.5 days of favorable ocean conditions and whales present for December 1 through 21 (4.7 days times 0.75 = 3.5) and 11.2 days of favorable ocean conditions and whales present for May 10 through 31 (17.2 days times 0.65 = 11.2) for a total of 14.7 hunting days per year. Also, as with Alternative 2, we expect hunting would be most likely to occur in the spring (May) however, we also consider the potential impacts of a winter hunt because it is possible that tribal members might hunt in December.

Under Alternative 5, there may also be days in which tribal members scout for whales using a motorized vessel. As with Alternative 2, we assume scouting may occur on every day with favorable ocean conditions. During May 10 through 31, as described above, there are a total of 17.2 days with favorable ocean conditions; thus, we assume there could be 17.2 days of scouting and training effort during May, which is the most likely time for hunting to occur. If tribal members chose to hunt during December as well, there could be an additional 4.7 days with favorable ocean conditions, for a total of 22 possible days of hunt-related trips (including scouting and training effort) under Alternative 5.

To summarize, we expect days of hunting and scouting[8] to occur under Alternative 5 as follows:

[8] Some scouting days could result in hunting days if a whale is located by scouts and then hunted.

- Most likely: May 10 through 31
  - 17.2 scouting and training days, 11.2 hunting and training days
- Less likely: December 1 through 21
  - 4.7 scouting and training days, 3.5 hunting and training days

4.1.5.2 Potential Number and Type of Vessels

The hunt under Alternative 5 would involve the same number and types of vessels as the hunt under Alternative 2.

4.1.5.3 Potential Number of ENP and PCFG Whales Killed; Likelihood of Striking a WNP Whale; Likely Number of Whales Harvested

Potential Number of ENP Whales Killed

Alternative 2, the Tribe's proposal, would include a regulatory limit of seven strikes per year, which would limit the number of whales killed per year to seven. In contrast, Alternative 5 does not include a strike limit, but the mortality limit for PCFG whales in concert with the IWC limit on total catches would effectively limit the number of strikes per year, and thus, limiting the number of whales killed to four per year, on average, with a maximum of five in a single year. This maximum number would be reached in only three scenarios: (1) if the Tribe harvested the annual maximum (under the IWC catch limit) of 5 non-PCFG whales, (2) if the Tribe harvested four non-PCFG whales and then harvested a PCFG whale, or (3) if the Tribe harvested four non-PCFG whales and then struck and lost a fifth whale (assumed to have subsequently died). A total mortality of up to 5 whales in a given year (assuming all struck and lost whales die) represents 0.034 percent of the current ENP gray whale population abundance (estimated to be 14,526 whales) and 1.2 or 2.4 percent of PBR (based on the informational estimates of PBR calculated in Subsection 3.4.3.3.4 ENP Status, Carrying Capacity, and Related Estimates). This level of mortality, although higher than under the No-action Alternative, would not be likely to have a discernable effect on the ENP stock's abundance or rate of growth or on the stock's abundance relative to OSP due to the small percentage of the stock that could be affected.

Maximum and Likely Number of PCFG, OR-SVI, and Makah U&A Whales Killed

Some of the whales killed under Alternative 5 might be PCFG whales, and of those, some might also be OR-SVI and Makah U&A whales. Under Alternative 5, a mortality limit would be set on PCFG whales equivalent to 10 percent of PBR as reported in NMFS' most recent stock assessment report (Subsection 3.4.2.1.4, Defining and Calculating PBR). Table 4-9 illustrates how the limit would be calculated. Under current conditions, the PCFG mortality limit would be 0.35 whales. Because this limit represents less than one whale, it would differ from the mortality limits in other alternatives in

that it would be allowed to accumulate across years for the purposes of calculating how frequently a PCFG whale could be killed or struck and lost. Although this PCFG mortality limit would always be less than one whale, the Tribe could hunt in any year—including the first year—until they either (1) kill a PCFG whale or (2) strike and lose any whale. If either of those two outcomes occur, the PCFG mortality limit would be applied to determine the number of years during which the Tribe would need to take a hiatus from hunting (i.e., until the accumulated mortality limits would add up to at least one whale).

For example, if the Tribe killed a PCFG whale in the first year of hunting, the PCFG mortality limit would be reduced to zero, and there would be a hiatus until mortality limit calculations had accumulated (over subsequent years) to yield a value greater than or equal to one whale. In this example, and using current calculated values, the Tribe could not hunt again until year 4, because it would take 3 years for a PCFG mortality limit of 0.35 whales to reach at least one whale (i.e., 0.35 whales/year times 3 years = 1.05 whales).

Alternatively, if the Tribe strikes and loses any whale in the first year of hunting then the PCFG mortality limit would be reduced from one whale by a fraction equal to the proportional presence of PCFG whales in the coastal portion of the Makah U&A during the season in which it was struck (e.g., 0.27 whales in the spring when the Tribe is most likely to hunt). As a result, if a whale is struck and lost during the spring, then the PCFG mortality limit would be reduced to 0.73 whales (1 whale minus 0.27 whales), and hunting would cease until the next year, when the mortality limit calculations had accumulated to yield a value greater than or equal to one whale (i.e., 0.73 whales plus 0.35 whales in year 2 = 1.08 whales). And if the Tribe strikes and loses a whale in year 2, then hunting would cease until year 3, and so on (i.e., hunting could occur every year under this continued struck-and-lost scenario).

In the case of either a killed or a struck-and-lost whale and if new information which changes the PCFG mortality limit (such as a change in the minimum population size estimate) became available during the hiatus period, it could affect the length of that hiatus. For example, in the scenario above for a killed whale, if the PCFG mortality limit was 0.35 whales in the year of the kill but increased to 0.5 in subsequent years, then the Tribe would only need to take a 1-year hiatus from hunting (i.e., 0.5 whales/year times 2 years = 1 whale at the start of year 3).

Table 4-9. Alternative 5 method of calculating PCFG mortality limits.

Element	Current Value	Source for Establishing Value in Future Calculations[a]	Notes

One-half maximum net productivity rate (Rmax)	(½) 0.062 = 0.031	NMFS' Stock assessment report (Carretta et al. 2023)	See Subsection 3.4.2.1.4, Defining and Calculating PBR
Minimum population abundance of PCFG (Nmin)	227	NMFS' Stock assessment report (Carretta et al. 2023)	See Subsection 3.4.3.4.3, PCFG Abundance and Trends
Recovery factor for PCFG	0.5	NMFS' stock assessment report (Carretta et al. 2023)	See Subsection 3.4.2.1.4, Defining and Calculating PBR
CURRENT RESULT	Total Mortality: (0.031) * (227) * 0.5 = 3.3 * 0.10 = **0.35**		

[a] Values for the elements used in this calculation are derived from NMFS Stock Assessment Reports, the most recent of which is Carretta et al. (2023), as described in Subsection 2.3.5 Alternative 5 (Split-season Hunt). These values may change as new information becomes available.

Using the struck and lost example above and assuming that every struck-and-lost whale was a PCFG whale that died, then the *maximum* number of PCFG whales that might be killed under Alternative 5 would be approximately one whale per year. However, it is unlikely that would actually be the case given the proportion of PCFG whales present in the Makah U&A during the spring portion of the hunting season when the Tribe is most likely to hunt (Table 4-10). Taking into account that spring proportion yields a more *likely* estimate of one PCFG whale struck and lost (and dies) every 4 years.[9] If the Tribe also hunted in the winter, it is uncertain what the proportion of PCFG whales would be; thus, there could be more or fewer whales killed (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements).

Likelihood of Striking a WNP Whale

The split hunting season under Alternative 5 is designed to avoid the potential for striking a WNP whale during times that are outside the June through November season that defines the PCFG. However, there are very limited data for WNP whales in the action area to inform this analysis (Subsection 3.4.3.2.2, WNP Seasonal Distribution, Migration, and Movements). Therefore, we calculated the likelihood of a Makah hunt striking (killing) a WNP gray whale (Table 4-10) using the estimates derived from modeling by Moore et al. (2023) based on the best data available. These are highly precautionary estimates of the maximum potential impact to WNP gray whales under Alternative 5, for the same reasons as described under Alternative 2 in Subsection 4.1.2.3.

[9] This is estimated by dividing one "successful" strike on a PCFG whale by the 27.3 percent chance of that strike actually being on a PCFG whale, which yields 3.7 strike attempts (rounded to 4 strike attempts). Because hunting could occur every year under a struck-and-lost scenario, it would take 4 years to make 4 strike attempts and achieve the expected strike of one PCFG whale.

Likely Number of ENP Whales Harvested

For a variety of reasons, it is extremely unlikely the Tribe would harvest an average of four whales per year over 6 years under Alternative 5. As described above in this subsection, the limit on PCFG whales under current conditions would be 0.35 per year, or one PCFG whale every 3 years. Given that the proportion of PCFG whales present in the coastal portion of the Makah U&A during the spring hunting season is 27.3 percent, the chances are that one out of about every four whales struck would be a PCFG whale. If the Tribe harvested a PCFG whale, there would be a 2-year hiatus for the PCFG mortality limit to re-set at one whale, based on current information. If the Tribe struck and lost a whale, it would count as 0.27 of a PCFG whale, and hunting would cease until the following year.

In addition to the constraints imposed by the PCFG mortality limit, the hunting season of 22 days in May would make it difficult for the Tribe to harvest more than one whale. For these reasons, we assume under Alternative 5 that if the Tribe successfully harvested a non-PCFG whale it would end the hunt for that year rather than risk killing a PCFG whale; thus, one would likely be the maximum number of whales harvested in a year. Given that one PCFG whale would likely be struck every fourth attempt (and the condition that killing a PCFG whale would invoke a 2-year hiatus under current conditions), the Tribe might harvest a whale in 4 out of 6 years if it did not strike and lose any whales. For Alternative 5, we therefore assume the harvest might be zero to one whale per year under current conditions.

4.1.5.4 Potential Number of Unsuccessful Harpoon Attempts and Approaches

Under Alternative 2, we estimate that for each whale struck there would be six unsuccessful harpoon attempts, and for each day of hunting there would be 8.3 whales approached. A hunt under Alternative 5 would occur in the same area, within a subset of the same time period, and using the same methods as the hunt under Alternative 2. We therefore apply the same assumptions to a hunt under Alternative 5 as under Alternative 2 regarding the number of unsuccessful harpoon attempts per successful strike, and the number of whales approached per day of hunting (Subsection 4.1.2.4, Potential Number of Unsuccessful Harpoon Attempts and Approaches).

Under Alternative 5, with a maximum of five strikes annually (and an average of four per year over 6 years), there might be 24 unsuccessful harpoon attempts (four strikes times six unsuccessful harpoon attempts). With a potential for up to 14.7 hunting days per year, the potential number of times that tribal hunters might approach a whale would be 122 (8.3 whales per day times 14.7 days). Some of these attempted strikes and approaches could be repeated incidents involving the same whale. We also estimated the number of instances in which PCFG, OR-SVI, and Makah U&A whales could be subjected to unsuccessful harpoon attempts or approaches by hunters. Under Alternative 5, there would

be an annual PCFG mortality limit—currently calculated at 0.35 whales. Given the struck and lost accounting described above (which factors in the proportional presence of PCFG whales and estimates one being struck every 5 years), we estimate 0.25 annual strikes on PCFG whales and use this value to estimate the number of unsuccessful harpoon attempts. The number of approaches on PCFG whales also takes into account the proportional presence of PCFG whales. Related approach and attempted strike estimates for OR-SVI and Makah U&A whales are based on the proportion of each subgroup of whales previously observed in the coastal portion of the Makah U&A during March through May (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). The estimates are displayed in Table 4-10.

Finally, we estimate the likelihood of an unsuccessful harpoon attempt or approach involving a WNP whale. For these estimates, we relied on modeling by Moore et al. (2023), as described above (Subsection 4.1.5.3, Potential Number of ENP and PCFG Whales Killed; Likelihood of Striking a WNP Whale; Likely Number of Whales Harvested). These are highly precautionary estimates of the maximum potential impact to WNP gray whales under Alternative 5, for the same reasons as described under Alternative 2 in Subsection 4.1.2.3. The estimates are displayed in Table 4-10.

Table 4-10. Estimated number of strikes, unsuccessful harpoon attempts, and approaches of ENP, PCFG, OR-SVI, Makah U&A, and WNP whales under Alternative 5.

Whales		Number of Strikes			Number of Unsuccessful Harpoon Attempts[b]			Number of Approaches[c]		
		Annual	6-year	10-year	Annual	6-year	10-year	Annual	6-year	10-year
ENP		5[a]	24[a]	40	30	144	240	122	732	1220
PCFG[d]	27.3%	0.25[e]	1.5	2.5	1.5	9.0	15.0	33.3	199.8	333.1
OR-SVI[d]	26.2%	0.24[f]	1.4	2.4	1.4	8.6	14.3	32.0	191.8	319.6
MUA[d]	23.4%	0.21[g]	1.2	2.1	1.2	7.5	12.5	28.5	171.3	285.5
WNP[h]	0.8-1.2%	0.040-0.060	0.19-0.29	0.32-0.48	0.24-0.36	1.2-1.7	1.9-2.9	0.98-1.5	5.9-8.8	9.8-14.6

a. Limited by regulation and by the PCFG mortality limit and method of accounting for struck and lost whales as PCFG whales (five would be the maximum in any one year and no more than 24 could be struck over 6 years).
b. Calculated using number of unsuccessful harpoon attempts per successful strike (6:1), based on experience during 1999 and 2000 hunts combined.
c. Calculated using an estimate of 8.3 approaches per day of hunting and a high estimate of 14.7 hunting days (11.2 days in May plus 3.5 days in December).
d. Percentage estimates are based on the springtime whale analysis by Calambokidis et al. (2023) which compares whales seen in the spring to the entire catalog of whales identified in the PCFG range during the summer/fall feeding period (in contrast to the definition we use in this FEIS for PCFG whales, which requires a whale to be have been seen in at least 2 years). This approach results in estimates that are likely higher and, therefore, more conservative than estimates derived from a comparison with whales observed in at least 2 years. We conclude this conservative approach is appropriate as it allows for the possibility that a whale sighted in the spring might later be seen for the second time in the PCFG seasonal range. Note that OR-SVI and MUA are nested regions within the PCFG range.
e. Hunting would be managed so that the average annual mortality of PCFG whales would not exceed 10 percent of PBR (currently 0.35 whales per year). The values shown are based on the proportion of PCFG whales in the MUA during the spring and the estimate that one PCFG whale is struck every 5 years.
f. Based on the proportional presence (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements), 95 percent of PCFG whales in the MUA during March through May are also OR-SVI whales (0.259 divided by 0.273 = 0.95, and 0.95 times 0.25 = 0.24).
g. Based on the proportional presence (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements), 83 percent of PCFG whales in the MUA during March through May are also MUA whales (0.2254 divided by 0.273 = 0.83, and 0.83 times 0.25 = 0.21).
h. Median probability based on modeling by Moore et al. (2023) given an ENP gray whale population abundance range of approximately 11,000 to 16,000 animals.

4.1.5.5 Potential Number of Shots Fired or Grenade Explosions

For the reasons described under Alternative 2, we estimate there would be 16 rifle shots fired for each whale harvested. Thus, under Alternative 5, we would expect up to 16 shots fired per year (16 shots times one whale harvested) and up to 96 shots over a 6-year period. If grenades are used instead of or in addition to a rifle, as described under Alternative 2, we estimate there would be three grenade explosions for each whale harvested. Thus, under Alternative 5, we would expect up to three grenade explosions per year and up to 18 explosions over a 6-year period.

It is possible that rifle shots and grenade explosions could result in behavioral disturbance of nearby whales. Grenade explosions may also cause temporary hearing threshold shifts in gray whales. However, it is unlikely that hunters would fire rifles or grenades at a whale before it has been "made fast" with a harpoon attached to a buoy. As a result, they can largely limit the impacts of gunshots and grenade explosions to the whale being harvested by first separating it from any nearby whales. In addition, effects would be related to the timing and location of the noise relative to the nearby whale's location and activity. Any noise from a gunshot would probably decay to ambient levels within 1 or 2 miles of the source, and the duration of the sound is expected to only last a few seconds. Given this, any disturbance from the use of weapons be temporary, and it is unlikely that these activities will have a discernable impact on the ENP gray whale stock's abundance, rate of growth, or distribution, or that these activities will affect their migration under Alternative 5.

It is also possible there could be shots fired or grenades exploded in conjunction with struck and lost whales, but we consider this unlikely because of the way "harvest" is defined. A whale is considered harvested once a flag or buoy has been attached (essentially, once a harpoon is successfully embedded). It is unlikely that hunters would fire rifles or grenades at a whale before it has been "made fast" with a harpoon attached to a buoy (refer to the Glossary and Subsection 1.1.1, Summary of the Proposed Action).

4.1.6 Alternative 6, Different Limits on Strikes and PCFG, and Limited Duration of Regulations and Permits

Alternative 6 would have the same conditions as Alternative 2 regarding the hunt area (coastal portion of the Tribe's U&A), hunting season (December 1 through May 31) and hunting methods. In contrast to Alternative 2, Alternative 6 would have different limits on strikes. Under Alternative 2, there would be a limit of seven strikes per year, while under Alternative 6 there would be a limit of 7 strikes over a 2-year period, or 3.5 strikes per year on average. Alternative 6 would also differ from Alternative 2 in the way in which the PCFG mortality limit would be calculated and the way in which struck-and-lost whales would be counted against the mortality limit (described in more detail below and displayed in Table 4-11). Finally,

Alternative 6 would differ from Alternative 2 in the regulatory regime adopted, in particular that permits would be issued for a shorter term (3 years instead of 5) and the waiver of the take moratorium and implementing regulations that would last only 10 years whereas the waiver and regulations under Alternatives 2 through 5 would last in perpetuity. These and additional details are described in Subsection 2.3.6, Alternative 6 (Different Limits on Strikes and PCFG, and Limited Duration of Regulations and Permits). It is not possible to determine whether a new waiver and regulations would be implemented after the waiver under Alternative 6 expired, or what such a waiver and regulations would allow. However, it is possible that Alternatives 2 through 5 could result in a far greater number of strikes, unsuccessful harpoon throws, and approaches over time than Alternative 6 due to the lack of expiration of the waiver period. Because of the uncertainty around the events following the expiration of the waiver period under Alternative 6, for the purposes of this analysis, we examine and compare alternatives in the subsequent sections over a 10-year period.

4.1.6.1 Potential Timing of a Hunt and Number of Hunting Days

Under Alternative 6, the hunting season would be the same as under Alternatives 2 and 3 (December 1 through May 31). Also under Alternative 6, the hunt area would be the same as under Alternative 2 (anywhere in the coastal portion of the Tribe's U&A) and the hunt methods would be the same as under Alternative 2 (use of a wooden canoe and motorized chase vessels).

Because Alternative 6 would have the same conditions as Alternative 2 regarding the hunt area, season, and methods as Alternative 2, we assume there would be the same number of hunting, scouting and training days under Alternative 6 as under Alternative 2. Together, these amount to 60 possible days of hunt-related trips (including scouting and training effort) from December through May. For the reasons described under Alternative 2, this number may be an overestimate. To summarize, we expect days of combined scouting, training, and hunting under Alternative 3 to occur as follows:

- Most likely: March through May
    - 43.3 scouting and training days, 33.2 hunting and training days
- Less likely: December through February
    - 17.1 scouting and training days, 9.3 hunting and training days

4.1.6.2 Potential Number and Types of Vessels

The hunt under Alternative 6 would involve the same number and types of vessels as the hunt under Alternative 2.

4.1.6.3 Potential Number of ENP and PCFG Whales Killed; Likelihood of Striking a WNP Whale; Likely Number of Whales Harvested

Potential Number of ENP Whales Killed

Under Alternative 6, the maximum number of whales that could be killed per year by the Tribe would be determined by the total limit on strikes, which would be no more than four in a single year and seven over 2 years (or 3.5 per year on average). Thus, the maximum number of whales that could be killed would be four in a single year, seven over 2 years, and 3.5 per year on average. This level of mortality represents 0.024 percent of the current ENP gray whale population abundance (estimated to be 14,526 whales) and 0.85 percent or 1.7 percent of PBR (based on the informational estimates of PBR calculated in Subsection 3.4.3.3.4 ENP Status, Carrying Capacity, and Related Estimates). Although higher than under the No-action Alternative, this level of hunt-related mortality would not be likely to have a discernable effect on the ENP stock's abundance or rate of growth or on the stock's abundance relative to OSP due to the small percentage of the stock that could be affected.

Maximum and Likely Number of PCFG, OR-SVI, and Makah U&A Whales Killed

Some of the whales killed might be PCFG whales, and, of those, some might be OR-SVI and Makah U&A whales. Under Alternative 6, a limit would be set on PCFG mortality equal to NMFS' calculation of PBR in its most recent stock assessment report (Subsection 3.4.2.1.4, Defining and Calculating PBR) minus other sources of human-caused mortality. Table 4-11 illustrates how the limit would be calculated. The mortality limits using the current values for the PBR formula and current levels of human-caused mortality as reported in the most recent NMFS stock assessment report (Carretta et al. 2023) would be 1.0 whales total. Because the mortality limit would be set each year, fractions of whales or unused whales would not be carried over to a subsequent year.

Table 4-11. Alternative 6 method of calculating PCFG mortality limits.

Element	Current Value	Source for Establishing Value in Future Calculations[a]	Notes
One-half maximum net productivity rate (Rmax)	(½) 0.062 = 0.031	NMFS' Stock assessment report (Carretta et al. 2023)	See Subsection 3.4.2.1.4, Defining and Calculating PBR
Minimum population abundance of PCFG (Nmin)	227	NMFS' Stock assessment report (Carretta et al. 2023)	See Subsection 3.4.3.4.3, PCFG Abundance and Trends
Recovery factor for PCFG	0.5	NMFS' stock assessment report (Carretta et al. 2023)	See Subsection 3.4.2.1.4, Defining and Calculating PBR
Other sources of human-caused mortality	1.7	NMFS' Stock assessment report (Carretta et al. 2023)	See Subsection 3.4.3.4.4 PCFG Status, Carrying Capacity (K), and Related Estimates
CURRENT RESULT	Total Mortality: (0.031) * (227) * 0.5 = 3.52– 1.7 = **1.82 (Rounded down to 1.0)**		

[a] Values for the elements used in this calculation are derived from NMFS Stock Assessment Reports, the most recent of which is Carretta et al. (2023), as described in Subsection 2.3.6 Alternative 6 (Different Limits on Strike and PCFG, and Limited Duration of Regulations and Permits). These values may change as new information becomes available.

Under Alternative 6, the limit on the maximum number of PCFG whales killed would be equal to the overall strike limit. While 3.5 would, on average, be the *maximum* number of PCFG whales that might be killed each year under Alternative 6, it is unlikely that many would actually be killed given the proportion of PCFG whales present in the Makah U&A during the spring portion of the hunting season, when the Tribe is most likely to hunt. The proportion of PCFG whales in the Makah U&A during the winter portion of the hunting season is unknown. This analysis therefore also considers the *likely* number of PCFG whales that might be killed per year, if the full number of strikes were to occur during the spring. The calculation is based on the proportional presence of PCFG whales in the coastal portion of the Makah U&A during the likely timing of a Makah hunt (March through May). In addition, the analysis considers the likely number of OR-SVI and Makah U&A whales that might be killed in a tribal hunt, if the full number of strikes were to occur during the spring portion of the hunting season.

During the period 1996 to 2016, 27.3 percent of whales identified from March through May in the northern Washington coast survey area were PCFG whales, 26.2 percent were also OR-SVI whales, and 23.4 percent were also Makah U&A whales (Subsection 3.4.3.4.3, PCFG Abundance and Trends). If an average of 3.5 whales were killed per year under Alternative 6, the likely number of PCFG whales

that would be killed would be 0.96 (an average of 3.5 whales killed times 27.3 percent), the likely number of OR-SVI whales killed would be 0.92 (an average of 3.5 whales killed times 26.2 percent), and the likely number of Makah U&A whales killed would be 0.82 (an average of 3.5 whales killed times 23.4 percent). These numbers are subsets of one another (the OR-SVI is contained in the PCFG area and the Makah U&A is contained in the OR-SVI area) (Figure 3-10) so are not additive. These estimates are also displayed in Table 4-12.

If the Tribe also hunted in the winter, it is uncertain what the proportion of PCFG whales would be; thus, there could be more or fewer PCFG, OR-SVI, or Makah U&A whales killed. However, because all struck and lost whales would be counted against the PCFG limit, the average maximum number of PCFG whales that could be killed per year would be 3.5, as described above.

Likelihood of Striking a WNP Whale

We calculated the likelihood of a Makah hunt striking (killing) a WNP gray whale based on 3.5 strikes per year during the spring and using the analysis from Moore et al. (2023) described above under Alternative 2. These are highly precautionary estimates of the maximum potential impact to WNP gray whales under Alternative 6, for the same reasons as described under Alternative 2 in Subsection 4.1.2.3. Table 4-12 shows the probability of a WNP whale being struck.

Likely Number of ENP Whales Harvested

Under Alternative 6, the limit of seven strikes over 2 years would limit the maximum number of whales harvested to seven over 2 years, or 3.5 per year on average.

4.1.6.4 Potential Number of Unsuccessful Harpoon Attempts and Approaches

Under Alternative 2, we estimate that for each whale struck there would be six unsuccessful harpoon attempts, and for each day of hunting there would be 8.3 whales approached. A hunt under Alternative 6 would occur in the same area, within the same time period, and using the same methods as the hunt under Alternative 2. We therefore apply the same assumptions to a hunt under Alternative 6 as under Alternative 2.

Under Alternative 6, with a maximum average of 3.5 strikes per year, there might be 21 unsuccessful harpoon attempts (3.5 strikes times six unsuccessful harpoon attempts). With up to 33.2 hunting days per year in the spring, the potential number of times that tribal hunters might approach a whale would be 276 (8.3 per day times 33.2 days). If tribal members hunted during the winter as well, there could be an additional 77 approaches (8.3 per day times 9.3 days) for a total of 353 approaches per year. Some of these attempted strikes and approaches could be repeated incidents involving the same whale. We also estimate the number of instances in which PCFG, OR-SVI, and Makah U&A whales could be

subjected to unsuccessful harpoon attempts or approaches by hunters. For these estimates, we multiplied the number of strikes and approaches times the proportion of each subgroup of whales observed in the coastal portion of the Makah U&A during March through May (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). The estimates are displayed in Table 4-12.

Finally, we estimate the likelihood of an unsuccessful harpoon attempt or approach involving a WNP gray whale. For these estimates we relied on modeling by Moore et al. (2023), as described above (Subsection 4.1.6.3, Potential Number of ENP and PCFG Whales Killed; Likelihood of Striking a WNP Whale; Likely Number of Whales Harvested). These are highly precautionary estimates of the maximum potential impact to WNP gray whales under Alternative 6, for the same reasons as described under Alternative 2 in Subsection 4.1.2.3. The estimates are displayed in Table 4-12.

Table 4-12. Estimated numbers of strikes, unsuccessful harpoon attempts, and approaches of ENP, PCFG, OR-SVI, Makah U&A, and WNP whales under Alternative 6.

Whales		Number of Strikes[a]			Number of Unsuccessful Harpoon Attempts[b]			Number of Approaches[c]		
		Annual	**6-year**	**10-year**	**Annual**	**6-year**	**10-year**	**Annual**	**6-year**	**10-year**
ENP		3.5	21	35	21	126	210	353	2,118	3530
PCFG	27.3%[d]	0.96	5.7	9.6	5.7	34.4	57.3	96.4	578.2	963.7
OR-SVI	26.2%[d]	0.92	5.5	9.2	5.5	33.0	55.0	92.5	554.9	924.9
MUA	23.4%[d]	0.82	4.9	8.2	4.9	29.5	49.1	82.6	495.6	826.0
WNP[e]	0.8-1.2%	0.028-0.042	0.17-0.25	0.28-0.42	0.17-0.25	1.0-1.5	1.7-2.5	2.8-4.2	16.6-25.0	27.7-41.6

a. Limited by regulation.
b. Calculated using the number of unsuccessful harpoon attempts per successful strike (6:1), based on experience during the 1999 and 2000 hunts combined.
c. Calculated using an estimate of 8.3 approaches per day of hunting and a total of 42.5 hunting days per year.
d. Percentage estimates are based on the springtime whale analysis by Calambokidis et al. (2023) which compares whales seen in the spring to the entire catalog of whales identified in the PCFG range during the summer/fall feeding period (in contrast to the definition we use in this FEIS for PCFG whales, which requires a whale to be have been seen in at least 2 years). This results in estimates that are likely higher and therefore more conservative than estimates that would be derived from a comparison with whales observed in at least 2 years. We conclude that this conservative approach is appropriate as it allows for the possibility that a whale sighted in the spring might later be seen for the second time in the PCFG seasonal range. Note that OR-SVI and Makah U&A are nested regions within the PCFG range.
e. Median probability based on modeling by Moore et al. (2023) given an ENP gray whale population abundance range of approximately 11,000 to 16,000 animals.

4.1.6.5 Potential Number of Shots Fired or Grenade Explosions

For the reasons described under Alternative 2, we estimate there would be 16 shots fired for each whale harvested. Thus, under Alternative 6 we would expect up to 56 shots fired per year on average (16 shots times 3.5 whales harvested on average) and up to 336 shots over a 6-year period. If grenades are used in addition to or instead of a rifle, as described under Alternative 2, we estimate there would be three grenade explosions for each whale harvested. Thus, under Alternative 6 we would expect up to 10.5 (rounded up to 11) grenade explosions per year and up to 63 explosions over a 6-year period.

It is possible that rifle shots and grenade explosions could result in behavioral disturbance of nearby whales. Grenade explosions may also cause temporary hearing threshold shifts in gray whales. However, it is unlikely that hunters would fire rifles or grenades at a whale before it has been "made fast" with a harpoon attached to a buoy. As a result, they can largely limit the impacts of gunshots and grenade explosions to the whale being harvested by first separating it from any nearby whales. In addition, effects would be related to the timing and location of the noise relative to the nearby whale's location and activity. Any noise from a gunshot would probably decay to ambient levels within 1 or 2 miles of the source, and the duration of the sound is expected to only last a few seconds. Given this, any disturbance from the use of weapons be temporary, and it is unlikely that these activities will have a discernable impact on the ENP gray whale stock's abundance, rate of growth, or distribution, or that these activities will affect their migration under Alternative 6.

It is also possible there could be shots fired or grenades exploded in conjunction with struck and lost whales, but we consider this unlikely because of the way "harvest" is defined. A whale is considered harvested once a flag or buoy has been attached (essentially, once a harpoon is successfully embedded). It is unlikely that hunters would fire rifles or grenades at a whale before it has been "made fast" with a harpoon attached to a buoy (refer to the Glossary and Subsection 1.1.1, Summary of the Proposed Action).

4.1.7 Alternative 7, Composite Alternative—Preferred

Alternative 7 is made up of various components from action alternatives 2 through 6. There are two aspects of this composite alternative that differ from the other action alternatives:

(1) It relies on an alternating-year hunt schedule whereby winter/spring hunts would begin in December of the same calendar year that summer/fall hunts occur, and summer/fall hunts would begin in the next calendar year following the end of a winter/spring hunt. The result is that there is a 1-month gap (November) between the end of a summer/fall hunt and the start of a winter/spring hunt and then a 13-month gap between the end of a winter/spring hunt and the

start of the next summer/fall hunt, and so on. Therefore, there would be up to five winter/spring hunts and five summer/fall hunts over the 10-year waiver period.

(2) It is evaluated both (a) with and without low abundance thresholds for ENP gray whales, and (b) with a static low abundance threshold for the PCFG, below which hunting would cease. For our analysis, we have considered four potential scenarios: no low abundance threshold for the ENP stock, a threshold of 11,000 whales, a threshold of 16,000 whales, and a threshold of 18,000 whales. The thresholds are analyzed as Alternatives 7(a), 7(b), and 7(c), respectively. If an ENP abundance threshold is implemented and a cease-hunt were triggered by that threshold, hunting could resume once the ENP population abundance estimate increased above the selected threshold. For the PCFG, we proposed two thresholds in tandem with one another. They consist of a population abundance estimate of 192 whales and a minimum population abundance estimate of 171 whales. If either of these thresholds were triggered, hunting would cease until both estimates increased above their respective thresholds.

Under Alternative 7, in order to conduct hunting, scouting, and training activities in the winter/spring months, the Tribe would need to obtain authorization for the potential incidental take of WNP gray whales (due to the chance of taking such a whale by harassment during winter/spring hunts). If they do not obtain an incidental take authorization (ITA) for WNP gray whales, they would only be authorized to hunt and train in the summer/fall months. This could also happen if the Tribe were to obtain such authorization and subsequently struck a WNP gray whale during a winter/spring hunt (a highly unlikely event that would cause such hunts to cease). For our analysis, we assume that the Tribe will either receive ITSs for hunting in all five winter/spring hunt seasons during the waiver period or that they will not receive permits for winter/spring hunts for the entirety of the 10-year waiver period, in which case only five summer/fall hunts would take place. It is, however, possible that the Tribe could receive permits for some of the winter/spring hunt years but not others, in which case the effects of this alternative would fall between the two scenarios considered.

Under Alternative 7, the Tribe would utilize the same hunt area and overlap with the same winter/spring hunting seasons (i.e., all or portions of the December 1 through May 31 time period) in alternating years as Alternative 2. Like Alternatives 3 through 6, Alternative 7 also includes provisions to limit the number of struck and lost whales and measures to count struck and lost whales against PCFG mortality limits. Alternative 7 also incorporates a similar, but shorter, summer/fall hunting season in alternating years to that described under Alternative 4. This split-season hunt design was first proposed under Alternative 5 to limit the likelihood that tribal hunters would strike or otherwise harm a WNP gray whale during the winter/spring migration period. However, it has been modified under

Alternative 7 to further limit potential impacts on WNP whales by restricting hunts to the summer/fall season every other year to avoid the WNP gray whale migration period. Finally, Alternative 7 incorporates the 10-year waiver period and shorter-duration permits that were proposed as additional precautionary measures under Alternative 6. Much like Alternative 6, it is not possible to determine whether a new waiver and regulations would be implemented after the waiver under Alternative 7 expired, or what such a waiver and regulations would allow. However, it is possible that Alternatives 2 through 5 could result in a far greater number of strikes, unsuccessful harpoon throws, and approaches over time than Alternatives 6 and 7 due to the lack of expiration of the waiver period. Because of the uncertainty around the events following the expiration of the waiver period under Alternative 7, for the purposes of this analysis, we examine and compare alternatives in the subsequent sections over a 10-year period.

Table 4-1 summarizes the key hunting components associated with this alternative. Although these components have already been analyzed under Alternatives 2 through 6, to aid comparison we analyze them here in aggregate with the strike limits and other provisions described in Subsection 2.1, Alternative 7.

4.1.7.1 Potential Timing of a Hunt and Number of Hunting Days

As described above, hunt seasons would alternate between winter/spring hunts and summer/fall hunts. The hunting season during the winter/spring hunt mirrors the December 1 – May 31 period proposed by the Tribe in Alternative 2. Because Alternative 7 would have the same conditions as Alternative 2 regarding the hunt area, season, and methods, we assume there would be the same number of hunting days and scouting days under Alternative 7 as under Alternative 2. Thus, we anticipate up to 60 days of hunting and hunting-related activities in winter/spring hunts under Alternative 7. To summarize, we expect days of combined scouting, training, and hunting under Alternative 3 to occur as follows:

- Most likely: March through May
    - 43.3 scouting days, 33.2 hunting days
- Less likely: December through February
    - 17.1 scouting days, 9.3 hunting days

Summer/fall hunts are less restricted by ocean and weather conditions, as described in Subsection 4.1.4.1. Instead, the estimated number of hunting days that may take place in the summer/fall hunting season is restricted only by the hunters' ability to locate and strike a whale. According to an analysis by the Tribe (J. Scordino, Pers. Comm., Makah Tribe Marine Mammal Biologist, July 31, 2013), a reasonable estimate for the maximum number of days it would take to locate and strike a *male PCFG* whale is 7 days. Under Alternative 7, the hunt is not restricted to known males during the summer/fall.

Assuming a 50:50 sex ratio (see Subsection 3.4.3.4.1, Sex Ratio of PCFG Whales), the number of whales available to hunters under this alternative is effectively double that used to estimate the amount of time it would take to locate and strike a known male. However, the analysis by the Tribe provides the best available data, so our analysis under Alternative 7 maintains the assumption that it will take a maximum of 7 days for hunters to locate and strike a whale. This allows for a precautionary approach in this case, as the Tribe may strike a male or female PCFG whale unless or until the limit of 16 PCFG whales or 8 PCFG females is reached. Also, Alternative 7 allows up to two strikes in summer/fall hunts but only if the first strike results in a struck and lost whale. Therefore, it is possible that summer/fall hunts would involve up to 14 days of hunting if the first strike does not result in a landed whale, or up to 7 days if the first struck whale is landed.

For the limited 10-year waiver period under this alternative, there could be a maximum of five winter/spring hunting seasons and five summer/fall hunting seasons. This amounts to up to 300 days of hunting and hunting-related activities in winter/spring hunts during the waiver period (60 hunting days per year times 5 years) and up to 70 days of hunting-related activities in summer/fall hunts (14 hunting days per year times 5 years). Thus, under Alternative 7, there could be an average of 37 hunting days per year over the waiver period (370 total hunting days divided by 10 years).

However, it is possible that the Tribe may not receive authorization to hunt during some or all of the winter/spring hunt seasons. This could happen, for example, if the Tribe did not obtain an ITA for WNP gray whales. Under this scenario, it is possible that the Tribe would not be authorized to hunt at all during the winter/spring seasons, meaning that only 5 total seasons of hunting (during the summer/fall months) would occur over the waiver period This amounts to up to 70 days of hunting-related activities in summer/fall hunts (14 hunting days per year times 5 years) and an average of 7 hunting days per year throughout the waiver period (70 total hunting days divided by 10 years). Also, if the tribe conducted a winter/spring hunt and accidentally struck a WNP gray whale (a statistically improbable event), then all hunting would be suspended unless and until NMFS determined that measures had been taken to ensure no additional WNP gray whales are struck during the duration of the permit. This would result in a cease hunt for the duration of the permit, unless measures were identified to ensure no additional WNPs would be taken. Hunting could remain suspended for some, if not all, of the remaining winter/spring hunt seasons for the duration of the waiver period. Therefore, there could be some intermediate number of winter/spring hunt seasons over the course of the waiver period between the minimum of 0 if the Tribe does not receive an ITA and maximum of 5 if they do receive an ITA and do not strike a WNP gray whale.

4.1.7.2 Potential Number and Types of Vessels

The hunt under Alternative 7 would involve the same number and types of vessels as the hunt under Alternative 2.

4.1.7.3 Potential Number of ENP and PCFG Whales Killed; Likelihood of Striking a WNP Whale; Likely Number of Whales Harvested

Potential Number of ENP Whales Killed and Harvested

The maximum potential number of ENP whales killed under Alternative 7 would be 25 over a 10-year waiver period (averaging 2.5 whales killed per year) (Table 4-13). Up to three whales may be killed in winter/spring hunts, and up to two whales may be killed in summer/fall hunts, if the first whale was struck and lost. Only one whale may be harvested in summer/fall hunts, so it is possible that in some years only one will be killed. However, we assume that all struck and lost whales subsequently die. This level of mortality represents 0.017 percent of the ENP gray whale population and 0.61 percent or 1.2 percent of PBR (based on the informational estimates of PBR calculated in Subsection 3.4.3.3.4 ENP Status, Carrying Capacity, and Related Estimates). This level of mortality would not be likely to have a discernable effect on the ENP stock's abundance or rate of growth or on the stock's abundance relative to OSP due to the small percentage of the stock that could be affected.

If the Tribe receives authorization to hunt during the winter/spring season every year, Alternative 7 would result in higher mortality than the No-action Alternative and Alternatives 4 and 5 but lower mortality than Alternatives 2, 3, and 6. Removing the winter/spring hunts from the annual mortality estimation would reduce the overall mortality of the hunt under Alternative 7 to the same level as Alternative 4. Other scenarios, where the Tribe hunted in some but not all winter/spring seasons, could result in levels of annual mortality that fall somewhere in between the values examined above, none of which would be likely to lead to discernible effects on the ENP gray whale stock's abundance.

The total number of ENP whales killed under Alternative 7 could also be limited by the number of PCFG whales struck, as well as by low abundance thresholds for the PCFG and for the ENP stock in any given year. In addition to a WNP gray whale strike, hunting would cease under the following potential scenarios: (1) the total PCFG strike limit of 16 whales is reached; (2) the total PCFG female strike limit of eight whales is reached; (3) the most recent or forecasted PCFG abundance estimate falls below 192 whales; (4) the most recent or forecasted PCFG minimum abundance estimate falls below 171 whales; or (5) NMFS sets a low abundance threshold for the ENP stock and the stock's abundance estimate falls below that threshold of either (a) 11,000, (b) 16,000, or (c) 18,000 whales. If either of the first two conditions were met, the hunt would cease for the remainder of the 10-year waiver period.

If any of the abundance estimates for PCFG or ENP gray whales dropped below their thresholds, the hunt would cease until the relevant estimate(s) increased to above the threshold.

Maximum and Likely Number of PCFG, OR-SVI, and Makah U&A Whales Killed

Under Alternative 7, the maximum number of PCFG whales that may be killed is 16 over the 10-year waiver period, with an additional limit of eight strikes on PCFG females. In summer/fall hunts, we assume that 100% of the whales struck would be members of the PCFG. Because the hunt would occur in the Makah U&A, any PCFG whale killed during the summer/fall would also be an OR-SVI and Makah U&A whale. Therefore, during summer/fall hunts when the strike limit is two whales, up to two PCFG whales—and, therefore, two OR-SVI and two Makah U&A whales—could be killed, unless the first strike results in a landed whale, which would end the hunt for that season.

Although a total of 16 PCFG whales might be killed over the 10-year waiver period, it is unlikely that 16 would actually be killed, given the proportion of PCFG whales present in the Makah U&A during the winter and spring months. During winter/spring hunts, the mixing proportions for PCFG, OR-SVI, and Makah U&A whales during the time when the hunt would take place are 27.3%, 26.2%, and 23.4%, respectively, as described in subsection 4.1.2.3 above. If all three strikes were used in a winter/spring hunt, it is likely that 0.82 of those would be on PCFG whales (3 strikes times 27.3%), 0.79 on OR-SVI whales (3 strikes times 26.2%), and 0.70 on Makah U&A whales (3 strikes times 23.4%). To aid comparison with other alternatives, Table 4-13 summarizes these Alternative 7 strike estimates annually and over the span of 6 and 10 years. Assuming that the Tribe receives authorization to hunt every year in alternating seasons, the average PCFG mortality would be 1.4 whales per year. This would be higher than expected under the No-action Alternative and under Alternatives 4, 5, and 6, but less than under Alternatives 2 and 3. It is also lower than the informational PBR of 3.5 whales calculated by NMFS (Carretta et al. 2023).

Likelihood of Striking a WNP Whale

Moore et al. (2023) provides a detailed analysis for the probability of striking a WNP whale under Alternative 7. Based on the best available information, that analysis assumed that WNP whales would only be encountered during winter/spring hunts because such whales have not been sighted in or near the Makah U&A during the summer/fall months. Using the best data currently available on the presence of WNP whales in the ENP range and assuming that all allowable strikes and training harpoon throws are utilized throughout the course of the 10-year waiver period during winter/spring months, they estimate that for an individual strike on a gray whale, the expected probability of it being a WNP whale is between 0.8% and 1.2%, assuming an ENP abundance of between 16,000 and 11,000 animals

respectively. According to Moore et al. (2023), the probability of striking one WNP gray whale over the 10-year waiver period is between 11.1 and 16.3%, assuming all 15 winter/spring strikes are utilized. In other words, we would expect one WNP whale to be struck every 61 to 90 years. It is unlikely that all of the assumptions of this analysis will be met, as it is unlikely that all hunt activities will occur in the winter/spring months and that the full allowance of strikes and training harpoon throws will be utilized each year. Therefore, these are precautionary estimates representing the maximum potential impact to WNP gray whales under Alternative 7. To aid comparison with other alternatives, Table 4-13 summarizes these Alternative 7 strike estimates annually and over the span of 6 and 10 years. The risk to WNP whales under Alternative 7 is less than under Alternatives 2, 3, 5, and 6 but more than under the No-action Alternative and Alternative 4, assuming the Tribe receives authorization to hunt in the winter/spring months. Under this alternative, if a struck whale was identified as a member of the WNP stock, hunting would cease until measures have been taken to prevent striking another WNP whale.

4.1.7.4 Potential Number of Unsuccessful Harpoon Attempts and Approaches

During winter/spring hunts under Alternative 7, we expect the ratio of unsuccessful harpoon attempts to successful strikes would be similar to Alternative 2, resulting in 18 unsuccessful harpoon attempts (three strikes times six unsuccessful harpoon attempts) on ENP gray whales. However, consistent with our assumptions for Alternative 4, the ratio could be lower during Alternative 7's summer/fall hunts because whales approached during the feeding season may be more likely to be milling and less likely to be traveling than whales found during the migratory season, making them more vulnerable to a successful strike. Nevertheless, for this analysis and consistent with our assumptions for Alternative 4, we use the observed ratio of 6:1 for Alternative 7, as that represents the best information available based on experience from the 1999 and 2000 hunts. With up to two strikes under Alternative 7, we would expect 12 unsuccessful harpoon attempts during summer/fall hunts. Unsuccessful harpoon attempts on a whale that has already been struck do not count against the limit of attempts that may be authorized under a permit. Assuming that the Tribe receives authorization to hunt in the winter/spring months, this would result in an average of 15 unsuccessful strike attempts per year over the 10-year waiver period. This would result in more behavioral disturbance from strike attempts under Alternative 7 than under the No-action Alternative and Alternative 4, but less than under Alternatives 2, 3, 5, and 6.

Consistent with Alternatives 2, 3, and 6, we assume there could be a maximum of 353 approaches on ENP gray whales per year. This would result in more behavioral disturbance due to approaches than under the No-action Alternative and Alternatives 4 and 5, unless the Tribe does not receive authorization to conduct hunting and training activities in the winter/spring seasons. These would be in the form of hunt-related approaches or approaches made by crews/vessels training to hunt. Some of

these approaches may be repeated incidents involving the same whale. We also estimated the number of PCFG, OR-SVI, and Makah U&A whales that may be subjected to unsuccessful harpoon attempts and approaches. However, if the Tribe is only authorized to hunt in the summer months, we assume that all whales approached would be PCFG whales. Therefore, the Tribe would be limited to 142 approaches per year. Our results are shown in Table 4-13.

Estimates for unsuccessful harpoon attempts and approaches on WNP whales are based on the analysis by Moore et al. (2023). Their analysis assumed that all approaches (hunting and training) in a given year would occur during the winter/spring when WNP whales may be present. Given that assumption, if 353 approaches are made every year during the 10-year waiver, we would expect up to 27.7 to 41.6 WNP whales to be approached (0.8% and 1.2% times 3,530 approaches) (Table 4-13). Thus, Alternative 7 would result in the same potential level of behavioral disturbance to WNP gray whales due to approaches as Alternatives 2, 3, and 6, but more than the No-action Alternative and Alternatives 4 and 5. However, it is likely that fewer than the maximum expected number of WNP whales would be approached because we would expect a substantial number of approaches to occur during the summer when ocean conditions are more favorable for training and, during summer/fall hunts, when approaches are restricted to July through October. If the Tribe does not receive permits for winter/spring hunts, unsuccessful strike attempts and approaches will be limited to the summer/fall hunt months when WNP gray whales are not expected to be present.

4.1.7.5 Potential Number of Shots Fired or Grenade Explosions

For the reasons described under Alternative 2 (Subsection 4.1.2.5), we estimate there would be 16 rifle shots and three grenade explosions (if grenades are used) for each harvested whale. In winter/spring hunts, we estimate up to 48 shots fired (16 shots times three whales harvested) and up to nine grenade explosions (three grenade explosions times three whales harvested) per year. In summer/fall hunts, only one whale may be harvested; however, two whales may be pursued and struck if the first whale is struck and lost. To be precautionary, in summer/fall hunts, we estimate up to 32 shots fired (16 shots times two whales) and up to six grenade explosions (three grenade explosions times two whales) per year. However, it is unlikely that all of these shots and explosions would occur if (1) the first whale is harvested or (2) it was struck and lost and able to evade hunters quickly and not elicit all of the estimated shots and explosions. If the Tribe receives authorization to hunt in the winter/spring months, the maximum average annual number of rifle shots and grenade explosions under Alternative 7 would be 40 and 8, respectively.

It is possible that rifle shots and grenade explosions could result in behavioral disturbance of nearby whales. Grenade explosions may also cause temporary hearing threshold shifts in gray whales.

However, it is unlikely that hunters would fire rifles or grenades at a whale before it has been "made fast" with a harpoon attached to a buoy. As a result, they can largely limit the impacts of gunshots and grenade explosions to the whale being harvested by first separating it from any nearby whales. In addition, effects would be related to the timing and location of the noise relative to the nearby whale's location and activity. Any noise from a gunshot would probably decay to ambient levels within 1 or 2 miles of the source, and the duration of the sound is expected to only last a few seconds. Given this, any disturbance from the use of weapons be temporary, and it is unlikely that these activities will have a discernable impact on the ENP gray whale stock's abundance, rate of growth, or distribution, or that these activities will affect their migration under this Alternative. Still, the risk of disturbance associated with rifle shots and grenade explosions under Alternative 7 is higher than under the No-action Alternative and Alternatives 4 and 5 but less than under Alternatives 2, 3, and 6.

Table 4-13. Estimated number of strikes, unsuccessful harpoon attempts, and approaches of ENP, PCFG, OR-SVI, Makah U&A, and WNP whales under Alternative 7.

Whales & Mixing Proportions	Number of Strikes				Number of Unsuccessful Harpoon Attempts				Number of Approaches		
	Winter/Spring Hunt / Summer/Fall Hunt				Winter/Spring Hunt / Summer/Fall Hunt						
	Annual	**6-Yr**	**10-Yr**	**10-Yr Total[a]**	**Annual**	**6-Yr**	**10-Yr**	**10-Yr Total[a]**	**Annual**	**6-Yr Total**	**10-Yr Total[a]**
ENP Winter/Spring = 100% Summer/Fall= 100%	3 / 2	9 / 6	15 / 10	25	18 / 12	54 / 36	90 / 60	150	353[b]/142[c]	2118[b]/852[c]	3530[b]/1420[c]
PCFG Winter/Spring = 27.3% Summer/Fall= 100%	0.82 / 2	2.5 / 6	4.1 / 10	14.1[d]	4.9 / 12	14.7 / 36	24.6 / 60	84.6	142[e]	852[e]	1420[e]
OR-SVI Winter/Spring = 26.2 % Summer/Fall= 100%	0.79 / 2	2.4 / 6	3.9 / 10	13.9	4.7 / 12	14.1 / 36	23.6 / 60	83.6	142[e]	852[e]	1420[e]
MUA Winter/Spring= 22.54% Summer/Fall= 100%	0.70 / 2	2.1 / 6	3.5 / 10	13.5	4.2 / 12	12.6 / 36	21.1 / 60	81.1	142[e]	852[e]	1420[e]
WNP Winter/Spring= 0.8-1.2% Summer/Fall= 0%	0.024-0.035 / 0	0.071-0.11 / 0	0.12-0.16 / 0	0.12-0.18	0.14-0.21 / 0	0.42-0.64 / 0	0.71-1.06 / 0	0.71-1.06	2.8-4.2[f]	16.6-25.0[f]	27.7-41.6[f]

a. The 10-Yr Total values for strike limits and unsuccessful harpoon attempts are based on the assumption that the Tribe will receive authorization for winter/spring hunts to occur in alternating years. Under this scenario, there will be 5 winter/spring hunts and 5 summer/fall hunts over the course of the waiver period. If the Tribe does not receive permits for winter/spring hunts, the 10-year totals are those values reported for Summer/Fall hunts under the preceding 10-yr columns.

b. The maximum approach estimates for ENP gray whales assume that the Tribe has received permits to conduct training and hunting approaches during the winter/spring months. The approach limits are the same for winter/spring hunt years and summer/fall hunt years, and they assume that each year the Tribe will make the maximum allowable approaches (hunting and training) on gray whales.

c. If the Tribe does not receive permits to conduct hunting and training activities in the winter/spring months, hunting and training approaches will be limited to the summer/fall months when we assume that every whale approached is a PCFG whale. Therefore, the number of approaches will be limited to 142 annually.

d. For comparison, the maximum allowable number of strikes on PCFG whales is 16 over the 10-year waiver period.

e. These PCFG, OR-SVI, and MUA approach estimates are conservative because they assume that all approaches (hunting and training) in a given year occur during the summer/fall period when 100% of the whales encountered are assumed to be PCFG, OR-SVI, and MUA whales, and that the Tribe will use all of the allowable approaches for PCFG whales (142 approaches). If the Tribe receives a permit to conduct hunting and training activities to occur in the winter/spring months, we would expect some of the approaches to occur during the winter/spring period.

f. These WNP approach estimates–based on Moore et al. (2023)–are conservative because they assume that all approaches (hunting and training) in a given year occur during the winter/spring period when WNP whales may be present. Realistically, we would expect a substantial number of approaches to occur outside this period, i.e., during the summer when ocean conditions are more favorable for training and, in summer/fall hunts, when hunting approaches are restricted to July–October.

4.1.7.6 Low Abundance Thresholds

The impacts to the affected environment under Alternative 7 are analyzed without a low abundance threshold for the ENP stock (Preferred) as well as with three potential thresholds, below which hunting would cease. Regardless of whether a low-abundance threshold is defined, NMFS would retain discretion to deny issuance of a hunt permit if NMFS determined that a hunt would adversely affect the ENP gray whale stock's status. The alternative of not including an ENP gray whale low-abundance threshold provides NMFS the most flexibility to evaluate the effect of an individual hunt permit on the ENP gray whale stock based on contemporaneous environmental conditions and the best scientific information available at that time.

Sub-alternative 7(a) would set a low abundance threshold of 11,000 ENP gray whales. This threshold represents the lowest estimated abundance from which the population has increased in the 54-year time series of data for the stock. Under Sub-alternative 7(b), the abundance threshold would be 16,000 animals. This threshold is based on the OSP analysis conducted by Punt and Wade (2012), which concluded that the MNPL for the ENP gray whale stock at that time was approximately 16,000 whales. Setting the abundance threshold at the estimated MNPL for the stock would prevent a hunt from taking place if the population dropped below OSP as calculated in 2012, however, recent information suggests that the stock's OSP may have changed since Punt and Wade's 2012 analysis (see Subsection 3.4.3.3.4, ENP Status, Carrying Capacity, and Related Estimates). Finally, under Sub-alternative 7(c), the abundance threshold would be 18,000 animals. This threshold uses the upper 95% confidence interval of the most recent abundance estimate before the start of the ongoing 2019 UME (30,000 whales) as an estimate of carrying capacity (K) to update the Punt and Wade (2012) analysis, resulting in an estimated MNPL of approximately 18,000 whales. Based on the most recent ENP gray whale stock abundance estimate, hunting could be permitted under Sub-alternative 7(a) but not under Sub-alternatives 7(b) and (c) until current abundance increased. None of the low-abundance thresholds represent an adaptive management approach which accounts for current environmental conditions or consider the ENP gray whale stock's status relative to current carrying capacity.

Alternative 7 would implement two abundance thresholds for PCFG gray whales in tandem with one another: an abundance estimate (N) of 192 whales and a minimum abundance estimate (N_{min}) of 171 whales. The most recent or forecasted abundance *and* minimum abundance estimates must remain above these levels for hunting to be authorized. These thresholds represent the lowest population abundance estimates during a recent stable period (1996 through 2017) during which the population has grown in the time series of data from 1996 through 2017.

Although it is difficult to determine the likelihood of triggering any of the abundance thresholds during the 10-year waiver period, implementing such a threshold increases the probability that hunting may cease for one or more years. This would result in fewer whales struck, subjected to unsuccessful harpoon attempts, and approached than the estimates reported in Table 4-13.

4.2 Water Quality

4.2.1 Introduction

This subsection addresses the potential for the alternatives to affect water quality in the action area, including marine water and groundwater. No hunt-related activities, with the possible exception of whale butchering activities, would take place above the high-tide line. There is no potential to affect surface water quality, including streams and tributaries in Water Resource Inventory Areas 19 and 20. Two issues pertain to the potential effects under each alternative on water quality of whale hunt-related activities. First is the potential for spills of vessel fuel or other contaminants as a result of collisions or other incidents involving marine vessels associated with the hunt, including observers and protesters. Second is the potential for groundwater contamination because of leaks of fluids from whale carcasses or tissues that may be disposed of eventually in a landfill. The method for disposing of any unused portions of harvested whales could include towing out to sea or disposal in a landfill (currently located several hundred miles inland in Klickitat County, Washington) (refer to Subsection 3.2.7, Solid Waste Disposal). This analysis addresses the effects of temporary storage at the Makah transfer station. Effects of disposal at sea are addressed in Subsection 4.3, Marine Habitat and Species.

None of the alternatives has the potential to affect drinking water quality, because no hunt-related activities would have the potential to affect current or future drinking water sources in the action area. The potential effects of whale butchering activities on water quality for the marine aquatic ecosystem would be negligible because the amount and longevity of any toxins would be minimal. Similarly, there would be no potential for any long-term effects on the management of shellfish beds in the action area. The following subsections discuss these points in greater detail.

4.2.1.1 Drinking Water Sources

As described in Subsection 3.2.4, Drinking Water Sources, all drinking water in the action area comes from surface water sources. Under the action alternatives, activities related to hunting and butchering whales would occur in marine or intertidal areas and therefore would not expose any current drinking water sources to whale-derived contaminants. Of the three potential future water sources identified in Subsection 3.2.4, Drinking Water Sources, two are surface water and would likewise be unaffected. The third option is a desalinization plant at the outlet of the Wa'atch River. The mechanism used to

treat the water at such a plant (reverse osmosis) would produce water that meets federal standards for drinking water even if contaminants are present at the water collection site (for example, reverse osmosis is used to polish secondary effluent from wastewater treatment plants, rendering it suitable for use as drinking water). Therefore, there is no potential for whale-derived contaminants to affect any of the potential future drinking water sources that have been identified in the action area. Temporary storage of whale carcass material at a transfer station would have the potential to affect only groundwater, so no drinking water sources could be affected. The potential effects on groundwater are discussed in Subsection 4.2.2.2, Groundwater Contamination.

4.2.1.2 Marine Waters

In marine and intertidal waters, whale hunting and butchering under the action alternatives would produce two broad classes of potential contaminants: organic material (e.g., blood, lymph, and digestive tract contents) and bioaccumulated contaminants (e.g., PCBs, DDT). During a successful whale hunt, the initial strike and kill would be expected to release substantial amounts of organic matter, which would continue to leak out of the carcass as it is hauled to the beach. The likely effects of this material would be attraction of predators to the blood scent, avoidance of blood by common prey fish species, and secondary effects of decreased dissolved oxygen associated with the breakdown of the organic material by marine bacteria. These effects would extend over a relatively short period (likely several hours) and would have a very low probability of affecting the marine environment in any detectable manner for more than a day or two. Struck and lost whales may also release organic material and bioaccumulated contaminants into the marine environment in a similar manner to whales that die and decompose at sea, however they would not be hauled to the beach and therefore these impacts would remain offshore and would not likely be detectable above the baseline levels of the No Action Alternative.

Any bioaccumulated contaminants in a whale carcass would be associated primarily with whale blubber, most of which would be removed and used for subsistence or ceremonial purposes. As described in Subsection 1.4.2 (Summary of Recent Makah Whaling — 1998 through 2007), following the successful hunt in 1999, Makah tribal members removed almost all edible portions of the meat and blubber from the whale within approximately 12 hours of towing the whale to shore. Under the action alternatives, if hunting and butchering were to proceed as they did in 1999, there would be little opportunity for contaminant release into the environment through decomposition while a whale is on the beach because the portions with the highest concentrations of contaminants (primarily blubber) would be removed in approximately 12 hours. If the unused portions of the carcass were towed out to sea for post-harvest disposal, some bioaccumulated contaminants might be released into the marine

ecosystem. The amount of toxins released from a flensed carcass, however, would be substantially less than the amount from a whale that died and decomposed entirely at sea. Given the size of the ocean area in which carcasses would be disposed, the removal of most of the blubber from carcasses prior to disposal, and the likely death and decomposition of some whales in the area naturally, the expected impact to the marine environment from carcass disposal would be negligible in any given year or over a period of years.

4.2.1.3 Shellfish Beds

As noted in Subsection 3.2.5 (Shellfish), shellfish beds in the action area can be closed to harvest because of the presence of human fecal coliforms or toxic algal blooms. Fecal coliforms are not harmful to shellfish but may be used to indicate the presence of sewage-borne organisms (pathogens) that cause disease in humans. The release of fecal coliforms into intertidal waters, therefore, would have the potential to affect aquaculture or subsistence harvest of shellfish only if the Washington Department of Health or Makah Fisheries chose to close a beach to harvest as a precautionary measure. Under the action alternatives, butchering a whale on the beach might release fecal coliforms into the intertidal area, where filter-feeding shellfish could accumulate them. Fecal coliforms from a whale, however, do not indicate an elevated risk of the presence of human pathogens. In addition, fecal coliforms are freshwater organisms that typically start to die off within 12 to 48 hours of exposure to marine water.

Regarding toxic algal blooms, research in Puget Sound has not established a statistically significant link between natural or human activities and toxic algal blooms. There is no evidence to suggest that the death of a whale (an ongoing natural process) would affect the probability of a toxic algal bloom occurring and thus requiring a shellfish harvest closure.

Based on the information above, it is improbable that whale hunt-related activities under the action alternatives would lead to long-term closures of shellfish beds inside the Makah U&A. If, through independent monitoring, the Washington Department of Health or Makah Fisheries found elevated levels of fecal coliforms and closed a beach (which would represent a cautious response to the presence of fecal coliforms in a whale carcass on the beach), the closure could last a few days until the waste material from the whale was diluted and dispersed by the tidal activity.

4.2.2 Evaluation Criteria

Two criteria were used to determine the potential for effects on water quality under the alternatives. The first is the likelihood of an increase in the risk associated with fuel spills or the introduction of

other toxic substances into the environment. The second is the likelihood of an increase in the risk associated with leakage from whale carcass material temporarily stored at the Makah Transfer Station.

4.2.2.1 Spills

Spills could result from collisions between vessels, equipment failure, or accidental release (e.g., while fueling or if a vessel capsized). No spills were reported from the 1999 and 2000 hunts, despite a collision between a protest vessel and a law enforcement vessel. If any spills occurred, effects would be minor and short-lived, even if they occurred in a semi-contained area such as Neah Bay. The volume of fuel or other contaminants carried by any hunt-related vessels would be miniscule compared to the volume of water in any potential receiving waters (e.g., Neah Bay, the Strait of Juan de Fuca, and the Pacific Ocean). A spill of fuel or similar fluids would not mix with water but would form a thin layer on the surface, continually spreading while it evaporated, broke apart, was hydrolyzed by ultraviolet light, and was decomposed by bacteria. This would probably occur over hours or days. The nearshore portion of the Makah U&A corresponds largely with the area to be avoided for the OCNMS, which was designated with the intention of reducing the potential for catastrophic oil spills from large ships (greater than 400 gross tons) carrying large amounts of bunker fuel. Any vessels involved in whale hunts, protest activities, or law enforcement would be substantially smaller than that, so any spills in the Makah U&A would not violate the intention of the area to be avoided.

The risk of spills would depend primarily on the amount of hunt-related vessel traffic in the action area, including Makah vessels and associated protest, media, and law enforcement vessels. Vessels and aircraft associated with each hunt would likely be similar to those associated with the previous hunts, as described in Subsection 3.11.3.2.1, Atmospheric Noise. It is possible that the amount of vessel traffic associated with each hunting expedition (including observation, protests, law enforcement, and media coverage) would vary under the action alternatives. For example, hunts conducted during summer (i.e., under Alternative 4) could attract more observers, protesters, or media coverage than hunts at other times of year. Alternatives that allow more hunts might attract less public interest over time and, therefore, less media coverage. Because of the difficulty of predicting such variations and how they might affect the precise amount of vessel traffic, this analysis assumes that each hunting expedition would be accompanied by the same amount of vessel traffic.

The risk of spills might also depend on the hunting season. Hunts conducted during the winter months might face a higher risk of encountering unanticipated storms that could cause vessels to capsize, as compared with hunts conducted during the summer. Thus, the risk of spills is likely to depend on the number of days with hunt-related trips and the season when hunting occurs. Under any of the action

alternatives, the risk from oil spills could be addressed by modifying or supplementing existing spill response plans (i.e. NWACP 2020) (Subsection 3.2.6, Spill Prevention).

4.2.2.2 Groundwater Contamination

As noted above, the method of disposing of any unused portions of harvested whales would either be disposal at sea or in a distant landfill after temporary storage at the Makah Transfer Station. The method would likely depend on the location where the whale was landed and butchered. Under the action alternatives, if any unused portions of whale carcasses were placed in the Makah Transfer Station, the potential would exist for contaminants from the carcass to leak and mix with groundwater. The risk of groundwater contamination would depend on 1) the concentration of water-soluble contaminants in the unused portions of the carcass, and 2) the amount of tissue delivered to the facility. The greatest concentrations of contaminants occur in blubber, most of which would be removed and used for subsistence or ceremonial purposes. Contaminants in any residual blubber on a carcass would likely be hydrophobic substances such as PCBs and DDT. If any such substances leaked at the Makah Transfer Station, they would adhere to soils and would have a very low probability of reaching groundwater in quantities likely to be toxic. Groundwater, however, does not serve as a drinking water source in the action area.

It is not possible to predict in advance the proportion of harvested whale carcasses that would be disposed of via the Makah Transfer Station, the amount of material on any of those carcasses, or the concentration of contaminants in any of those carcasses. Therefore, the most reliable indicator of the potential risk of groundwater contamination is the number of whales that would be harvested under a particular alternative. This number would depend primarily on harvest limits. In addition, restrictions on hunting seasons and on the harvest of identified whales might affect the Tribe's ability to harvest the full limit allowed.

4.2.3 Evaluation of Alternatives

The following subsections consider the potential for the alternatives to pose risks to water quality in the action area. For each alternative, the discussion addresses the potential number of occasions on which hunt-related activity may pose a risk of spills, and the potential amount of waste material from harvested whales that may pose a risk of groundwater contamination.

The lowest risk of adverse effects on water quality would occur under the No-action Alternative because no whale hunts would be permitted. The risk under the action alternatives would increase compared to the No-action Alternative, with the amount of increase dependent on the number of days of scouting, training, and hunting, the hunting season, and the number of whales harvested. Table 4-1

identifies the number of likely days of hunting and the number of whales likely to be harvested under each alternative, and Subsection 4.1, Introduction, describes the rationale for those numbers.

Compared to the No-action Alternative, the risk of spills would increase under any of the action alternatives because of increases in vessel traffic on days when tribal members are scouting or hunting for whales. The greatest increases in the risk of spills would occur under Alternatives 2, 3, and 6, under which hunt-related trips would likely occur on approximately 60 days from December through May when vessels might encounter unanticipated storms and capsize. The increased risk of spills would be lower under Alternative 5 than under Alternatives 2, 3, and 6 because hunt-related trips would likely occur on approximately 22 days in December and May. The increased risk would be even lower under Alternative 4, under which hunt-related trips would likely occur on only 7 days. In addition, hunt-related trips under Alternative 4 could be conducted during the summer months, when the risk of vessels capsizing in unanticipated storms would be reduced compared to the other action alternatives. Alternative 7 is associated with an overall average of 37 days per year with hunt-related activities over the course of the 10-year waiver period; however, those days are split between winter and summer months. Up to 60 days with hunt-related trips could occur in winter/spring hunt years, while up to 14 could occur in summer/fall hunt years if the first whale struck by hunters is struck and lost.

As described above, the most reliable indicator of the potential risk of groundwater contamination is the number of whales that would be harvested under a particular alternative. The No-action Alternative carries the least risk of groundwater contamination because no whales would be delivered to a distant landfill via the Makah Transfer Station beyond those that might be delivered under current conditions (e.g., the possible disposal of a stranded animal). Under Alternative 4, the number of whale carcasses could increase, relative to the No-action Alternative, by a maximum of one every other year (under current conditions). The maximum potential increase in the number of whale carcasses delivered to the Makah Transfer Station would be greater under the other action alternatives, ranging from an average of 2 per year under Alternative 7 to as many as 5 per year under Alternatives 2, 3, and 5. However, as discussed in the individual analyses below, the actual number would likely be less because of restrictions on mortality of PCFG whales.

Under Alternatives 6 and 7, the waiver of the MMPA take moratorium and implementing regulations would lapse after 10 years, and it is not possible to predict whether they would be replaced with a new waiver and implementing regulations or what the terms of any new waiver and regulations would be. Therefore, the analyses for Alternatives 6 and 7 consider effects only over a 10-year period.

4.2.3.1 Alternative 1, No Action

Under the No-action Alternative, no Makah whale hunt would be authorized and no whale hunting or associated activities (such as vessel traffic, protests, whale butchering, and carcass disposal) would be expected to occur in the action area. Therefore, the amount of marine vessel traffic and the risk of spills in the action area would not differ from current levels. With the possible exception of waste material from drift whales (which could be towed out to sea or disposed of on land), no whale tissue or carcasses would be delivered to the Makah Transfer Station. If any leakage occurred at the station, the effluent would not be different from current conditions and the risk of groundwater contamination would remain at current levels under the No-action Alternative.

4.2.3.2 Alternative 2, Tribe's Proposed Action

Under Alternative 2, vessel traffic associated with hunt-related trips would be expected to occur on approximately 60 days from December through May, primarily during the spring. Compared to the No-action Alternative (under which there would be no hunt-related vessel traffic), this would result in an increased risk of fuels or other contaminants being released into the marine environment. As described above, because the vessels associated with hunting would be small, any spills would be localized and rapidly diluted to undetectable concentrations in the Pacific Ocean or local bays. Non-water-soluble contaminants such as petroleum-based fuels would disperse and break down in hours or days. Also, risks from spills could be addressed by modifying or supplementing existing spill response plans.

Under Alternative 2, effects to groundwater are expected to be negligible. The limit on the number of harvested whales would be an average of four whales per year over 6 years, with no more than five in any one year. The limit on the number of PCFG whales killed per year would be three, based on current population estimates (Table 4-1). In addition, only PCFG whales harvested, not whales struck and lost, would be counted toward that limit. It is therefore unlikely that limits on PCFG whale mortality would restrict the total number of whales harvested per year under Alternative 2. It is not possible to predict the proportion of carcasses from those harvested whales that may be disposed of in a distant landfill or the Makah Transfer Station, but the maximum number would correspond to the harvest limits (an average of four per year and no more than five in any single year). If any leakage occurred, the effluent might contain contaminants, which could enter groundwater. However, groundwater is not used as a source of drinking water in the action area. Thus, for the reasons described above, there would be no expected effect on drinking water sources.

4.2.3.3 Alternative 3, Offshore Hunt

Alternative 3 would include the same limits on the number of whales harvested as Alternative 2, but would prohibit Makah hunters from making an initial strike on a gray whale within 5 miles (8 km) of shore

and would impose additional restrictions on the mortality of PCFG whales. As under Alternative 2, vessel traffic associated with hunt-related trips under Alternative 3 would likely occur on approximately 60 days from December through May. Compared to the No-action Alternative (under which there would be no hunt-related vessel traffic), this would result in an increased risk of fuels or other contaminants being released into the marine environment.

Compared to Alternative 2, the risk of fuels or other contaminants being released into the marine environment may be greater because the hunting party would likely be in a motorized vessel rather than a canoe, resulting in a greater number of motorized vessels engaged in each hunt-related trip. As described above, because the vessels associated with hunting would be small, any spills would be rapidly diluted to undetectable concentrations in the Pacific Ocean or local bays. Non-water-soluble contaminants such as petroleum-based fuels would disperse and break down in hours or days. Also, risks from spills could be addressed by modifying or supplementing existing spill response plans.

Under Alternative 3, effects to groundwater are expected to be negligible. The maximum number of whales that could be harvested under Alternative 3 would be the same as under Alternative 2 (an average of four per year, with no more than five in any one year). In contrast to Alternative 2, however, whales struck and lost would be counted toward the annual mortality limit for PCFG whales, potentially reducing the total number of whales that could be harvested in some years. Under some scenarios, it is possible that hunting activities for a given year could be curtailed before any whales are successfully harvested (Subsection 4.1.3, Alternative 3, Offshore Hunt). Under current conditions, up to four whales may be harvested per year under Alternative 3 (Table 4-5). Alternative 3 could thus have a smaller increase (relative to the No-action Alternative) in the risk of groundwater contamination than would Alternative 2. However, groundwater is not used as a source of drinking water in the action area. Thus, for the reasons described above, there would be no expected effect on drinking water sources.

4.2.3.4 Alternative 4, Summer/Fall Hunt

Under Alternative 4, the hunting season would extend from June 1 through November 30 instead of December through May. The maximum number of whales harvested under current conditions would be limited to one ENP male whale every other year. Based on the expectation that locating and striking a known ENP male would take no more than 7 days (Subsection 4.1.4, Alternative 4, Summer/Fall Hunt), vessel traffic associated with hunt-related trips under Alternative 4 would be likely to occur on a total of 7 days every other year. Compared to the No-action Alternative (under which there would be no hunt-related vessel traffic), Alternative 4 would result in an increased risk of fuels or other contaminants being released into the marine environment. The increase would, however, be smaller than under any of the other action alternatives because vessel traffic would be likely to occur on 7 days

every other year, compared to approximately 60 days per year under Alternatives 2 and 3. In addition, hunt-related trips under Alternative 4 could be conducted during the summer months when the risk of vessels capsizing in unanticipated storms would be reduced compared to the other action alternatives. Also, risks from spills could be addressed by modifying or supplementing existing spill response plans.

Under Alternative 4, effects to groundwater are expected to be negligible. The maximum number of whales that could be harvested under Alternative 4 (under current conditions) would be limited to one every other year. It is possible, however, that no whales could be harvested in some additional years if tribal hunters are unable to locate and strike a known ENP male or if a whale is struck and lost (in which case the hunt would be ended for the year). Alternative 4 would therefore result in an increased risk of groundwater contamination from material delivered to the Makah Transfer Station, relative to the No-action Alternative, but the increase would be smaller than under any of the other action alternatives. However, groundwater is not used as a source of drinking water in the action area. Thus, for the reasons described above, there would be no expected effect on drinking water sources.

4.2.3.5 Alternative 5, Split-season Hunt

Under Alternative 5, the hunting season would be 3 weeks in December and 3 weeks in May, in contrast to the 6-month-long hunting seasons under the other action alternatives. In addition, the landing of a single PCFG whale, or the striking and losing of a single whale, would end the hunt for any given year.

Based on the length of the hunting season, vessel traffic associated with hunt-related trips under Alternative 5 would likely occur on a total of 22 days per year. This could decrease to 0 days in years in which the hunt is on hiatus to allow the PCFG mortality limit to re-set at one whale. Compared to the No-action Alternative (under which there would be no hunt-related vessel traffic), Alternative 5 would result in an increased risk of fuels or other contaminants being released into the marine environment. The increase would be greater than under Alternative 4 (which would be expected to result in 7 days of hunt-related vessel traffic per year) but less than under Alternatives 2, 3, 6, and 7 (which would be expected to result in approximately 37, on average, to 60 days of hunt-related vessel traffic per year). As under the other action alternatives, risks from spills could be addressed by modifying or supplementing existing spill response plans.

Under Alternative 5, effects to groundwater are expected to be negligible. Based on the constraints imposed by the hunting season and the PCFG mortality limit, it is expected that the Tribe would harvest up to one whale per year (Subsection 4.1.5, Alternative 5, Split-season Hunt). During years in which no whales are struck and lost, and no PCFG whales are killed, the maximum limit for the number of whales harvested would be the same as under Alternatives 2 and 3. Compared to the No-action Alternative, therefore, Alternative 5 would result in an increased potential for contaminants to enter groundwater. Under some

scenarios, the potential increase could be as high as under Alternative 2, but the more likely increase would be similar to that expected for Alternative 4. However, groundwater is not used as a source of drinking water in the action area. Thus, for the reasons described above, there would be no expected effect on drinking water sources.

4.2.3.6 Alternative 6, Different Limits on Strikes and PCFG, and Limited Duration of Regulations and Permits

Alternative 6 would have the same conditions as Alternative 2 regarding the hunt area, season, and methods and would, therefore, result in the same number of days (60) with hunt-related trips. Thus, the increased risk of fuels or other contaminants being released into the marine environment would be about the same as under Alternatives 2 and 3, compared to the No-action Alternative. As under the other action alternative, risks from spills could be addressed by modifying or supplementing existing spill response plans.

Under Alternative 6, effects to groundwater are expected to be negligible. Alternative 6 would include greater restrictions than Alternatives 2 and 3 on the maximum number of whales that could be killed per year and per 2 years, resulting in a maximum of 3.5 whales harvested per year on average. As a result, Alternative 6 would result in an increased potential, compared to the No-action Alternative, for contaminants to enter groundwater. This increase would be less than under Alternatives 2 and 3 (under which a maximum of four whales could be harvested per year on average) but greater than under Alternatives 4, 5, and 7 (under which a maximum of one to 2, on average, whales could be harvested per year). However, groundwater is not used as a source of drinking water in the action area. Thus, for the reasons described above, there would be no expected effect on drinking water sources.

4.2.3.7 Alternative 7, Composite Alternative—Preferred

As with the other action alternatives, Alternative 7 could result in an increased risk of fuel or other contaminants being spilled into the marine environment compared to the No-action Alternative. During winter/spring hunts, an estimated 60 days of hunt-related activities would occur during a period with rough ocean conditions, increasing the risk of spills due to capsizing or colliding. During summer/fall hunts, there would be 7-14 days with hunt-related trips during a period when more favorable ocean conditions would lessen the risk of such spills. However, because of the more favorable conditions, more recreational vessels could be present in the action area, resulting in an increased risk of vessel collisions. This impact may be mitigated by the small number of days involving hunt-related trips, the location of the hunts in this large and remote area of the Pacific Ocean, the small size of vessels, and U.S. Coast Guard regulations associated with the moving exclusionary zone.

To compare the overall impact of Alternative 7 to the impacts of the other six alternatives, we use an annual average number of 37 days with hunt-related trips (300 winter/spring days plus 70 summer/fall days divided by the 10-year span of the waiver period) (Subsection 4.1.7 Alternative 7, Composite Alternative). Alternative 7 would, therefore, result in a smaller risk of spills than Alternatives 2, 3, and 6 (each with 60 days of hunt-related trips). However, Alternative 7 would result in a greater risk than the No-action Alternative (0 days), as well as Alternatives 4 and 5 (14 and 22 days of hunt-related trips, respectively). As under the other action alternative, risks from spills could be addressed by modifying or supplementing existing spill response plans.

In any year, effects to groundwater are expected to be negligible under Alternative 7. A maximum of three whale carcasses would be stored at the Makah Transfer Station during winter/spring hunts and one carcass during summer/fall hunts. With an average harvest of two whales per year over the 10-year waiver period, any risk to groundwater quality under Alternative 7 would be lower than under Alternatives 2, 3, and 6, which each allow for three to five carcasses to be stored at the transfer station per year. Alternative 7 would pose a small but higher risk than Alternatives 4 and 5 (up to one carcass per year) and the No-action Alternative (0).

If the Tribe does not receive authorization to hunt during some or all of the winter/spring hunting seasons, the overall impacts of Alternative 7 on water quality could be lower than estimated here. However, it is difficult to determine the likelihood and magnitude of such a scenario in such a way as to compare it against the other six alternatives. Implementing one of the low abundance thresholds for the ENP stock included in Sub-alternatives 7(a) through (c) may also reduce the impacts on water quality below those analyzed above under Alternative 7 without a threshold. As described below in Subsection 4.4.3.2.1, Change in Abundance and Viability of the ENP Gray Whale Stock, the threshold under Sub-alternative 7(a) is the least likely to be triggered or reduce the number of authorized hunting years over the waiver period of the three sub-alternatives, and, therefore, the least likely to reduce the number of days with hunt-related trips and the number of whales harvested. Sub-alternative 7(c), on the other hand, carries the highest likelihood of being triggered and could reduce the number of authorized hunting years significantly. Therefore, we expect impacts on water quality might be lowest under Sub-alternative 7(c) and highest under Sub-alternative 7(a).

4.3 Marine Habitat and Species

4.3.1 Introduction

This Subsection evaluates the potential for the seven alternatives to affect marine habitat and associated biological resources within the action area. It includes a discussion of the likely ecological

consequences of two possible types of effects that were identified through the internal and public scoping processes (Subsection 1.5.2.1, Marine Habitats and Species): (1) potential direct effects from hunt-related activities, such as disturbance associated with marine vessel traffic or disposition of whale carcasses, and (2) potential indirect effects resulting from the removal or harassment of gray whales from the local ecosystem, such as reduced benthic disturbance by feeding whales and decreased consumption of pelagic and epibenthic prey. Consistent with the description of marine habitat and associated species in Subsection 3.3, Marine Habitat and Dependent Species, this analysis separately examines the potential effects on pelagic and benthic habitats.

4.3.2 Evaluation Criteria

None of the action alternatives has the potential to appreciably affect the physical features and dynamic processes of the pelagic or benthic environments (described in Subsections 3.3.3.1, Pelagic Environment, and 3.3.3.2, Benthic Environment, respectively). The ocean currents, seasonal variability, upwelling, downwelling, eddies, fronts, El Niño Southern Oscillation events, and the Pacific Decadal Oscillation that influence the pelagic environment are large-scale, physical oceanographic and climatic processes that cannot reasonably be expected to be affected by the action alternatives, which involve comparatively small-scale, short-term, localized activities. Similarly, the substrata, features (e.g., submarine canyons), and physical disturbances that make up the benthic environment also are large-scale and cannot reasonably be expected to be affected by the small-scale, short-term, and localized activities associated with the action alternatives.

Consequently, the evaluation of the action alternatives below focuses on the potential direct and indirect effects on the biological resources associated with the pelagic and benthic environments. For both the pelagic and benthic environments, two criteria were used to determine the potential for effects. The first is the amount of physical disturbance associated with conducting a whale hunt (such as vessel traffic or towing a whale), which could have direct effects on the environment. The second is the change in pelagic or benthic communities in the action area, which could result if gray whales are removed from the action area. The following subsections discuss the potential effects in greater detail and how the effects for each alternative may be assessed and differentiated.

4.3.2.1 Pelagic Environment Evaluation Criteria

4.3.2.1.1 Disturbance of Pelagic Species

Hunt-related activities, such as vessel traffic or hauling of whale carcasses, could disturb fish or other pelagic species. This evaluation criterion relates to the potential risk that the action alternatives may affect the distribution and abundance of fish or other pelagic species in the action area. The amount of disturbance and any resulting change in fish distribution or abundance would depend primarily on the

amount, distribution, and timing of hunt-related vessel traffic in the action area. The amount of anticipated vessel traffic would depend on the number of hunts initiated and how many whales could be struck or harvested under a given action alternative. The distribution of vessel traffic would depend on the hunt area and the specific location of pursued whales at the time of a hunt.

4.3.2.1.2 Changes in the Pelagic Community

This evaluation criterion relates to the potential ecological consequences of a whale hunt on the pelagic environment. If the consumption of pelagic prey by gray whales represents a significant factor in determining zooplankton species abundance or plays a significant role in structuring planktonic communities, it is possible that the abundance, species composition, and spatial distribution of pelagic organisms could be altered if whales were harassed in or removed from the action area. The amount of ecological change induced by a whale hunt would depend on the relative change in whale presence and prey consumption, as well as the importance of whale prey consumption relative to oceanographic/climatic processes in determining the dynamics of zooplankton species assemblages in the action area.

4.3.2.2 Benthic Environment Evaluation Criteria

4.3.2.2.1 Disturbance of Benthic Habitat

Potential direct impacts to the benthic habitat from hunting gray whales might result from disturbances associated with increased vessel traffic and disposition of carcasses (relative to the No-action Alternative). Such impacts could include (1) disturbance or damage to eelgrass, surfgrass, kelp beds, or kelp rafts; (2) an increase in the number or generation of kelp rafts; (3) disturbance to nearshore rocky and soft-bottom communities; and (4) disturbance or damage to shellfish resources. Each of these potential impacts is considered under the evaluation criterion for assessing disturbances to the benthic habitat and is described in more detail in the following paragraphs.

Hunt-related activities, such as nearshore vessel traffic and hauling whale carcasses, could result in the disturbance of marine plant or kelp beds at or near landing beaches. This analysis considers the frequency and severity of such hunt-related disturbances relative to the natural levels of physical disturbance in the action area. Additionally, the capacity of these marine plant and macroalgal species for growth and recolonization in response to disturbance is an important consideration. The amount of hunt-related disturbance would depend primarily on the amount of hunt-related vessel traffic in the action area. The amount of vessel traffic that may be expected would depend on the number of hunts initiated and how many whales could be struck or harvested under a given action alternative.

Floating rafts of kelp and associated biota occur within the action area. Kelp rafts are generated by storms and other disturbance events that dislodge kelp holdfasts from their attachment to the

substratum. Although kelp rafts are free-floating and associated with the pelagic environment, they are considered in this analysis as part of the benthic habitat as they are the product of benthos disturbance. They are ecologically important to benthic communities as potential vectors of dispersal for benthic species and as possible sources of organic material upon sinking. Hunt-related activities such as vessel traffic could potentially generate kelp rafts by disturbing stands of kelp. Additionally, kelp rafts are susceptible to damage or disturbance if struck by the propellers of vessels associated with the hunt. Any hunt-related generation or disturbance of kelp rafts would occur in the context of background physical processes affecting the generation and disturbance of kelp rafts in the action area. The amount of hunt-related disturbance would depend primarily on the amount of hunt-related vessel traffic in the action area. The amount of vessel traffic that may be expected would depend upon the number of hunts initiated and the number of whales that could be struck or harvested under a given action alternative.

The hauling and landing of whale carcasses on rocky or soft-bottomed nearshore habitats could result in the disturbance of associated species and communities. This analysis considers the frequency and severity of such hunt-related disturbance relative to background levels of natural disturbance (e.g., storms, wave action, and predation). The amount of hunt-related disturbance would depend primarily on how many whales could be harvested under a given action alternative.

The landing of whale carcasses on beaches with shellfish resources could result in disturbance of these shellfish communities (the potential for hunt-related activities to result in the closure of beaches to shellfish harvest is evaluated in Subsection 4.2, Water Quality). This analysis considers the frequency and severity of such hunt-related disturbance relative to background levels of natural disturbance (e.g., storms, wave action, and predation). The amount of hunt-related disturbance to shellfish communities would depend primarily on how many whales could be harvested under a given action alternative.

4.3.2.2.2 Changes in Disturbance-dependent Benthic Communities

Potential indirect impacts on the benthic habitat from hunting gray whales may occur if benthic-feeding gray whales were harassed in or removed from the ecosystem. Such impacts include changes in the relative level of benthic disturbance because of a decrease in the number of benthic-feeding gray whales and changes in the abundance or distribution of benthic prey species because of a decrease in the quantity of benthic food consumed by gray whales.

If feeding-associated disturbance by benthic-feeding gray whales represented a significant factor in structuring benthic communities, benthic communities could be altered if whales were harassed in or removed from the action area. Background physical processes may include disturbance by storms, wave action, and movement and accumulation of sediments (e.g., turbidity currents). Background biological processes may include seasonality and variability of surface water productivity and delivery

of organic material to the benthic communities. The amount of ecological change induced by a whale hunt would relate to changes in whale presence, as well as the importance of whale prey consumption relative to other physical and biological processes in determining the dynamics of benthic species assemblages in the action area.

This analysis also considers the potential ecological consequences of a whale hunt on the benthic environment. If the consumption of benthic prey by gray whales represents a significant factor in determining species abundance and distribution, the abundance, species composition, and spatial distribution of benthic food items might be altered if whales were removed from or harassed in the action area. The amount of ecological change induced by a whale hunt would relate to changes in whale presence and prey consumption, as well as the importance of whale prey consumption relative to other physical and biological processes in determining the dynamics of benthic species assemblages in the action area.

4.3.3 Evaluation of Alternatives

The following subsections consider the potential for the alternatives to affect pelagic and benthic habitats and associated biological resources in the action area. For each alternative, risks to both pelagic and benthic environments are discussed. The analysis evaluates potential effects resulting from direct disturbance and indirect ecological effects of a whale hunt under a given alternative.

The marine environment of the action area, as noted in Subsection 3.3.1, Introduction, is highly energetic, productive, and variable as a result of the dynamic physical oceanographic processes and the high levels of physical disturbance characteristic of the Washington coast. The abundance, recruitment, distribution, and variation in marine species and communities in the action area strongly reflect the underlying physical environment. When evaluated in the context of this energetic and dynamic environment, evaluation of the alternatives indicates that none of them has the potential to appreciably affect pelagic or benthic habitats or the associated organisms and communities. The following subsections discuss these conclusions in more detail.

4.3.3.1 Alternative 1, No Action

Under Alternative 1, the No-action Alternative, no whale hunt would be permitted, no associated activities (e.g., increased vessel traffic) would be expected to occur, and no whales would be harassed in or removed from the action area. The dynamic processes described in Subsection 3.3.3, Existing Conditions, would be expected to continue in both the pelagic and benthic environments. No direct disturbance resulting in the altered presence or abundance of fish or other pelagic species would be expected, nor would pelagic species or the community experience any indirect ecological consequences

because there would be no hunting activities. Similarly, no direct disturbance would affect marine plant or kelp beds, kelp rafts, nearshore communities, or nearshore shellfish resources, nor would benthic species and communities experience indirect ecological effects.

4.3.3.2 Alternative 2, Tribe's Proposed Action

Whale hunts would be permitted under Alternative 2, resulting in an expected increase in hunt-related vessel traffic over the No-action Alternative, as well as the harassment or removal of whales from the action area. Hunt-related trips would be expected to occur on approximately 60 days per year under Alternative 2. An average of four whales could be harvested per year, with no more than five harvested in a single year. No more than seven whales could be struck per year, and no more than 42 could be struck over a 6-year period. No more than three whales could be struck and lost in any year. Limits on the hunting season (December 1 through May 31) may make it difficult for tribal members to harvest the full number of whales allowed. The hunt area would consist of the coastal portion of the Tribe's U&A.

4.3.3.2.1 Pelagic Environment

Compared to the No-action Alternative, Alternative 2 would likely result in an increased level of direct disturbance because of hunt-related vessel traffic on approximately 60 days per year. These activities and the hauling of an average of four carcasses of harvested whales might disturb fish or other pelagic species in the action area. Any such disturbance would, however, likely be minor (vessels are small and the area is large and highly energetic), local (limited to waters near the activity), and of short duration (minutes to hours). Because any disturbance would be minor, localized, and short-term, it would be unlikely to result in an appreciable change in the presence, distribution, or abundance of fish and other pelagic species in the action area, compared to the No-action Alternative.

This alternative would involve pursuit and hunting of gray whales, and it would likely result in harassment or removal of whales from the action area. As noted above, the potential ecological effect on pelagic species and assemblages of removing whales from the ecosystem would depend on 1) the relative change in whale presence and prey consumption and 2) the relative importance of whale prey consumption in determining the dynamics of zooplankton species assemblages in the action area.

The consumption of pelagic prey by gray whales is not likely a significant factor in structuring pelagic communities relative to the highly variable and energetic oceanographic and climatic processes characteristic of the action area. As discussed in Subsection 3.3.3.1, Pelagic Environment, the physical features and ephemeral, seasonal, interannual, and interdecadal physical oceanographic processes largely control the abundance, distribution, and species composition of pelagic prey in the region. However, even assuming that gray whales do play a substantial role in structuring pelagic communities,

the potential relative change in the number of whales under this and the other action alternatives would be unlikely to result in any appreciable ecological effects. The number of whales allowed to be removed annually represents less than 0.1 percent of the ENP gray whale population, many of which travel close to shore through the action area each year (Subsection 3.4.3.3.2, ENP Seasonal Distribution, Migration, and Movements). Furthermore, the number of whales potentially removed is substantially smaller than the observed levels of interannual variability in whale abundance within the action area. Consequently, any relative change in the quantity of pelagic prey consumed because of removal of whales under Alternative 2 would be negligible and lower than the expected levels of natural variability.

It is possible that hunting under Alternative 2 in the coastal portion of the Tribe's U&A could, over time, cause gray whales to use the area less frequently during the summer feeding period (Subsection 4.4.3.2.4, Change in Numbers of Gray Whales in the Makah U&A and OR-SVI Survey Areas). Given that consumption of pelagic prey by gray whales is not likely a significant factor in structuring pelagic communities, as described above, even this outcome would not affect pelagic communities in the action area.

4.3.3.2.2 Benthic Environment

Compared to the No-action Alternative, an increased level of direct disturbance would probably occur under Alternative 2 because of hunt-related vessel traffic on approximately 60 days and the hauling of an average of four whale carcasses annually. The expected amount of disturbance to eelgrass, surfgrass, kelp beds, and shellfish communities would depend on the specific route of hunt-related vessels, as well as the location of these communities relative to the landing beach for any whale carcasses. The marine plant, macroalgal, and shellfish communities in the action area thrive in a highly energetic and disturbance-prone nearshore environment such that any hunt-related disturbance effects would likely be negligible relative to the high levels of natural background disturbance. Furthermore, the high capacity of these species for growth and recolonization suggests that hunt-related disturbance effects, if any, would be short lived. Similarly, any direct disturbance to kelp rafts would likely be negligible relative to the background physical processes affecting the generation and distribution of kelp rafts in the action area.

As discussed above, in evaluating the potential consequences for the pelagic environment of whale removal, the potential change in the number of whales under this and the other action alternatives would be small relative to the overall whale population and natural levels of variability in whale presence. Consequently, the removal of one to several whales per year would be unlikely to appreciably change background levels of benthic disturbance or the quantity of benthic prey consumed.

Furthermore, the best available information indicates that feeding aggregations (the whales) and feeding areas (the prey) are dynamic, with both small- and large-scale changes over time and space. Gray whales may play a role in structuring benthic and epibenthic communities in the action area, though the relative importance is unclear. Benthic communities are strongly affected by the presence of benthic features (e.g., submarine canyons), physical disturbance processes (such as storms, wave action, and the movement and accumulation of sediments), and ephemeral, seasonal, interannual, and interdecadal physical and biological processes affecting the delivery of organic material from productive surface waters.

Any whales struck and killed but lost would affect the benthic environment by providing "whale fall" microhabitats. This would also be the case for carcasses of any whales harvested and disposed of at sea. As a whale carcass decays on the ocean floor, it provides an ephemeral habitat associated with a unique and diverse invertebrate community. Whale falls occur naturally when individuals die and sink to the sea floor. Under Alternative 2, up to three whales may be struck and lost per year (presumably resulting in whale falls), and up to 18 whales may be struck and lost over a 6-year period. No estimates are available for the annual level of natural mortality that may occur within the action area. Such an estimate would be useful for establishing a background level of whale falls expected to occur naturally in the action area, enabling a comparison with the number of additional whale falls that might be generated under Alternative 2. Compared to the annual level of natural mortality for the ENP gray whale stock as a whole (with a population of some 14,500 and an estimated annual mortality rate of about 2 percent (Punt and Wade 2012), which works out to approximately 290 whales dying per year, most of which likely become whale falls either inside or outside of the action area), the addition of 3 whale falls annually would be minor.

4.3.3.3 Alternative 3, Offshore Hunt

Alternative 3 would include the same limits on total numbers of whales struck and harvested as Alternative 2, but would impose additional restrictions on the mortality of PCFG whales and would prohibit Makah hunters from making an initial strike on a gray whale within 5 miles (8 km) of shore. As under Alternative 2, an increased level of direct disturbance relative to the No-action Alternative would occur under Alternative 3 because of hunt-related vessel traffic on approximately 60 days.

In contrast to Alternative 2, whales struck and lost would be counted toward the annual mortality limit for PCFG whales, potentially reducing the total number of whales that could be harvested in some years. Under some scenarios, it is possible that hunting activities for a given year could be curtailed before any whales are successfully harvested (Subsection 4.1.3, Alternative 3). Compared to Alternative 2, therefore, it is less likely that the Tribe would be able to harvest and haul to shore an

average of four whales per year under Alternative 3. The reduced likelihood that the full number of whales would be towed to shore would be expected to result in a smaller increase in effects relative to the No-action Alternative, compared to Alternative 2.

4.3.3.3.1 Pelagic Environment

The prohibition on making an initial strike within 5 miles (8 km) of shore would likely result in more hunting effort taking place farther off shore under Alternative 3 than under the other action alternatives. As a result, hunt-related vessel traffic could spend more time in the pelagic environment, with an attendant increase in the potential for disturbance of pelagic species compared to the No-action Alternative. Similar to Alternative 2, however, the risk of direct disturbance of fish and other pelagic species under Alternative 3 would be minor, localized, and of short duration. Similarly, for the reasons described under Alternative 2, any removal of whales under Alternative 3 would not likely result in indirect ecological effects on pelagic communities. Thus, compared to the No-action Alternative, Alternative 3 would not be likely to result in an appreciable change in the presence, distribution, or abundance of fish and other pelagic species in the action area.

4.3.3.3.2 Benthic Environment

Similar to Alternative 2, the risk of direct disturbance of benthic marine plant, macroalgal, shellfish, and kelp raft communities under this alternative would be negligible relative to the high levels of background disturbance and the strong capacity of these species for growth and recolonization. Similarly, for the reasons described under Alternative 2, any removal of whales under Alternative 3 would not be likely to result in indirect ecological effects on benthic communities. Thus, Alternative 3 would be unlikely to result in an appreciable change in benthic communities compared to the No-action Alternative.

4.3.3.4 Alternative 4, Summer/Fall Hunt

Under Alternative 4, the hunting season would extend from June 1 through November 30 instead of December through May. The maximum number of whales harvested under current conditions would be one ENP male whale every other year (Table 4-7); because any whales struck and lost would count against the PCFG limit, the maximum number of whales struck and lost would also be one every other year. Based on the expectation that locating and striking a known ENP male would take no more than 7 days (Subsection 4.1.4, Alternative 4), vessel traffic associated with hunt-related trips under Alternative 4 would be likely to occur on approximately 7 days every other year under current conditions. The effects of Alternative 4 on marine habitat and species would, therefore, be greater than the No-action Alternative but less than all other action alternatives, based on the number of hunt days and the number of whales killed.

4.3.3.4.1 Pelagic Environment

Compared to the No-action Alternative (under which there would be no hunt-related vessel traffic), Alternative 4 would result in an increased risk of direct disturbance of fish and other pelagic species. The increase would, however, be smaller than under any of the other action alternatives because hunt-related vessel traffic would be likely to occur on 7 days every other year, compared to approximately 60 days under Alternatives 2 and 3. Similar to Alternative 2, this alternative would likely result in minor, local, and short-term effects on pelagic communities through direct disturbance. Similarly, for the reasons described under Alternative 2, any removal of whales under Alternative 4 would not be likely to result in indirect ecological effects on pelagic communities. Thus, compared to the No-action Alternative, Alternative 4 would not be likely to result in an appreciable change in the presence, distribution, or abundance of fish and other pelagic species in the action area.

4.3.3.4.2 Benthic Environment

Similar to Alternative 2, the risk of direct disturbance of benthic marine plant, macroalgal, shellfish, and kelp raft communities under this alternative would be negligible relative to the high levels of background disturbance and the strong capacity of these species for growth and recolonization. Similarly, for the reasons described under Alternative 2, any removal of whales under Alternative 4 is not likely to result in indirect ecological effects on benthic communities. Thus, Alternative 4 would be unlikely to result in an appreciable change in benthic communities compared to the No-action Alternative.

4.3.3.5 Alternative 5, Split-season Hunt

Under Alternative 5, the hunting season would be 3 weeks in December and 3 weeks in May, in contrast to the 6-month-long hunting seasons under the other action alternatives. While up to five whales could be killed in a year, the landing of a single PCFG whale, or the striking and losing of a single whale, would end the hunt for any given year. Based on the length of the hunting season, vessel traffic associated with hunt-related trips under Alternative 5 would likely occur on approximately 22 days per year. This could decrease to 0 days in years in which the hunt is on hiatus to allow the PCFG mortality limit to re-set at one whale. Therefore, effects on marine habitat and species under Alternative 5 would likely be less than those described under Alternatives 2 and 3 based on vessel traffic associated with hunt-related trips and the number of whales harvests but slightly higher than Alternative 4.

4.3.3.5.1 Pelagic Environment

Compared to the No-action Alternative (under which there would be no hunt-related vessel traffic), Alternative 5 would result in an increased risk of direct disturbance of fish and other pelagic species. The increase would be greater than under Alternative 4 (which would be expected to result in 7 days of

hunt-related vessel traffic every other year) but less than under Alternatives 2 and 3 (which would be expected to result in approximately 60 days of hunt-related vessel traffic per year). Any direct disturbance effects under this alternative on fish and other pelagic species would likely be local and short-term, for the same reasons as described under Alternative 2. Similarly, for the reasons described under Alternative 2, any removal of whales under Alternative 5 would not be likely to result in indirect ecological effects on pelagic communities. Because Alternative 5 would be expected to result in fewer hunting expeditions and fewer whales removed from the action area than Alternatives 2 or 3, it would have less potential for effects than those alternatives. Thus, Alternative 5 would be unlikely to result in appreciable changes in the presence, distribution, or abundance of fish and other pelagic species in the action area compared to the No-action Alternative.

4.3.3.5.2 Benthic Environment

Any direct disturbance effects under this alternative on benthic marine plant, macroalgal, shellfish, and kelp raft communities would be negligible relative to the high levels of background disturbance and the strong capacity of these species for growth and recolonization, as described under Alternative 2. Similarly, for the reasons described under Alternative 2, any removal of whales under Alternative 5 is not likely to result in indirect ecological effects on pelagic communities. Because Alternative 5 would result in fewer hunting expeditions and fewer whales removed from the action area than Alternatives 2 and 3, it would have less potential for effects than these alternatives. Thus, Alternative 5 would probably not result in an appreciable change in benthic communities compared to the No-action Alternative.

4.3.3.6 Alternative 6, Different Limits on Strikes and PCFG, and Limited Duration of Regulations and Permits

Alternative 6 would have the same conditions as Alternative 2 regarding the hunt area, season, and methods and would, therefore, result in the same number of days (60) with hunt-related trips. Alternative 6 would include greater restrictions than Alternatives 2, 3, and 5 on the maximum number of whales that could be struck, harvested, and struck and lost per year and per 2 years, resulting in a maximum of 3.5 whales killed (either harvested or struck and lost) per year on average. Therefore, effects on marine habitat and species under Alternative 6 would likely be the same as those described under Alternatives 2 and 3, except that the number of whales harvested or struck and lost would be smaller. Vessel traffic-based effects on marine habitat and species under Alternative 6 would be slightly higher than Alternatives 4 and 5based on the number of expected hunt days per year. Also, under Alternative 6, the waiver of the MMPA take moratorium and implementing regulations would lapse after 10 years, and it is not possible to predict whether they would be replaced with a new waiver

and implementing regulations or what the terms of any new waiver and regulations would be. Therefore, the analysis for Alternative 6 considers hunt activities lasting only over a 10-year period.

4.3.3.6.1 Pelagic Environment

Compared to the No-action Alternative (under which there would be no hunt-related vessel traffic), Alternative 6 would result in an increased risk of direct disturbance of fish and other pelagic species. Based on the likely number of days with hunt-related trips, the increase would be similar to that expected under Alternative 2. As described under Alternative 2, the risk of direct disturbance of fish and other pelagic species under this alternative would be minor, localized, and of short duration. Similarly, for the reasons described under Alternative 2, any removal of whales under Alternative 6 would not be likely to result in indirect ecological effects on pelagic communities. Thus, compared to the No-action Alternative, Alternative 6 would not be likely to result in an appreciable change in the presence, distribution, or abundance of fish and other pelagic species in the action area.

4.3.3.6.2 Benthic Environment

Similar to Alternative 2, the risk of direct disturbance of benthic marine plant, macroalgal, shellfish, and kelp raft communities under this alternative would be negligible relative to the high levels of background disturbance and the strong capacity of these species for growth and recolonization. Similarly, for the reasons described under Alternative 2, any removal of whales under Alternative 6 would be unlikely to result in indirect ecological effects on benthic communities. Thus, Alternative 6 would probably not result in an appreciable change in benthic communities compared to current conditions under the No-action Alternative.

4.3.3.7 Alternative 7, Composite alternative – Preferred

Alternative 7 combines various elements from Alternatives 2 through 6. While the proposed hunt method, target species, age and reproductive status restrictions, and other environmental protection measures (Subsection 2.3.2.2.12) are the same as Alternative 2, under Alternative 7 there would be both a winter/spring hunt and a summer/fall hunt in alternating years. During winter/spring hunts, a maximum of three whales may be struck regardless of whether or not they are landed. During summer/fall hunts, a maximum of two whales may be struck but only if the first whale is lost (i.e., struck but not landed). Similar to Alternative 6, the waiver would expire after 10 years, so the analysis for Alternative 7 considers effects only over a 10-year period.

To compare the overall impact of hunt-related trips on pelagic and benthic environments under Alternative 7 to the impacts of the other six alternatives, we use an annual average number of 37 days with hunt-related trips (300 winter/spring days plus 70 summer/fall days divided by the 10-year span of the waiver period). Alternative 7 would, therefore, result in a smaller risk of disturbance than

Alternatives 2, 3, and 6 (each with 60 days of hunt-related trips per year). However, Alternative 7 would result in a greater risk than the No-action Alternative (0 days) as well as Alternatives 4 and 5 (an average of 3.5 days and 22 days of hunt-related trips, respectively). The overall impact of whale falls/carcass disposal under Alternative 7 (up to 2.5 whales per year on average) would also be intermediate to the other alternatives, i.e., lower than the three to five whales under Alternatives 2, 3, and 6, and slightly higher than the zero to one whales under the No-action Alternative, Alternative 4, and Alternative 5. If the Tribe does not receive authorization to hunt during some or all of the winter/spring hunting seasons, the overall impacts of Alternative 7 on the marine habitat could be lower than estimated here; however, it is difficult to determine the likelihood and magnitude of such a scenario in such a way as to compare it against the other action alternatives.

Implementing a low abundance threshold for the ENP stock may also reduce impacts on the marine habitat and species below those already analyzed under Alternative 7 without a threshold. As described below in Subsection 4.4.3.7.1, Change in Abundance and Viability of the ENP Gray Whale Stock, the threshold under Sub-alternative 7(c) carries the highest likelihood of reducing the number of authorized hunting years and, therefore, the annual average number of days with hunt-related trips and the number of whales harvested over the waiver period of the three sub-alternatives. Sub-alternative 7(a), on the other hand, is most likely to allow hunting to occur during all 10 years of the proposed waiver period. As such, of the three sub-alternatives, 7(c) could result in the lowest potential impact to the marine habitat while 7(a) could result in the greatest potential impact.

4.3.3.7.1 Pelagic Environment

As with the other action alternatives, Alternative 7 would result in an increased risk of direct disturbance of fish and other pelagic species compared to the No-action Alternative. During winter/spring hunts, there would be an estimated 60 days of hunt-related trips and the hauling of up to three carcasses of harvested whales which might disturb fish or other pelagic species in the action area. During summer/fall hunts, there would be 7-14 days with hunt-related trips and the hauling of one harvested whale carcass. Any such disturbance would, however, likely be minor (vessels are small and the area is large and highly energetic), local (limited to waters near the activity), and of short duration (minutes to hours). Because any disturbance would be minor, localized, and short-term, it would be unlikely to result in an appreciable change in the presence, distribution, or abundance of fish and other pelagic species in the action area, compared to the No-action Alternative.

Also, as noted in Subsection 3.3.3.1, the consumption of pelagic prey by gray whales is not likely a significant factor in structuring pelagic communities relative to the highly variable and energetic oceanographic and climatic processes characteristic of the action area. The physical features and

ephemeral, seasonal, interannual, and interdecadal physical oceanographic processes largely control the abundance, distribution, and species composition of pelagic prey in the region. However, even assuming that gray whales do play a substantial role in structuring pelagic communities, the potential relative change in the number of whales under this and the other action alternatives would be unlikely to result in any appreciable ecological effects. The number of whales allowed to be removed under Alternative 7 represents far less than 0.1% of the ENP gray whale population on an annual basis, and less than 0.2% over the 10-year waiver period (based on the current abundance estimate). Furthermore, the number of whales potentially removed is substantially smaller than the observed levels of interannual variability in whale abundance within the action area. Consequently, any relative change in the quantity of pelagic prey consumed because of removal of whales under Alternative 7 would be negligible and lower than the expected levels of natural variability.

Hunting under Alternative 7 may remove gray whales from the Tribe's U&A during the summer feeding period. Given that consumption of pelagic prey by gray whales is not likely a significant factor in structuring pelagic communities, as described above, even this outcome would not affect pelagic communities in the action area.

4.3.3.7.2 Benthic Environment

The expected amount of disturbance to the benthic environment—especially eelgrass, surfgrass, kelp beds, and shellfish communities—would depend on the specific route of hunt-related vessels, as well as the location of these communities relative to the landing beach for any whale carcasses. Since the marine plant, macroalgal, and shellfish communities in the action area thrive in a highly energetic and disturbance-prone nearshore environment, any hunt-related disturbance effects would likely be negligible relative to the high levels of natural background disturbance. Furthermore, the high capacity of these species for growth and recolonization suggests that hunt-related disturbance effects, if any, would be short-lived. Similarly, any direct disturbance to kelp rafts would likely be negligible relative to the background physical processes affecting the generation and distribution of kelp rafts in the action area.

As discussed above, in evaluating the potential consequences for the pelagic environment of whale removal, the potential change in the number of whales under this and the other action alternatives would be small relative to the overall whale population and natural levels of variability in whale presence. Consequently, the removal of one to several whales per year would likely not appreciably change background levels of benthic disturbance or the quantity of benthic prey consumed. Furthermore, the best available information indicates that feeding aggregations (the whales) and feeding areas (the prey) are dynamic, with both small- and large-scale changes over time and space.

Gray whales may play a role in structuring benthic and epibenthic communities in the action area, though the relative importance is unclear. Benthic communities are strongly affected by the presence of benthic features (e.g., submarine canyons), physical disturbance processes (such as storms, wave action, and the movement and accumulation of sediments), and ephemeral, seasonal, interannual, and interdecadal physical and biological processes affecting the delivery of organic material from productive surface waters.

Any whales struck and killed but lost would affect the benthic environment by providing "whale fall" microhabitats. This would also be the case for carcasses of any whales harvested and disposed of at sea. As a whale carcass decays on the ocean floor, it provides an ephemeral habitat associated with a unique and diverse invertebrate community. Whale falls occur naturally when individuals die and sink to the sea floor. Under Alternative 7, up to two or three whales may be struck and lost per year (presumably resulting in whale falls). No estimates are available for the annual level of natural mortality that may occur within the action area. Such an estimate would be useful for establishing a background level of whale falls expected to occur naturally in the action area, enabling a comparison with the number of additional whale falls that might be generated under the action alternatives. Compared to the annual level of natural mortality for the ENP gray whale stock as a whole (with an estimated annual mortality rate of about 2% (Punt and Wade 2012), which works out to approximately 290 whales dying per year, most of which likely become whale falls either inside or outside of the action area), the addition of two to three whale falls annually under Alternative 7 would be minor.

4.4 Gray Whales

4.4.1 Introduction

This section addresses the potential for the alternatives to affect gray whales across a range of biological scales, from individual whales to entire stocks. The analysis considers potential effects on abundance and viability of the two recognized gray whale stocks—ENP and WNP—and further analyzes potential effects to the ENP stock at the scale of gray whales in the PCFG range as well as the Makah U&A and OR-SVI survey areas within the PCFG range. Although the PCFG is not considered a "population stock" under the MMPA, our analysis also considers potential effects on its abundance and viability (biological concepts normally associated with a discrete stock) because: (1) the Tribe has proposed a management scheme that manages separately for PCFG whales (for example, by setting an allowable bycatch limit); (2) the IWC has concluded it is "plausible" that the PCFG is a demographically distinct feeding aggregation; and (3) we have concluded that the PCFG "may warrant consideration" in the future as a stock under the MMPA.

For whales that have been documented using the Makah U&A and OR-SVI areas, our analysis considers potential effects on the numbers of whales that use those areas, for reasons described in Subsection 4.4.2.4, Change in Numbers of Gray Whales in the Makah U&A and OR-SVI Areas. Our analysis does not consider the viability of whales using these survey areas because our stock assessment reports (e.g., Carretta et al. 2023) have not suggested that these smaller units may be stocks, the genetic information does not indicate that there could be stock structure below the PCFG, and monitoring of movements of photographically identified whales suggest that they use a larger feeding area than the Makah U&A and OR-SVI (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements).

For effects on individual whales, the analysis considers time to death and hunting efficiency (the ratio of harvested to struck-and-lost whales) associated with the alternative methods of striking and killing whales. These methods are limited to what NMFS considers reasonable options for striking and killing whales (Subsection 2.4.6, Employ Different Hunting Methods), including using either a toggle-point harpoon as the primary striking method and .50 caliber rifle (or .577 caliber) as the killing method or using an explosive projectile as the striking and killing method. Alternative vessels to position the harpooner are also considered, with a wooden canoe being used in Alternatives 2, 4, 5, 6, and 7 and a motorized vessel being used in Alternative 3.

Section 5, Cumulative Effects, considers whether the effects to gray whales that might result from implementing any of the alternatives would be likely to have cumulative effects in the context of past actions, other contemporaneous actions, or reasonably foreseeable future actions that may affect gray whales, such as other human or natural sources of mortality, potential development in the action area, or global climate change.

4.4.2 Evaluation Criteria

Five criteria were used to determine the potential for effects to gray whales under the alternatives: (1) change in abundance and viability of the ENP gray whale stock; (2) change in abundance and viability of the WNP gray whale stock; (3) change in abundance and viability of PCFG whales; (4) change in numbers of gray whales that use the Makah U&A and OR-SVI survey areas; and (5) welfare of individual whales. The following sections discuss risks to gray whales at each of these scales and how the effects of the alternatives may be assessed and differentiated.

4.4.2.1 Change in Abundance and Viability of the ENP Gray Whale Stock

As described in Subsection 1.2.4.1.3, IWC Aboriginal Subsistence Whaling, the catch limit for the ENP gray whale stock set by the IWC for 2019 through 2025 would remain the same under all seven

alternatives—980 whales over 7 years (averaging 140 whales per year), with a strike limit of 140 whales in any one year. The difference among the alternatives is how much of that catch limit would be allocated to the Makah Tribe. Because it is likely the United States would transfer any unused share of the catch limit to Russia (Subsection 4.1.1, Alternative 1) and all seven alternatives contemplate the same overall catch limit for the stock, all of the alternatives would likely have the same effect on the abundance and viability of the ENP gray whale stock as a whole.

Hunt-related stress on gray whales (particularly pursuit and unsuccessful harpoon attempts) under the six action alternatives could differ from the No-action Alternative if a Makah hunt resulted in a greater level of indirect mortality or reduced reproduction than a Chukotkan hunt. Indirect mortality would result if stress caused by hunting increased the whales' susceptibility to predation or disease and ultimately increased the level of mortality beyond whales directly killed during hunting (Subsection 3.4.3.5.2, Whale Response to Being Pursued). Gray whales being pursued by whale-watching vessels have been observed to change course and alter swimming speed and respiratory patterns, potentially indicating stress (see Subsections 3.4.3.6.5, Offshore Activities and Underwater Noise and 3.4.3.6.6, Vessel Interactions).

As described above, if no harvest is allocated to the Makah Tribe, the entire IWC catch limit of 980 gray whales over 7 years would likely be available for harvest by the Chukotka Natives of the Russian Federation. No information is available on the proportion of whales approached and subjected to unsuccessful harpoon attempts in the Chukotkan hunt. Thus, it is likely that the harvest limit of 140 whales would occur under two possible scenarios. Under the first scenario, the quota would be transferred, and the Chukotkan Natives would harvest a maximum of 140 whales per year while the Makah would not harvest whales (i.e., the No-action Alternative). Under the second scenario, the Chukotkan Natives would harvest a maximum of 135 whales per year while the Makah would harvest a maximum of 5 whales per year (the most the Makah can harvest under any of the action alternatives). If the quota is not transferred (which is considered unlikely), the harvest limit would be up to 135 whales harvested by Chukotkan Natives.

Given that we expect the quota would be transferred and the number of whales harvested would be the same under the two scenarios, it is likely that any stress-related impacts would be similar regardless of whether the Makah or the Chukotkan hunters harvested the five whales. While it is possible that, given the Chukotkan hunters' experience, there would be fewer unsuccessful harpoon attempts and approaches on individual whales in a Chukotkan hunt (which could reduce stress-related impacts), these differences are likely to be negligible given that over 96 percent of the whales would be harvested by Chukotkan Natives under either scenario. That is, only a small percentage (approximately 3.5) of the

harvest differs between the two scenarios. Thus, it is likely that the difference in stress-related impacts between the alternatives is negligible. If the Makah allocation is harvested by neither the Makah nor the Chukotka Natives (e.g., if the quota is not transferred), the difference would be seven fewer whales struck per year (per the Tribe's proposal), which is less than 6 percent of the average number of ENP gray whales allocated for harvest by the Chukotkans. Thus, the difference among the alternatives in stress-related impacts is likely to be negligible, regardless of whether or not a transfer of quota would occur under the No Action alternative.

The overall viability of a marine mammal stock that exhibits different life history traits, such as different feeding strategies, could be affected by the loss of components of the stock that exhibit such traits. In the case of ENP gray whales, it is possible that the viability of the stock as a whole depends on the existence and persistence of different feeding aggregations. However, sighting data and diet studies indicate that ENP gray whales, including PCFG whales, have the ability to switch feeding areas over time (Subsection 3.4.3.1.4, Feeding Ecology and Role in the Marine Ecosystem), suggesting that the loss of a feeding aggregation such as the PCFG may not affect the viability of the overall ENP stock. This analysis considers the potential for actions to affect PCFG whales, and that analysis is one component of the analysis of effects to viability of the ENP stock.

4.4.2.2 Change in Abundance and Viability of the WNP Gray Whale Stock

The WNP gray whale stock is not targeted for harvest under any of the alternatives. As described in Subsection 3.4.3.2, Western North Pacific (WNP) Gray Whales, the IWC has not established a catch limit for WNP gray whales, and these whales are not considered in the catch limit established for ENP gray whales (see above). The most recent population assessment of WNP gray whales (Cooke et al. 2017) estimates that there are approximately 290 individuals (excluding calves) in the WNP stock (with a 90 percent confidence interval of 271 to 311 animals), with the abundance increasing at annual rates of 2-5% during recent years (Cooke 2018a).

As described in Subsection 3.4.3.2.1, WNP Seasonal Distribution, Migration, and Movements, very little is known about the migratory routes and wintering areas of WNP gray whales. However, recent research has discovered 60 cases where whales identified from the WNP have also been sighted in the ENP. This represents approximately 21 percent of the WNP gray whale population (Cooke et al. 2017). Cooke et al. (2019) estimated that 45 to 80 percent of Sakhalin gray whales migrate to the ENP in the winter. The sighting data available on WNP migrations and movements suggest that whales from this stock could be encountered in the coastal portion of the Makah U&A during the hunting season proposed by the Tribe under Alternative 2, perhaps with the exception of May 10 to 31 and December 1 to 21, as WNP gray whales have not been sighted in the area during those times. The lack of WNP

whale sightings during these periods, despite active gray whale surveys occurring in May within and adjacent to the Makah U&A, indicate it is unlikely these whales would be encountered by Makah hunters during this timeframe. For all but one of the alternatives (Alternative 4, which was developed to completely avoid times when a WNP whale might be present), we estimate the likelihood of hunters killing a WNP gray whale if the maximum number of strikes were to occur and consider the potential implications on the abundance and viability of the WNP stock as a whole.

4.4.2.3 Change in Abundance and Viability of PCFG Whales

Whales in the PCFG are relevant to our analysis because the IWC considers it plausible that they are a demographically distinct feeding group using a unique summer range and NMFS has determined that the PCFG may warrant consideration as a separate stock in the future. The PCFG is also relevant to the Makah's proposal (Alternative 2) because the Tribe proposes to set an allowable bycatch level that would apply to any whale identified in the PCFG seasonal range (not just whales seen in 2 or more years). Two alternatives (Alternative 4 and 7) include hunting regulations that would specifically target whales in the PCFG seasonal range (i.e., whales in the PCFG area when PCFG whales are present) to avoid impacts to WNP whales. The remaining action alternatives would seek to avoid mortality of PCFG whales through time and area restrictions, or to regulate impacts to PCFG whales through mortality/strike limits.

As noted in Subsection 4.1, Introduction, all seven alternatives (including the No-action Alternative) are likely to result in the same level of harvest from the ENP gray whale stock as a whole because of the likely transfer of any unused share of the catch limit to Russia. It is unlikely that PCFG whales would be present in the area of the Chukotka hunt and thus killed if the U.S. share of the catch limit was transferred.

The alternatives vary in the number of PCFG whales that might be affected by hunting. Under Alternative 1, no PCFG whales would be hunted in the Makah U&A. Under current conditions, Alternative 2 would have the greatest effect because it might result in a maximum of five PCFG whales killed per year (Subsection 4.1.2.3), or 50 whales over 10 years. Alternative 3 poses the next highest risk to PCFG whales, with a maximum potential mortality of four PCFG whales killed per year (Subsection 4.1.3.3), followed by Alternative 6 with a maximum potential mortality of 3.5 PCFG whales per year (Subsection 4.1.6.3), or 40 and 35 whales respectively over 10 years. Alternative 4 and Alternative 5 pose the lowest risk to PCFG whales, with an annual mortality limit of 0.76 and 0.35 respectively. Under these alternatives, PCFG mortality limits are allowed to accrue over consecutive years. Therefore, one PCFG whale may be killed every other year under Alternative 4 (Subsection 4.1.4.3) and one may be killed every third year under Alternative 5 (Subsection 4.1.5.3). This

represents up to five PCFG whales killed over 10 years under Alternative 4 and up to four PCFG whales killed over 10 years under Alternative 5, if one is struck and lost. Alternative 7 does not set an annual mortality limit for PCFG whales but does limit total mortality for PCFG whales over the course of the 10-year waiver period to 16 whales, up to 8 of which may be females. Under current conditions, we expect the Tribe might kill an average of 1.4 PCFG whales per year if all strikes are utilized. In addition, Alternatives 2 to 7 vary in (1) the number of whales that may be struck and lost during hunting (we assume that whales that are struck will die), (2) the mortality limits on PCFG whales and how struck and lost whales would be allocated towards those limits, and (3) the timing and location of hunting. These variations may have different effects on the abundance of PCFG whales.

Subsection 3.4.3.4.3, PCFG Abundance and Trends describes the abundance of PCFG whales. During June 1 through November 30, for 1996 to 2019, 888 unique whales were observed in the PCFG range at least once. Table 3-8 shows the numbers of unique whales observed in the PCFG survey areas each year from 1999 to 2020 (158 whales on average), the number that are newly seen (34 whales on average), and how many of those newly seen whales were seen in a subsequent year (14 whales on average[10]). As described in Subsection 3.4.3.4.3, PCFG Abundance and Trends, the numbers of newly seen whales each year are variable (ranging from 8 to 71 whales) and only a rough approximation of the number of whales that are actually new to the PCFG each year for two reasons: there are likely more whales present each year than are photographed and identified, and it is likely that some whales were present in a previous year but were not photographed and identified. On average, 41 percent of the newly seen whales in the PCFG seasonal range were subsequently seen again and thought to have recruited into the PCFG (Table 3-8). This information demonstrates that many new whales are seen each year in the PCFG seasonal range, and of these, variable but large numbers of whales are seen again. Similarly, variable but large numbers of whales are never seen again in the PCFG seasonal range.

In any given year in which PCFG whales were killed under Alternatives 2 through 7, the total abundance of PCFG whales would be reduced by the number of whales killed (either harvested or struck and lost). Over time, an ongoing hunt could reduce the abundance of PCFG whales, compared to the No-action Alternative. The extent to which a hunt would reduce abundance over time would depend on the number of PCFG whales killed and the rate at which new recruits would replace killed whales. As described in Subsection 3.4.3.4.1, PCFG Population Structure, new animals enter the PCFG as calves born to PCFG mothers (internal recruitment) or as non-calf immigrants (external recruitment).

[10] For this estimate, we exclude 2020 because whales newly seen in that year have not had a chance to be re-sighted.

Whales are identified as calves when they are accompanied by their mother. Once the calf is weaned it may not be recognized as a calf. During the years 2008 to 2017, there were 12.3 new recruits on average annually, of which 7.9 were not identified as calves and 4.4 were identified as calves (Calambokidis et al. 2019). The calf proportion could possibly be higher because some of the new non-calf whales may have entered the PCFG earlier as a calf and were not seen. Regardless of year-to-year variability in both internal and external recruits, alternatives that remove fewer whales are less likely to affect PCFG abundance in subsequent years because there are fewer whales to replace.

With respect to viability of the PCFG, a reduction in abundance of PCFG whales over time could decrease the likelihood that the PCFG is viable, compared to the No-action Alternative. As described in Subsection 3.4.3.4.4, PCFG Status, Carrying Capacity, and Related Estimates [IWC Implementation Review of PCFG Gray Whales], in 2012 the IWC's Scientific Committee evaluated the Makah hunt proposal (Alternative 2) using various versions of the proposal as candidate Strike Limit Algorithms (SLAs) and assuming a consistent level of non-hunting human-caused mortality. The analysis also incorporated 33 evaluation trials and 22 robustness trials (including one where harvests were strongly female-biased). In testing these and other SLA variants, the Scientific Committee did not reference the PCFG's viability per se but did draw conclusions about the PCFG's status with respect to carrying capacity (Subsection 3.4.3.4.4, PCFG Status, Carrying Capacity, and Related Estimates).

The key management and conservation objectives in the IWC's assessment of aboriginal hunt requests includes ensuring they (1) do not seriously increase risks of extinction (highest priority), (2) enable hunts "in perpetuity," and (3) maintain stocks at the highest net recruitment level (and if below that, ensure they move towards it). The SLA variants are tested using a 100-year time horizon, so it is reasonable to conclude that when test results meet the IWC's conservation objectives for a group of whales, the number of strikes analyzed would not be expected to compromise the group's long-term viability. Therefore, the Scientific Committee's conclusions can be interpreted to mean that the Tribe could hunt and PCFG whales would be viable in perpetuity as long as the bycatch formula tested by the IWC is used to limit the strikes on PCFG whales (including struck and lost whales in May) and annual monitoring is conducted to assess the proportion of PCFG whales available to Makah hunters.

In the 2020 Implementation Review, the Scientific Committee received updated abundance estimates for the PCFG through 2017, extending the time series that had been previously considered. The Scientific Committee agreed that the additional years of data did not alter their existing advice "with respect to the suitability of the either the Gray Whale SLA or the Makah Management Plan for the provision of advice on the Chukotkan and proposed Makah hunts" (IWC 2021b). In 2021, the Scientific Committee also reviewed the circumstances of the current unusual mortality event (UME)

and concluded that it fell within the testing parameters for the SLA (Givens and Weller 2021). In 2023, the Scientific Committee reviewed new information on ENP gray whale abundance and stock structure and concluded that the SLA and Makah Management Plan are robust to the current UME as well as future mortality events (Punt et al. 2023, IWC 2023a).

Based on current conditions, the Alternative 2 formula for setting a PCFG bycatch level yields a bycatch limit of 3.0 PCFG whales per year, which is greater than the likely number of PCFG whales that might be killed under any of the other action alternatives (0.35 to 4 whales per year),. Other action alternatives would set a bycatch limit (Alternative 2) or mortality limit (Alternatives 3 through 6) for the PCFG using a formula that includes minimum abundance, and as such, the limit may change over time if the abundance of PCFG whales changes. By contrast, Alternative 7 has a static PCFG strike/mortality limit, but a hunt would be prohibited if the PCFG abundance and/or minimum abundance reached a low threshold.

4.4.2.4 Change in Numbers of Gray Whales Using the Makah U&A and OR-SVI Areas

This analysis also considers effects on gray whales that have been sighted in two areas that are subsets of the survey areas in the PCFG range: (1) the Makah U&A, which includes the northern Washington coast and Strait of Juan de Fuca survey areas, and (2) the OR-SVI survey area, which includes the Makah U&A as well as adjacent coastal survey areas from Oregon to southern Vancouver Island (including the Strait of Juan de Fuca but excluding interior waters of Puget Sound). As directed by the court in *Anderson v. Evans* (2004) and described in Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements, this analysis considers likely effects of the alternatives on the number of gray whales that may be present during the summer period in these survey areas as a way to evaluate local effects. The areas chosen do not necessarily correspond to areas that are biologically meaningful to individual whales or groups of whales, but they are nevertheless used to analyze potential local effects because of their overlap with the proposed hunt area.

Although all of the action alternatives restrict hunting to the coastal portion of the Makah U&A, the analysis of all of the alternatives considers gray whale numbers in both portions (coastal and Strait of Juan de Fuca) of the Makah U&A. This is because of the overlap of whales identified in both areas. If there were a decrease in the number of whales using the coastal portion of the Makah U&A under alternatives that limit hunting to that area, it could also result in a decrease in the number of whales using the Strait of Juan de Fuca.

In addition to the Makah U&A, this analysis also focuses on the OR-SVI survey area. Calambokidis et al. (2004a) recommended using the OR-SVI area as a logical and reasonable management area for considering impacts of gray whale harvests in the Makah U&A (an area within the OR-SVI area)

because of the relatively high rates of interchange. Over 60 percent of whales seen in the OR-SVI survey area are also seen in the northern Washington coast/Strait of Juan de Fuca survey areas (Makah U&A), compared to about 38 percent of whales seen in the PCFG also being seen in the northern Washington coast/Strait of Juan de Fuca survey areas (Makah U&A) (Calambokidis et al. 2019) (Subsection 3.4.3.4.1, PCFG Population Structure).

There are at least two different ways to consider the number of whales using the Makah U&A and OR-SVI survey areas during the summer feeding period: (1) the total number of animals in a single summer feeding period of June through November (which includes PCFG and non-PCFG whales), and (2) the number of animals that regularly use the area during the summer feeding period (i.e. PCFG whales). The first analysis would emphasize the role whales play in the area (for aesthetic, economic, marine habitat, or other values) and how changes in the total number of whales might affect that role. The second analysis would emphasize the whales as a group and the effects of alternative actions on the numbers in that group.[11] For either analysis, a quantitative approach is only possible using the number of identified whales. As described in Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements, it is almost certain that more whales are present in any year than are photographed and identified. Because the number of whales identified is a minimum estimate of the number present, using it overestimates impacts, which is appropriate for a conservative analysis of the potential effects on the environment of alternative actions. For additional context, we also compare the likely number of whales killed under each alternative to the most recent minimum abundance estimate for whales seen in the OR-SVI survey region (Harris et al. 2022). Although an abundance estimate is calculated for the Makah U&A survey region, Calambokidis et al. (2014) has cautioned against doing so based on its small size and sighting data demonstrating that most whales disperse across a much larger area (Subsection 3.4.3.4.3, PCFG Abundance and Trends, Estimating Numbers of Whales for Subregions Within the PCFG Range).

This portion of the analysis considers the potential change in numbers of gray whales using these local survey areas that might result if PCFG whales are killed during hunting (either harvested or struck and lost). Additional stress-related impacts resulting from pursuit or unsuccessful harpoon attempts are possible (Subsection 4.4.2.1, Change in Abundance and Viability of the ENP Gray Whale Stock), but

[11] A further layer of detail in the first analysis would be to estimate a total number of "whale days," because some whales may spend more time in a given area than others. A further layer of detail in the second analysis would be to assign some type of weighting based on the "value" a whale has depending on how many years it had visited an area or how much time it had spent in a particular area. In both cases, the survey data are not sufficiently detailed or complete to support such estimates. Even with additional survey effort, the required level of detail and completeness would be nearly impossible to obtain given the whales' mobility, the expansiveness of the area, and practical limitations on the surveyors' viewing range and timing (e.g., lack of nighttime surveys).

no information is available or could reasonably be obtained that would support an estimate of stress-related impacts on PCFG whale abundance. While stress-related impacts on abundance cannot be estimated, there is information available to qualitatively assess these impacts. Non-lethal hunt activities, particularly approaches, are not likely to have a significantly different effect on whales than research activities, would be short-term in nature, and would likely be recovered from. While it is possible that approaches or unsuccessful harpoon attempts could result in increased stress response that causes changes in behavior (e.g., moving to a new feeding area, increased swimming speed), these changes are likely to be small and temporary. Thus, they are unlikely to result in long-term impacts to individuals or abundance. It is also possible that animals could reduce their usage of or stop using an area because of the disturbance associated with a hunt. While possible, the data do not show that these activities will cause PCFG whales to leave the range, nor will the disturbance likely deter whales that may temporarily relocate to other areas from eventually retuning to resume feeding in the Makah U&A or OR-SVI region. Subsection 4.1, Introduction, describes both the maximum and the likely number of PCFG, OR-SVI, and Makah U&A whales that could be killed under each alternative from a combination of being harvested or struck and lost. That information is summarized in Table 4-14.

Table 4-14. Number of PCFG, OR-SVI, and Makah U&A whales that may be killed under each alternative (maximum and likely), assuming a low abundance threshold is not triggered.

Group of Whales		**No Action**	**Alternative 2[a]**	**Alternative 3**	**Alternative 4**	**Alternative 5[b]**	**Alternative 6**	**Alternative 7**
		Annual / 6-Yr / 10-yr	Annual / 6-Yr / 10-yr	Annual / 6-Yr / 10-yr	Annual / 6-Yr / 10-yr	Annual / 6-Yr / 10-yr	Annual / 6-Yr / 10-yr	Annual / 6-Yr / 10-yr[c]
Maximum # Killed		0	7 42 70	6 36 60	0.5[d] 3 5	1 6 10	3.5 21 35	Summer/fall 2; Winter/spring 3 15 25
PCFG Whales 27.3%	***Likely # Killed[e]***	0	1.9 11 19	1.6 9.8 16.4	0.5 3 5	0.25 1.5 2.5	0.96 5.7 9.6	Summer/fall 2; Winter/spring 0.82 8.5 14

Makah U&A Whales 23.4%			1.6 9.8 16	1.4 8.4 14.0		0.21 1.3 2.1	0.82 4.9 8.2	Summer/fall 2; Winter/spring 0.70 8.1 13.5

a. Likely estimates for Alternative 2 are based on 7 strikes per year.

b. Based on current estimates and assumes that all whales are struck and lost and subsequently die (see accounting rationale under Subsection 4.1.4 Alternative 5, Split-Season Hunt, *Maximum and Likely Number of PCFG, OR-SVI, and Makah U&A Whales Killed*).
c. Annual values based on a maximum of 2 whales struck in a summer/fall hunt and 3 whales struck in a winter/spring hunt. Six- and ten-year values are based on these alternating annual values.
d. Only male PCFG whales can be approached under this alternative. Theoretically, a maximum of seven whales could potentially be killed under this alternative, but this would require the PCFG abundance to more than triple, which is highly unlikely. The likely estimates reported here are based on the assumption that all whales are PCFG, OR-SVI, and MUA whales, and the current estimate of 1 whale killed every 2 years (see accounting rationale under 4.1.3 Alternate 4, Summer/Fall Hunt).
e. These numbers represent an estimate based on proportional presence in early season photo-identification data reviewed by Harris et al. (2022) and on an assumption of number of whales struck each year (see Tables 4-4, 4-6, 4-8, 4-10, and 4-12). Six- and ten-year estimates are rounded to the nearest whole number (except for Alternative 5 which relies on the carry-over of any unused fraction of the mortality limit to determine hunt frequency).

In addition, Subsection 3.4.3.4.3, PCFG Abundance and Trends, and Tables 3-8 through 3-10, describe gray whale use of PCFG survey areas—including the OR-SVI and Makah U&A areas—during the summer feeding period. These tables also show the numbers of new whales that visit the OR-SVI and Makah U&A survey areas each year, and how many of those returned in subsequent years. Also, as reflected in the increasing trends in sightings/discovery curves of unique whales (Figures 3-10a and 10b), new whales are consistently sighted and recruited in each of the survey regions. All of these data are considered in our analysis of each alternative.

In any given year in which a harvest occurred under Alternatives 2 through 7, the total number of gray whales present during the summer in the Makah U&A and OR-SVI survey areas would be at least temporarily reduced by the number of whales killed (either harvested or struck and lost) that would otherwise have spent all or part of the summer in these survey areas. The abundance of PCFG whales would also be at least temporarily reduced by the number of such whales killed. It is possible that a killed PCFG whale that would otherwise have spent all or part of the summer in the Makah U&A or OR-SVI areas (whether returning or not) could be replaced during the same year by a whale from outside those areas, as many whales feeding during the summer throughout the PCFG range move great distances among survey areas, likely attracted by the presence of prey (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). During the course of the summer feeding period, it is therefore possible that whales not previously seen in the Makah U&A or the OR-SVI survey areas (e.g., from west Vancouver Island or northern California) would travel through these areas and stay to feed on available prey. Whether replacement would occur in the same year would depend on the number of whales removed, the availability of prey within the local survey areas relative to its availability in outside areas, and the opportunity for whales from outside the area to discover an unexploited source of prey. As a matter of probabilities, the smaller the number of whales removed, the greater the chance a removed whale would be randomly replaced by a new whale in the same year. Thus, alternatives with lower rates of removal are likely to have less effect on total numbers of PCFG whales in the Makah U&A or OR-SVI survey areas during the year in which hunting occurs.

Over time, an ongoing hunt could reduce the numbers of whales in the Makah U&A and the OR-SVI survey areas, compared to the No-action Alternative. The extent of this reduction over time would depend on the number of PCFG whales killed and the rate at which new recruits would replace killed whales, as discussed above in Subsection 4.4.2.3, Change in Abundance and Viability of PCFG Whales. Although it is not possible to predict the potential decrease in numbers of whales, it is reasonable to expect that the fewer the number of whales removed, the less the decrease. Regardless of whether hunting occurs, gray whale numbers in the Makah U&A or OR-SVI survey areas during the summer feeding period are expected to fluctuate over time as prey availability fluctuates in these areas relative to other feeding areas.

The number of whales in the Makah U&A or OR-SVI survey areas could also be affected if gray whales changed their distribution and habitat use in response to a tribal hunt under the action alternatives. Responses could include changes in the distance from shore that whales travel during migration, changes in the amount of time spent by whales while in the Makah U&A or OR-SVI areas, or changes in the approachability of whales. Gray whales being pursued by whale-watching vessels have been observed to change course and alter swimming speed and respiratory patterns temporarily (Subsection 3.4.3.6.6, Vessel Interactions). Studies of whale-watching activities in the lagoons of Baja California documented that gray whales were less likely to flee as the season progressed (Subsection 3.4.3.6.5, Offshore Activities and Underwater Noise). It is reasonable to expect that whales approached by Makah whale-hunting vessels would react temporarily in a similar manner. It is uncertain what the long-term effects would be on whales exposed to repeated approaches. The studies of whale-watching activities suggest the whales might become habituated and have less of a reaction the more frequently they are approached. While we have limited information on how whales would react to unsuccessful harpoon attempts, the reaction may be similar to that observed in whales that are tagged or biopsied. Such reactions could range from subtle to overt (e.g., a brief flinch to fluke slapping and rapid swimming) but are most likely temporary changes in behavior (Subsection 3.4.3.5.3, Whale Response to Being Struck). Based on these observations, it is likely that any changes in gray whale behavior due to unsuccessful strike attempts or training harpoon throws would be short-term in nature and would not have lasting effects on the behavior of targeted or nearby whales such that they would begin to avoid vessels. Scores of whales have been hunted and killed by Chukotka Natives over several years (Table 3-52), yet whales continue to be available for harvest, suggesting that hunt-related activities have not resulted in major changes in gray whale numbers, distribution, or habitat use in that area.

During migration, it is uncertain what factors affect gray whale distribution and habitat use. While there is evidence that gray whales will alter course or swimming speed in response to disturbances, there is no evidence that the alteration is more than temporary (Subsection 3.4.3.6, Known and Potential Anthropogenic Impacts). Clarke and Moore (2002) found there was little evidence that gray whales disturbed by human activities travel far in response to disturbances or remain disturbed for long.

During feeding, the factor most strongly affecting gray whale distribution and habitat use is likely the availability of prey. Darling et al. (1998) and Moore et al. (2007) document abandonment of feeding areas and establishment of new feeding areas linked to natural variation in prey availability. Feeding gray whales change location and habitat to exploit the optimum prey species at any one time, based on abundance, density, size, caloric content, and predation pressure. Such factors may vary by season and year, depending on environmental variability and the population dynamics of prey (Subsection 3.4.3.1.4, Feeding Ecology and Role in the Marine Ecosystem).

Gray whales using the PCFG portion of the summer range tend to move up and down the coast during the feeding period, presumably searching for prey. Some whales remain in local survey areas for weeks or months, while others may be present only for brief periods (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). It is possible that a hunt and associated activities in the Makah U&A might disturb whales, causing them to move elsewhere in search of feeding opportunities. The severity of this effect would depend, in part, on the extent of the disturbance. Thus, alternatives that result in more whales approached or subjected to harpoon attempts, or result in more days of hunting, are likely to cause more disturbance of feeding gray whales. The severity of the effect would also depend, in part, on the sensitivity of gray whales to disturbance in feeding areas. Available information indicates that feeding gray whales may not abandon feeding areas because of hunt-related disturbance. For example, the pursuit of gray whales during the aboriginal hunt in the Chukotkan region of Russia does not appear to have diminished the opportunity for that subsistence hunt, as it has been ongoing for many decades. This indicates that, at least in one part of their summer range, gray whales have not abandoned areas where they have been subjected to many years of hunting.

Some disturbance-related information is available for gray whales in the Makah U&A and elsewhere in the PCFG region, mostly during the spring migration period. In 1999, Makah whaling crews hunted for up to 11 hours per day on 4 days between May 10 and 17, and actively pursued gray whales (including harpoon throws) at various locations on three days. In addition, aircraft and a number of protest vessels were active near the hunters, and two of these vessels were observed to come in contact with gray whales: one ran over the top of a whale and temporarily stunned it, and another vessel hit the flukes of a diving whale. In 2000, Makah crews hunted an average of 7 hours per day on 7 days between April

17 and May 29. During that time, hunters encountered an estimated 58 whales and made three harpoon throws, one of which may have grazed an animal. Aircraft and protest vessels were also active during the 2000 hunt. Despite this activity, gray whales continued to be sighted in the Makah U&A, OR-SVI, and PCFG survey areas during and after hunting had stopped in 1999 and 2000 (as well as the following year, 2001), including several PCFG whales that were sighted in the Makah U&A during consecutive years and one that was sighted there during all 3 years (J. Laake, pers. comm., NOAA Fisheries Statistician, March 11, 2014).

More recently, during the unauthorized hunt in September 2007 (i.e., during the summer feeding period), the Makah Tribe's biologist reported on the distribution and behavior of gray whales in the vicinity of the whale that had been harpooned, shot, and eventually killed in the Strait of Juan de Fuca (Subsection 3.4.3.5.2, Whale Response to Being Pursued). Anecdotal reports noted that other gray whales could be seen spouting in the area during the hunt and seemed unaffected by the hunt and Coast Guard and fishing boats in the area. Three days after the hunt the biologist sighted two gray whales within 0.6 miles (1 km) of where the killed whale had been harpooned, and noted that these whales exhibited "normal feeding behaviors and showed no escape behavior or agitation when approached by the vessel for photographs." While it is not possible to say how many whales would have been present without these hunt-related disturbances, taken together, these reports suggest that gray whales would not abandon the Makah U&A or other areas in the PCFG range as a result of limited hunt-related activity (e.g., compared to that of the Chukotkan gray whale hunt).

Concerns about whales avoiding or abandoning the Makah U&A as a result of hunt-related activity could be addressed by continued monitoring aimed at detecting changes in whale distribution and habitat use, although it would be difficult to detect trends in whale presence, and changes in distribution would more likely be related to changes in prey distribution rather than hunt-related activity. Other options to address this concern include setting limits on the numbers of whales that could be approached, subjected to strike attempts, or struck and lost.

4.4.2.5 Welfare of Individual Whales - Method of Striking and Killing; Time to Death; Hunting Efficiency

The Tribe proposes to hunt gray whales using a toggle-point harpoon to strike and secure whales and a .50 caliber rifle to kill those that have been struck and secured. The Tribe also proposes a number of measures to contribute to the safety and efficiency of the hunt, including a minimum distance from a whale before firing; minimum visibility conditions under which a weapon may be fired; motorized chase vessels to pursue whales, to provide a shooting platform, and to tow killed whales to shore; and training for hunters. In addition to the Tribe's proposed hunting weapons, this analysis considers the

option of using explosive projectiles to strike and kill gray whales, either attached to a hand-thrown harpoon or delivered by a shoulder gun. These techniques have been used in the Chukotka Native gray whale hunt. Explosive projectiles may contain black powder or penthrite. The Proposed Hunting Method portion of Subsection 2.3.2.2., Gray Whale Hunt Details, describes these hunting weapons, either of which may be used with any of the action alternatives (Alternatives 2 through 7).

This analysis examines the manner of death and the time to death of individual whales using either of two different general hunting methods: (1) a toggle-point harpoon for striking whales and a .50 or .577 caliber rifle for killing whales, or (2) an explosive projectile for both striking and killing whales, delivered either using a hand-thrown darting gun (a striking weapon that attaches a line and floats to the whale) or a shoulder gun (a killing weapon that does not secure the whale and is not used until the whale is secured by a hand-thrown harpoon or darting gun). It also examines the potential for individual whales to be struck and lost, compared to whales struck and successfully landed (referred to as hunting efficiency). The more efficient the hunt, the greater the likelihood that fewer whales would be struck and lost in reaching the hunting quota, thus limiting impacts to fewer individual whales. Also, more efficient hunts could reduce the number of encounters with whales exhibiting aggressive behavior (i.e., as in the Chukotkan hunts, Subsection 3.4.3.5.3 Whale Response to Being Struck).

For Alternatives 2, 4, 5, 6, and 7, in addition to the weapons described above, the Tribe would use a 30-foot (9.1-m) wooden canoe to transport and position the harpooner. For Alternative 3, the harpooner would most likely be transported and positioned using a motorized vessel. For the reasons described in Subsection 4.1.3.4, Potential Number of Unsuccessful Harpoon Attempts and Approaches, this analysis assumes that a hunt under Alternative 3 using all motorized vessels would be about as efficient as a hunt using a canoe to position the harpooner. This section does not focus on the welfare of individual whales (refer to Subsection 3.4.3.5, Welfare of Individual Whales) that would be the target of pursuit or unsuccessful harpoon attempts but not killed. Welfare effects on those whales are considered at the scale of the ENP gray whale stock and of whales that use local survey areas (Subsection 4.4.2.1, Change in Abundance and Viability of the ENP Gray Whale Stock, and Subsection 4.4.2.4, Change in Numbers of Gray Whales in the Makah U&A and OR-SVI areas). This section does, however, consider whether approaches by Makah hunting vessels and unsuccessful harpoon attempts would affect gray whale distribution and habitat use.

4.4.2.5.1 Method of Striking and Killing, Time to Death

A toggle-point harpoon penetrates the epidermis and blubber of the whale and toggles open to secure the whale. The area of trauma is the area penetrated by the harpoon. There is evidence that a harpoon strike causes pain, as whales may respond to being struck by diving, thrashing, or ramming a boat

(Subsection 3.4.3.5.3, Whale Response to Being Struck). Following the harpoon strike that secures the whale, the whale is shot with bullets targeted at the brain or central nervous system to cause death by penetrating and damaging the brain or central nervous system. Like the harpoon strike, a bullet causes trauma in the area of penetration. Time to death for the whale killed with a .577 caliber bullet in the Makah hunt in 1999 was 8 minutes from the time the whale was struck with the harpoon until it was rendered insensible from the second of two rifle shots. Time to death for the whale killed in the unauthorized hunt in 2007 was 11 hours from the time the whale was struck (or the first shot was fired) until the whale apparently died and sank. In the 2008 Chukotka Native hunt, the Russian Federation reported that the maximum number of shots per gray whale killed (120 animals) was 140 and the mean and maximum time to death was 31 minutes and 95 minutes, respectively. It is reasonable to expect that average time to death in a Makah hunt using a .50 or .577 caliber rifle as the killing weapon would be shorter than average time to death in the Chukotka Native hunt because the Makah Tribe would use a higher caliber rifle, which would kill a gray whale more effectively than a lower caliber rifle used by the Chukotka Native hunters (Subsection 3.4.3.5.4, Method of Killing and Time to Death). It is also possible that other requirements of the Makah hunt (minimum visibility conditions, minimum shooting distance, use of a look-out, and training) would result in a shorter time to death than documented in the Chukotka Native hunt.

The time to death of the whale during the unauthorized Makah gray whale hunt in 2007 is not a valid comparison to the expected time to death in an authorized hunt for the following reasons. During the 2007 unauthorized Makah gray whale hunt, many of the procedures proposed by the Makah were not followed (such as training of the shooter) (Subsection 3.15.2.2, Weapon Safety Regulations and Authorities). In addition, the at-sea intervention of the Coast Guard and NOAA's subsequent deliberation regarding what action to take with the wounded whale prevented the tribal members or tribal authorities from taking further action to kill the whale more expeditiously. In addition, it is not known what ammunition the unauthorized hunters used or the number of times that each rifle was fired. The Makah marine mammal biologist reported that the hunters were in possession of both a .460 and a .577 caliber rifle, and that four harpoons were embedded in the whale and 16 bullet wounds were observed. The experience of the 2007 unauthorized hunt emphasizes the importance of adopting and enforcing procedures governing the safety and humaneness of the hunt, in the event a hunt is authorized.

Concerns about time to death for individual whales, particularly in light of the unauthorized Makah hunt in September 2007, could be addressed by improved enforcement of the regulations proposed by the Makah to govern a hunt, including training of riflemen and other members of the whaling crew,

maintenance and control of weapons and ammunition, and requirements for a chase boat with a lookout. It is uncertain whether use of an explosive projectile instead of a rifle could reduce time to death. Other options for reducing time to death include improved enforcement of the moving exclusionary zone (MEZ) so protest vessels do not disrupt the hunt and hunting during better weather conditions (Alternatives 4 and 7).

The alternative method of striking and killing whales is the use of explosive projectiles, delivered either by a hand-thrown darting gun or a shoulder gun (Subsection 3.4.3.5.4, Method of Killing and Time to Death, Explosive Grenade as the Killing Weapon). Explosive projectiles cause more extensive trauma at the site of penetration than a harpoon or bullet and can cause trauma at a farther distance from the site of penetration. Unlike a toggle-point harpoon, which would not kill a whale immediately, an explosive projectile used for striking a whale may result in instantaneous or nearly instantaneous insensibility or death. In 2006, for whales killed using a darting gun with a black powder explosive projectile, Chukotka Native hunters reported an average time to death of 32 minutes for 88 whales (minimum 3 minutes, maximum 3 hours). In the 2002 season, the average time to death was also 32 minutes (maximum of 56 minutes) and hunters used an average of 2.7 darting gun projectiles per whale killed; this ratio has remained relatively stable during the past decade. In field trials with penthrite grenades in the Alaska bowhead hunt, time to death was on average 50 percent of the time to death as compared to using black powder grenades. It is uncertain what the average time to death would be for gray whales killed in a Makah gray whale hunt using explosive projectiles as the striking and killing weapon, though it is possible that average time to death would be lower than with the alternative method (toggle-point harpoon and rifle) because the striking weapon has the potential to quickly kill the whale or render it insensible.

4.4.2.5.2 Timing of Hunt and Time to Death

Regardless of the method selected, whales killed under Alternative 4 or 7 (i.e., a summer/fall hunt scenario) might experience the shortest time to death. This is because the other action alternatives could include hunting during winter and spring months when weather and sea conditions are less favorable, which might hamper the accuracy of hunters using harpoons, rifles, or explosive projectiles. Less accurate weapon strikes would likely increase the time to death (Subsection 3.4.3.5.4, Method of Killing and Time to Death). Also, under Alternative 4 and the summer/fall hunt under Alternative 7, it is likely that whales would exhibit feeding behaviors (e.g., milling in a localized area and shorter dive times) that might allow hunters to better position themselves for more accurate weapon strikes. Alternative 7 and the other action alternatives do allow for hunting in May when ocean conditions are also relatively good. However, there is also a greater chance that hunters would encounter actively

migrating whales during this time, likely making them more difficult to intercept and strike with high accuracy.

4.4.2.5.3 Hunting Efficiency

Of the more than 1,100 whales harvested by Chukotkan hunters during the period 2003 to 2011, less than 3 percent have been struck and lost (averaging 2.3 percent per year) (i.e., a hunt efficiency rate of over 97 percent). In recent years, the Chukotkan hunters report an average of 1 percent struck and lost (Table 3-12). The Russian Federation reported that Chukotka Native hunters experienced fewer whales struck and lost when explosive projectiles were used. Given the lack of experience with a Makah gray whale hunt, it is not possible to predict the proportion of whales likely to be struck and lost under any of the alternatives, nor is it possible to predict the relative proportion of struck-and-lost whales using the alternative hunting methods. The Makah proposal (Alternative 2) would allow for 18 whales struck and lost over 6 years and 24 harvested (24 out of 42 whales equals a 57 percent efficiency rate). For purposes of analyzing impacts on gray whales, NMFS assumes that the Tribe would each year reach the maximum limits on whales that could be struck (based on current conditions and estimates). For each action alternative the limits are as follows:

- **Alternative 2**: seven strikes per year, of which at most three can be struck and lost, and at most four on average can be harvested. Efficiency rate = 57 percent (assuming four whales harvested out of seven strikes).
- **Alternative 3**: six strikes per year, of which at most two can be struck and lost, and at most four on average can be harvested. Efficiency rate = 67 percent (assuming four whales harvested out of six strikes).
- **Alternative 4**: one strike every other year; whale is either struck and lost or harvested. Efficiency rate = 100 percent (assuming a struck whale is harvested).[12]
- **Alternative 5**: five strikes per year, of which at most one can be struck and lost, and at most four on average can be harvested. Efficiency rate = 80 percent (assuming four whales harvested out of five strikes).
- **Alternative 6**: four strikes per year, of which at most four can be struck and lost, and at most four on average can be harvested. Efficiency rate = 100 percent (assuming all struck whales are harvested).

[12] As noted in the text, under current conditions we assume there would be one strike every other year. While in theory, there could be up to seven strikes per year under this alternative, that is extremely unlikely given that the minimum population estimate for PCFG whales would need to more than triple while other variables (such as Rmax and the recovery factor) remained the same.

- **Alternative 7**: Winter/spring hunt year: three strikes or struck and lost (up to three harvested); efficiency rate = 100 percent (assuming three whales harvested out of three strikes). Summer/fall hunt year: two strikes or struck and lost, up to one harvested (therefore two strikes allowed only if the first whale was struck and lost). Efficiency rate = 50% (assuming one whale harvested out of two strikes).

Concerns about hunting efficiency could be addressed by decreasing the allowable numbers of whales struck and lost in a Makah hunt. Concerns could also be addressed by allowing hunting during more favorable weather conditions, which might improve the accuracy of hunters using harpoons, rifles, or explosive projectiles. More accurate weapon strikes might result in fewer whales struck and lost and thus a higher efficiency rate. In addition, better weather conditions would make it easier to land a killed whale, potentially decreasing the proportion of struck and lost whales.

4.4.3 Evaluation of Alternatives

The following sections consider the potential for each of the alternatives to affect (1) a change in abundance and viability of the ENP gray whale stock, (2) a change in abundance and viability of the WNP gray whale stock, (3) a change in abundance and viability of PCFG whales, (4) a change in numbers of gray whales using the Makah U&A and OR-SVI survey areas, or (5) the welfare of individual whales. The various alternatives incorporate mitigation measures (e.g., hunt timing and harvest limits), and we have highlighted additional mitigation considerations, as appropriate, in our analysis.

To summarize, the risk of adverse effects on the abundance of the ENP gray whale stock as a whole would likely be the same under all of the alternatives because the IWC catch limit remains the same under all alternatives. Based on past practice, it is reasonable to expect that the United States would transfer, and the Chukotka Natives would harvest, any unused Makah share of the catch limit. The result would likely be that the same total number of whales would likely be removed from the stock by hunting. The difference between the No-action Alternative and the action alternatives is that under the action alternatives, some of that harvest would take place by Makah hunters in the coastal portion of the Makah U&A. Thus, none of the action alternatives would likely affect the abundance of the ENP gray whale stock as a whole, compared to the No-action Alternative. Expected effects of the alternatives in the event the United States did not transfer any unused portion of the catch limit to Russia are discussed in detail below.

The risk of adverse effects on the WNP gray whale stock would be lowest under the No-action Alternative (no hunting) and Alternative 4, which is designed to avoid WNP gray whales by limiting

hunting to the summer and fall months when WNP gray whales would be feeding off Sakhalin Island. The likely effects of the other action alternatives on the WNP gray whale stock, in the event that a WNP gray whale is inadvertently struck, are described below.

With respect to impacts on the PCFG, Subsection 3.4.3.4, Pacific Coast Feeding Group (PCFG) of Gray Whales, summarizes the best available information pertaining to PCFG whales and the basis for NMFS' conclusion that the PCFG seems to be a distinct feeding aggregation and may warrant consideration as a separate stock in the future (Carretta et al. 2023). If PCFG whales are uniquely adapted to exploit feeding areas in the southern portion of the ENP summer range, and any of the action alternatives compromised the viability of the PCFG, there could be an effect on the long-term viability of the ENP stock as a whole (Subsection 4.4.2.1, Change in Abundance and Viability of the ENP Gray Whale Stock). However, given that the entire herd migrates through the PCFG range twice each year, and given the evidence that individual whales vary their use of feeding areas inside and outside of this range, both across years and within years, it is likely that whales would continue to discover and use the PCFG feeding areas, even if an action alternative temporarily reduced the abundance of PCFG whales. The lowest risk to PCFG gray whales that have been seen in the Makah U&A and OR-SVI survey areas would occur under the No-action Alternative, because it is unlikely that PCFG whales would be present in the area of the Chukotka hunt and thus killed under the No-action Alternative. The risks to whales in the PCFG range would be higher under the action alternatives because of the likelihood that some PCFG whales (including Makah U&A whales and OR-SVI whales) would likely be killed in a Makah hunt. For each action alternative, the maximum and likely numbers of PCFG whales that might be killed in a year (based on current estimates) are as follows (from Table 4-1):

- **Alternative 2**: 5 PCFG whales maximum, 1.9 whales likely
- **Alternative 3**: 4 PCFG whales maximum, 1.6 whales likely
- **Alternative 4**: 1 PCFG whale every other year maximum and likely
- **Alternative 5**: 1 PCFG whale maximum, 0.25 (1 whale every 4 years) likely
- **Alternative 6**: 3.5 PCFG whales maximum, 0.96 whales likely
- **Alternative 7**: winter/spring hunts: 3 PCFG whales maximum, 0.82 whales likely. Summer/fall hunts: 2 PCFG whales maximum, 2 whales likely (assuming the first is struck and lost)

4.4.3.1 Alternative 1, No Action

Under the No-action Alternative, we would not allocate a gray whale quota to the Makah Tribe and no authorized hunting by the Tribe would occur. As described in Subsection 4.1.1.3, Potential Number of

ENP and PCFG Whales Killed, the current annual and 7-year IWC catch limits set for ENP gray whales are based on a joint request of the Russian Federation (for Chukotka Natives) and the United States (for the Makah Tribe). Because the United States would likely transfer any unused share of the catch limit to Russia, the number of gray whales that may be landed from the ENP stock during the 7-year period from 2019 through 2025 would likely be the same under the No-action alternative as under current conditions (980 whales over 7 years, with no more than 140 whales taken in any one year). Thus, the effects on the abundance and viability of the ENP gray whale stock would likely not differ from the current conditions described in Subsection 3.4.3.3, Eastern North Pacific (ENP) Gray Whales.

Similarly, under the No-action Alternative, any stress-related impacts of ENP gray whales would be similar to current conditions, in which the Chukotkans could harvest the entire IWC catch limit. If the United States did not transfer its unused share of the catch limit for the 2 years remaining in the catch limit (2024 to 2025), there would be 14 fewer whales struck under the No-action alternative than under current conditions. That difference in stress-related impacts that would result from the reduced number of strikes is unlikely to have any effect on the abundance and viability of the ENP gray whale stock because 10 whales are a tiny fraction (less than 0.1 percent) of the 14,526 animals in this stock.

Under the No-action Alternative, the health, abundance, and habitat conditions for WNP and ENP stocks of gray whales (including PCFG whales and summer feeding whales in the Makah U&A and OR-SVI survey areas) would remain as under current conditions. Domestic prohibitions on gray whale take pursuant to section 101 of the MMPA would continue. Factors that could cause a change in distribution or habitat use, such as variability in prey abundance from environmental perturbation, vessel traffic and noise, or commercial fisheries, would similarly be expected to remain at present levels.

4.4.3.2 Alternative 2, Tribe's Proposed Action

Under Alternative 2, whale hunting may occur from December 1 through May 31 in the coastal portion of the Makah U&A. Annually, an average of four whales could be harvested by the Makah Tribe, a maximum of seven could be struck, and a maximum of three could be struck and lost. During any 6-year period, up to 24 whales might be harvested, with 42 struck and 18 struck and lost. As many as 353 whales may be approached by whale hunting vessels in any one year and up to 42 whales may be exposed to unsuccessful harpoon attempts. With up to four whales likely being harvested each year, there could be up to 64 rifle shots fired or 12 grenade explosions per year. While it is possible that the Tribe could hunt on 43 days between December and May, inclement weather conditions might practically limit hunting to a total of 33 days during March through May. Given the limited number of

likely hunting days available under Alternative 2, the Tribe might not be able to harvest the full number of whales allowed.

4.4.3.2.1 Change in Abundance and Viability of the ENP Gray Whale Stock

The potential direct and indirect mortality resulting from a whale hunt and hunt-related activities under Alternative 2 would be unlikely to change ENP gray whale stock abundance or viability compared to the No-action Alternative. As noted in Subsection 4.1.1.3, Potential Number of ENP and PCFG Whales Killed, the catch limit for the ENP gray whale stock set by the IWC would not change under this or any of the other alternatives; thus, the same number of ENP gray whales would likely be harvested over 6 years under Alternative 2 as under the No-action Alternative. If, over 6 years, the Makah Tribe hunts for 24 whales resulted in a higher level of stress-related impacts than would occur if those 24 whales were harvested in a Chukotkan hunt under the No-action Alternative, the difference is unlikely to have an appreciable effect on the abundance and viability of the ENP gray whale stock as a whole. This is because the stress-related impacts associated with harvesting 24 whales over 6 years is likely to be minor in the context of the existing Chukotkan harvest level of 840 whales over 6 years.

If under the No-action Alternative the United States did not transfer unused portions of the catch limit to Russia, Alternative 2 would represent an increase in mortality of at most 14 gray whales over the 2 remaining years of the catch limit (2024 through 2025) (seven struck whales per year times 2 years), compared to the No-action Alternative. Because 14 whales are a tiny fraction of the overall ENP gray whale stock (less than 0.1 percent), the increase in mortalities under Alternative 2 would be extremely unlikely to affect gray whale viability, compared to the No-action Alternative.

If PCFG whales are uniquely adapted to exploit feeding areas in the southern portion of the ENP summer range, and that adaptation were lost if the PCFG were compromised, Alternative 2 has the potential to affect the long-term viability of the ENP stock as a whole. However, as described in Subsection 4.4.3.2.3, Change in Abundance and Viability of PCFG Whales, the best available information indicates that the PCFG would still be viable with a hunt under Alternative 2, so there is no reason to believe that this alternative would affect the ENP stock as a whole.

4.4.3.2.2 Change in Abundance and Viability of the WNP Gray Whale Stock

Available sighting data suggest that WNP whales could be encountered in the vicinity of the Makah U&A (Subsection 3.4.3.2.2, WNP Seasonal Distribution, Migration, and Movements) during much of the hunting season under Alternative 2, perhaps with the exception of early May to late December. Modeling based on Moore et al. (2023) estimates that between 2.8 and 4.2 WNP gray whales may be approached per year under Alternative 2. This assumes that all 353 training and hunting approaches are utilized annually, that each approach is made on a unique individual, and that all approaches are made

during the winter and spring months when WNP gray whales may be present in the hunt area. It is unlikely that all of these assumptions will be met; therefore, this is a precautionary estimate of the potential impacts to WNP gray whales under Alternative 2. Assuming that all harpoon attempts are made each year, between 0.056 and 0.084 WNP gray whales may be subjected to unsuccessful harpoon attempts annually (Table 4-4). These estimates represent an increased risk to these whales compared to the No-action Alternative.

While there is limited data on how whales would react to unsuccessful harpoon attempts the reaction may be similar to that observed in whales that are tagged or biopsied (i.e., ranging from a subtle to overt response resulting in a potential temporary change in behavior). Based on these observations, it is likely that any changes in gray whale behavior due to unsuccessful strike attempts or training harpoon throws would be short-term in nature and would not have lasting effects on the behavior of targeted or nearby whales such that they would begin to avoid vessels.

While the chances of killing a WNP whale are low, even over a 6-year period, the loss of WNP whales, particularly reproductive females, from this small stock could be a conservation concern depending on the number lost and the time period over which such losses occurred. To mitigate for the possibility of a Makah hunt killing a WNP whale, regulations governing a hunt could require a suspension of the hunt if a WNP whale were killed. Procedures for photographing any whale that is landed would make it likely a WNP whale would be identified if it were landed. If a WNP whale were struck and lost, it is possible, though not certain, it could be identified.

4.4.3.2.3 Change in Abundance and Viability of PCFG Whales

Compared to the No-action Alternative, Alternative 2 could reduce the abundance of PCFG gray whales, which could potentially affect the viability of the PCFG. As described in Subsection 4.1.2, Alternative 2 and Table 4-1, the current maximum number of PCFG whales that could be killed under Alternative 2 would be 5 per year. However, it is more likely that an average of 1.9 PCFG whales per year might actually be killed (and 11.5 whales over 6 years) given the high proportion of non-PCFG whales present in the Makah U&A during the spring portion of the hunting season when the Tribe is most likely to hunt.

If 1.9 PCFG whales were killed, it would represent a 0.9 percent reduction in the current abundance estimate of 212 PCFG whales (Harris et al. 2022). Compared to the No-action Alternative, this would represent a small decrease in abundance during the year in which PCFG whales were removed. Over time, it is uncertain whether or to what extent the death of 1.9 PCFG whales per year might decrease the abundance of the PCFG. During the years 2008 to 2017, there were 12.3 new recruits on average, 7.9 (64 percent) of which were not identified as calves (Calambokidis et al. 2019). At the current rate

of recruitment, the PCFG abundance trend appears to be stable. It is possible external recruits into the PCFG could increase, compared to the No-action Alternative, as a result of the removal of 1.9 PCFG whales, in which case the abundance of the PCFG could remain at its current level.

In contrast to the No-action Alternative, Alternative 2 could reduce the numbers of PCFG whales and potentially affect the PCFG's viability. An analysis by the IWC Scientific Committee suggests the PCFG would nevertheless remain viable with a hunt under Alternative 2. As described in Subsection 4.4.2.3, Change in Abundance and Viability of PCFG Whales, the IWC's Scientific Committee evaluated the Makah hunt proposal (Alternative 2) via models that use a 100-year time horizon. That committee's conclusion indicates that the PCFG would be viable as long as the hunt included a bycatch formula to limit the strikes on PCFG whales and annual monitoring was conducted to assess the availability of PCFG whales in the Makah hunt. The committee's modeling used a bycatch formula that, under population parameters at the time, yielded a bycatch limit of 3.0 PCFG whales per year. That value is slightly greater than the number of PCFG whales likely to be killed under Alternative 2 (i.e., 1.9 whales per year), which uses the same bycatch formula as the IWC analysis, indicating that the PCFG would still be viable with a hunt under Alternative 2. If the requisite monitoring indicated a higher availability of PCFG whales then the IWC would likely reassess its conclusions via a new implementation review (Subsection 3.4.3.4.4, PCFG Status, Carrying Capacity, and Related Estimates, IWC Implementation Review of PCFG Gray Whales).

During the proposed hunting season (December through May) under Alternative 2, 27.3 percent (96 whales) of the 353 whales approached during hunt activities would be expected to be PCFG whales (Subsection 4.1.2, Alternative 2) (Table 4-4). Similarly, 11 of the 42 whales potentially subjected to harpoon attempts would be expected to be PCFG whales. While some researchers have suggested that gray whales may have altered their migration distance from shore in response to vessels and other human activity, other researchers concluded there is no evidence suggesting such a relationship (see Subsection 3.4.3.6.6, Vessel Interactions). There is no data on whether this level of disturbance would cause PCFG whales to change their distribution (i.e., avoid the hunt area). However, there are several lines of evidence that indicate the disturbance would be temporary, minor in nature, and would not prevent whales that may temporarily relocate to other areas from returning. Some aspects of approaches by Makah whale-hunting canoes would cause a disturbance similar to that observed from approaches of motorized whale-watching vessels or vessels used for photo identification work. It is known that when approached by vessels some gray whales exhibit temporary behavioral responses, such as changing course, swimming speed, and respiratory patterns (Subsection 3.4.3.6.6, Vessel Interactions). However, there is no evidence that gray whales have altered their distribution or habitat

use in lagoons in their winter range in response to the presence of whale-watching vessels. Thus, whale response to approaches is likely to be temporary (minutes or hours).

It is less certain whether the intensity of unsuccessful harpoon attempts would result in more than a temporary disturbance of PCFG whales and cause them to avoid portions of their range either for a short period (days to weeks) or a longer period (for example, over a period of years). As described in Subsection 3.4.3.3.2, ENP Seasonal Distribution, Migration, and Movements, the availability of prey may be the factor most strongly affecting gray whale numbers in particular feeding areas. If prey is available throughout the PCFG range, hunting by the Makah Tribe might not result in either a short- or long-term response from summer-feeding whales. Many new whales are seen in the PCFG range every year, and there is significant interchange among survey areas within this range (Subsection 3.4.3.4.3, PCFG Abundance and Trends). Thus, even if some whales do abandon an area as a result of hunting disturbance, new whales that had not previously been exposed to hunting might come into the area. The example of gray whales hunted by Chukotka Natives may be instructive in trying to predict whether there would be a change in gray whale use of areas within the PCFG range. Scores of whales have been hunted and killed by Chukotka Natives over several years (Table 3-52), yet whales continue to be available for harvest, suggesting that hunt-related activities have not resulted in major changes in gray whale numbers, distribution, or habitat use in that area.

If hunting in the coastal portion of the Makah U&A did cause a change in distribution, it is likely that whales would shift to using adjacent areas, especially the Strait of Juan de Fuca portion of the Makah U&A and southern Vancouver Island, because those areas already have high rates of interchange with the proposed hunt area. Also, because hunting activities under Alternative 2 would end prior to the June through November feeding period, it is possible that PCFG whales might only temporarily avoid the coastal portion of the Makah U&A given that there would be 6 consecutive months with no hunt-related activities. Thus, available information indicates that gray whale distribution and habitat use under Alternative 2 would not change appreciably compared to the No-action Alternative.

4.4.3.2.4 Change in Numbers of Gray Whales Using the Makah U&A and OR-SVI Survey Areas

Alternative 2 would result in gray whales being hunted in the coastal portion of the Makah U&A, which is a subset of the OR-SVI survey region and situated within the migration corridor of the entire ENP herd of gray whales. Such hunting could reduce the numbers of gray whales in these areas during the summer feeding period, as compared to the No-Action alternative, either as a result of whales being killed or as a result of feeding whales changing their distribution during the summer feeding period.

Change in Numbers as a Result of Whales Being Killed

As described in Subsection 4.1.2, Alternative 2 and Table 4-4, based on current data, the maximum number of whales previously seen in the OR-SVI or Makah U&A survey areas that may be killed would be five per year. However, it is more likely that an average of 1.8 OR-SVI whales or 1.6 Makah U&A whales might actually be killed each year (and 11 or 9.8 whales, respectively, over 6 years) given the available data regarding the presumed proportional presence of these whales in the proposed hunt area during the March through May time period, when the Tribe is most likely to hunt.

It is uncertain whether OR-SVI whales or Makah U&A whales killed under Alternative 2 would be replaced in the same year in which they were killed or in subsequent years because of the uncertainty regarding the recruitment mechanism and rate of recruitment into the PCFG and the uncertainty regarding the distribution of both PCFG and non-PCFG whales in these survey areas during the summer months. As described above in Subsection 4.4.2.4, Change in Numbers of Gray Whales in the Makah U&A and OR-SVI Areas, whales in these survey areas during the summer months include both whales that have visited the PCFG area in more than 2 years [PCFG whales] and whales that visit only once and are never sighted again [transient, non-PCFG whales]. Harris et al. (2022) analyzed the most recent sighting data for PCFG whales. From 1996 through 2020, there were 645 uniquely identified whales sighted in the OR-SVI area between June and November. An average of 112 whales are sighted each year, and of these an average of 24 whales are newly seen each year (ranging from 8 to 56 whales, and 11 whales for 2020). The annual average number of whales newly seen and then seen again in a subsequent year ("returning" whales) for 1996 to 2019 is 13 whales (ranging from 3 to 37 whales, and 10 whales for 2019, the most recent year reported). In the Makah U&A, 356 uniquely identified whales have been sighted from 1996 through 2020 in the June through November time period. An average of 33 whales are sighted each year, and of these an average of 14 whales are newly seen each year (ranging from 1 to 29 whales, and 18 whales for 2020). The annual average number of whales newly seen and then seen again in a subsequent year for 1996 to 2019 is 7 whales (ranging from 2 to 18 whales, and 11 whales for 2019, the most recent year reported). These sighting data, while subject to the survey limitations described in Subsection 4.4.2.3, Change in Abundance and Viability of PCFG Whales, demonstrate that many new whales are seen each year in these OR-SVI and Makah U&A areas. Of these whales, variable but large numbers are seen (or never seen) again.

Based on the annual average number of newly seen whales in the Makah U&A and OR-SVI survey areas (14 and 24 whales, respectively), it is possible that if an average of one to two Makah U&A or OR-SVI whales were removed under Alternative 2, they would be replaced during that year with new Makah U&A or OR-SVI whales. In that case, Alternative 2 would not result in a decrease in the total

number of gray whales using the Makah U&A and OR-SVI survey areas during a given summer feeding period, compared to the No-action Alternative.

Over time, an ongoing hunt could reduce the abundance of PCFG whales and, thereby, reduce the number of PCFG whales using the Makah U&A and OR-SVI areas. The extent to which a hunt would reduce abundance over time would depend on the rate at which external recruits would replace killed whales, similar to the discussion above for change in numbers of PCFG whales (Subsection 4.4.3.2.3, Change in Abundance and Viability of PCFG Whales). It seems likely that if the killed Makah U&A or OR-SVI whales were returning whales, they would be replaced in subsequent years with another returning whale, based on the average number of newly seen whales in the Makah U&A and OR-SVI survey areas that are then seen again in a subsequent year (7 and 13 whales, respectively). If for some reason new whales (that become returning whales) did not take the place of killed returning whales in subsequent years, the Tribe's allowable bycatch level would decrease over time because of the Tribe's proposal to establish limits on PCFG whales based on the annually updated estimate of returning OR-SVI whales. It is also possible that the removal of PCFG whales would result in the presence of more non-PCFG whales using the Makah U&A and OR-SVI during the summer months (i.e., whales that appear in the area in only one year and do not return again). This is uncertain, however, so the analysis does not assume it would occur.

Change in Numbers as a Result of Change in Distribution of Feeding Whales

During the proposed hunting season (December through May) under Alternative 2, annually about 83 whales approached during hunt activities would be expected to be Makah U&A whales, while 93 would be expected to be OR-SVI whales (Subsection 4.1.2, Alternative 2) (Table 4-4). Thus, of the 353 whales potentially approached, approximately 23 percent (on average) would be Makah U&A whales and 26 percent would be OR-SVI whales. Of the 42 whales potentially subjected to harpoon attempts, 9.8 would be expected to be Makah U&A whales and 11 would be expected to be OR-SVI whales. It is unknown whether this level of disturbance would cause whales to change their distribution (i.e., avoid the hunt area), although evidence suggests that any changes would be temporary and minor (see Subsection 3.4.3.6.6, Vessel Interactions).

Some aspects of approaches by Makah whale-hunting canoes would cause a disturbance similar to that observed from approaches of motorized whale-watching vessels or vessels used for photo identification work. It is known that when approached by vessels some gray whales exhibit temporary behavioral responses, such as changing course, swimming speed, and respiratory patterns (Subsection 3.4.3.6.6, Vessel Interactions). However, there is no evidence that gray whales have altered their distribution or habitat use in lagoons in their winter range in response to the presence of whale-watching vessels.

While some researchers have suggested that gray whales may have altered their migration distance from shore in response to vessels and other human activity, other researchers concluded there is no evidence suggesting such a relationship. Thus, whale response to approaches is likely to be temporary (minutes or hours).

It is less certain whether the intensity of unsuccessful harpoon attempts would result in more than a temporary disturbance of Makah U&A or OR-SVI whales and cause them to avoid portions of the Makah U&A or OR-SVI either for a short period (days to weeks) or a longer period (for example, over a period of years). As described in Subsection 3.4.3.3.2, ENP Seasonal Distribution, Migration, and Movements, the availability of prey may be the factor most strongly affecting gray whale numbers in particular feeding areas. If prey is available in the Makah U&A or OR-SVI, hunting by the Makah Tribe might not result in either a short- or long-term response from summer-feeding whales. Many new whales are seen in the Makah U&A and OR-SVI every year, and there is significant interchange with whales from other adjacent areas in the PCFG range (Subsection 3.4.3.4.3, PCFG Abundance and Trends). Thus, even if some whales do abandon the area as a result of hunting disturbance, new whales that had not previously been exposed to hunting might come into the area. The example of gray whales hunted by Chukotka Natives may be instructive in trying to predict whether there would be a change in gray whale use of the Makah U&A and OR-SVI survey areas. Scores of whales have been hunted and killed by Chukotka Natives over several years (Table 3-52), yet whales continue to be available for harvest, suggesting that hunt-related activities have not resulted in major changes in gray whale numbers, distribution, or habitat use in that area.

Spatially, the OR-SVI area is a relatively small part (approximately 11 percent) of the entire PCFG range, but the area attracts a disproportionately high percentage (approximately 71 percent; Calambokidis et al. 2019) of PCFG whales sighted in a given year. Also, PCFG whales exhibit extensive movements during a given year and from year to year, presumably searching for prey (Subsection 3.4.3.1.4, Feeding Ecology and Role in the Marine Ecosystem, and Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). For example, Calambokidis et al. (2014) estimated that over 60 percent of PCFG whales that had been sighted on 6 or more days were seen somewhere in the OR-SVI area and across a latitudinal range of greater than 30 nautical miles (i.e., roughly equivalent to the coastal portion of the Makah U&A) (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). Therefore, it is reasonable to expect that other PCFG whales could move in and take the place of whales that leave the Makah U&A or OR-SVI areas in response to hunting. For example, PCFG whales feeding outside the OR-SVI survey areas (e.g., whales from west Vancouver Island) could take the place of whales removed from the OR-SVI, and PCFG whales

feeding outside the Makah U&A (e.g., from southern Vancouver Island) could take the place of whales removed from the Makah U&A. In addition, if there are other feeding areas that are not subject to hunting disturbance, the whales can and may easily move to those other areas. Over time and with ongoing hunt-related disturbance, fewer whales might use the hunt area (which is just one portion of the Makah U&A and OR-SVI areas), but such abandonment might be offset to some extent by new whales that recruit to the PCFG and have not been exposed to such disturbance.

Change in Numbers - Summary

Compared to the No-action Alternative, there is a risk under Alternative 2 that the killing or disturbance of whales caused by a Makah hunt could result in decreased numbers of whales using these survey areas during the summer period (especially if external recruits do not replace killed whales). However, it is likely that gray whales would continue using these survey areas during the summer months because: (1) the IWC analysis shows that PCFG whales would remain viable with a Makah hunt as conducted under Alternative 2, (2) PCFG whales are dense and abundant in the OR-SVI area, (3) PCFG whales are highly mobile within the PCFG range, (4) there are many new and returning whales available to replace killed whales, (5) the bycatch limit for PCFG whales accounts for changes in OR-SVI whale numbers, and (6) gray whales continue to return in large numbers to feeding areas where scores are actively hunted and killed each year (i.e., waters around Chukotka), suggesting that hunting will not cause them to abandon the PCFG feeding area.

4.4.3.2.5 Welfare of Individual Whales

As discussed in Subsection 4.1, Introduction, the number of gray whales that might be harvested from the ENP stock under all alternatives, including Alternative 2 and the No-action Alternative, would not change. It would remain at the existing IWC catch limit of 980 whales in a 7-year period, and no more than 140 whales in any one year. The difference is that under the No-action Alternative, the entire catch could be taken by Chukotka Natives, while under Alternative 2 the Makah Tribe could take up to 24 whales from the 980 whale catch limit.

A major difference between Alternative 2 and the No-action Alternative is in the number of gray whales that might be disturbed via vessel approaches and unsuccessful harpoon attempts. Assuming that Makah hunters could embark on hunting trips during 42.5 days per year, it is possible that 353 gray whales might be approached by Makah hunters per year and 42 of those whales subjected to unsuccessful harpoon attempts (Subsection 4.1.2, Alternative 2) (Table 4-4). The number of whales approached does not include the number that might be approached by vessels other than those used by Makah hunters. Some individual whales who encounter Makah hunters could be subsequently encountered during a hunt by Chukotkan Natives (which would typically occur during the summer and

fall months). Thus, there is a greater potential for increased disturbance under Alternative 2 compared to the No-action Alternative. However, this increased risk is extremely low; the high ENP abundance reduces the likelihood that an individual whale will encounter both Makah and Chukotkan hunters. In addition, an unsuccessful harpoon attempt—the most severe form of disturbance aside from struck and lost whales—would still be limited to 42 whales, which is a very small fraction (0.3 percent) of the ENP stock.

The proportion of whales struck and lost could be greater in a Makah hunt under Alternative 2 than a Chukotka Native hunt under the No-action Alternative because the Chukotka Natives have more recent hunting experience. In recent years, the Chukotka Natives report that one percent of the whales struck in their hunt are lost. It is not possible to predict the proportion of whales that would be struck and lost in a Makah hunt under Alternative 2, but the Tribe's proposal includes a potential of three whales struck and lost for four whales harvested before the seven-strike limit would be reached. The proportion of whales struck and lost under Alternative 2 could also be greater than the proportion in a Chukotka Native hunt because seasonal restrictions on the Makah hunt under Alternative 2 could result in hunts occurring in rough weather and sea conditions. Hunting under unfavorable conditions could reduce the accuracy of the hunters and make it more difficult to successfully land a killed whale (thus increasing the proportion of whales struck and lost).

Whales killed with a rifle in a Makah hunt under Alternative 2 could experience a shorter time to death than whales killed with a rifle in a Chukotka Native hunt because of the requirements proposed by the Makah (such as minimum visibility) and because the Makah would use a higher caliber killing weapon than the Chukotka Natives use. Whales killed with an explosive grenade(s) in either hunt would likely experience a similar time to death. Thus, compared to the No-action Alternative where the U.S. take limit is likely to be transferred to Russia, Alternative 2 could result in the same or shorter time to death, depending on the weapon used.

4.4.3.3 Alternative 3, Offshore Hunt

Alternative 3 would have the same conditions as Alternative 2 regarding the hunting season (December through May), limits on the numbers of ENP whales harvested, hunting methods, and regulatory framework. Alternative 3 would also have the same hunt area as Alternative 2, except that it would prohibit Makah hunters from making an initial strike on a gray whale within 5 miles (8 km) of shore (Makah hunters and chase boats may nevertheless have to follow any struck whale trailing harpoon lines to dispatch it, regardless of distance to shore). Alternative 3 also assumes that the Tribe would most likely conduct a motorized hunt and not use canoes, which could result in a higher likely number of hunting days (43 compared to 33) per year. Alternative 3 would differ from Alternative 2 in that a harvested whale would

only count against the PCFG limit if it met the definition of a PCFG whale (i.e., it was sighted in at least 2 years in the PCFG seasonal range). Alternative 3 would also differ from Alternative 2 in that it would include a limit on the total mortality (including struck and lost whales) of PCFG whales (3.5 whales/year, using current estimates) and a related limit for female PCFG whales based on their proportional presence (1.8 females, using current estimates) (refer to Table 4-5). The result is that while an annual average of four whales might be harvested under either Alternative 2 or Alternative 3, the limits on PCFG whales differ. Alternative 3 would limit strikes to six whales per year and struck and lost whales to two per year. During any 6-year period, up to 24 whales might be harvested, with 36 struck and 12 struck and lost. As many as 353 whales may be approached by whale hunting vessels in any one year and up to 36 whales may be exposed to unsuccessful harpoon attempts. With up to four whales likely being harvested each year, there could be up to 64 rifle shots fired or 12 grenade explosions per year. Given the limited number of likely hunting days available under Alternative 3, the Tribe might not be able to harvest the full number of whales allowed.

4.4.3.3.1 Change in Abundance and Viability of the ENP Gray Whale Stock

Like Alternative 2, the potential direct and indirect mortality resulting from a whale hunt and hunt-related activities under Alternative 3 would be unlikely to change ENP gray whale stock abundance or viability compared to the No-action Alternative. As noted in Subsection 4.1, Introduction, the catch limit for the ENP gray whale stock set by the IWC would not change under this or any of the other alternatives; thus, the same number of ENP gray whales would likely be harvested over 6 years under Alternative 3 as under the No-action Alternative. If a Makah hunt for 24 whales over 6 years resulted in a higher level of stress-related impacts than would occur if those 24 whales were harvested in a Chukotkan Native hunt under the No-action Alternative, the difference is unlikely to have an appreciable effect on the abundance and viability of the ENP gray whale stock as a whole. This is because the stress-related impacts associated with harvesting 24 whales over 6 years is likely to be minor in the context of the existing Chukotkan harvest level of 840 whales over 6 years.

If under the No-action Alternative the United States did not transfer unused portions of the catch limit to Russia, Alternative 3 would represent an increase in mortality of at most 12 gray whales over the 2 remaining years of the catch limit (2024 to 2025) (six struck whales per year times 2 years), compared to the No-action Alternative. Because 12 whales are a tiny fraction of the overall ENP gray whale stock (less than 0.1 percent), the increase in mortalities under Alternative 3 would be extremely unlikely to affect the stock's viability compared to the No-action Alternative.

If PCFG whales are uniquely adapted to exploit feeding areas in the southern portion of the ENP summer range, and that adaptation were lost if the PCFG were compromised, Alternative 3 has the

potential to affect the long-term viability of the ENP stock as a whole. However, as described in Subsection 4.4.3.3.2, Change in Abundance and Viability of PCFG Whales, the best available information indicates that the PCFG would still be viable with a hunt under Alternative 3, so there is no reason to believe that this alternative would have deleterious impacts on the ENP stock as a whole.

4.4.3.3.2 Change in Abundance and Viability of the WNP Gray Whale Stock

Available sighting data suggest that WNP whales could be encountered in the vicinity of the Makah U&A (Subsection 3.4.3.2.1, WNP Seasonal Distribution, Migration, and Movements) during much of the hunting season under Alternative 3, perhaps with the exception of early May to late December. There are some data indicating that hunters would be more likely to encounter WNP whales if hunting is restricted to offshore areas at least 5 miles (8 km) from the coast. Tracking data for two whales indicate that they could be encountered in such areas (Subsection 3.4.3.2.1, WNP Seasonal Distribution, Migration, and Movements). Modeling based on Moore et al. (2023) estimates the same risk of approach under Alternative 3 as Alternative 2. Assuming that all harpoon attempts are made each year, between 0.29 and 0.43 WNP gray whales may be subjected to unsuccessful harpoon attempts annually (Table 4-6). These estimates represent a similar level of risk to WNP gray whales as under Alternative 2, and an increased risk to these whales compared to the No-action Alternative.

There is limited data on how whales would react to unsuccessful harpoon attempts, but the reaction may be similar to that observed in whales that are tagged or biopsied (i.e., ranging from a subtle to overt response resulting in a potential temporary change in behavior). Based on these observations, it is likely that any changes in gray whale behavior due to unsuccessful strike attempts or training harpoon throws would be short-term in nature and would not have lasting effects on the behavior of targeted or nearby whales such that they would begin to avoid vessels.

While the chances of killing a WNP whale are low, even over a 6-year period, the loss of WNP whales, particularly reproductive females, from this small stock could be a conservation concern depending on the number lost and the time period over which such losses occurred. To mitigate for the possibility of a Makah hunt killing a WNP whale, regulations governing a hunt could require a suspension of the hunt if a WNP whale were killed. Procedures for photographing any whale that is landed would make it likely a WNP whale would be identified if it were landed. If a WNP whale were struck and lost, it is possible though not certain it could be identified.

4.4.3.3.3 Change in Abundance and Viability of PCFG Gray whales

Compared to the No-action Alternative, Alternative 3 could reduce the abundance of PCFG gray whales, which could potentially affect the viability of the PCFG. As described in Subsection 4.1.3, Alternative 3 and Table 4-1, the current maximum number of PCFG whales that could be killed under

Alternative 3 would be four per year. However, it is more likely that an average of 1.6 PCFG whale per year might actually be killed (and 9.8 whales over 6 years) given the high proportion of non-PCFG whales present in the Makah U&A during the spring portion of the hunting season when the Tribe is most likely to hunt. The annual average number is similar to that expected under Alternative 2.

If one PCFG whale were killed in a year, it would represent a 0.5 percent reduction in the current abundance estimate of 212 PCFG whales (Harris et al. 2022). This would represent a small decrease in abundance, compared to the No-action Alternative and under Alternative 2 (about half that expected under Alternative 2), during the year in which PCFG whales were removed. Over time, it is uncertain whether or to what extent the death of one PCFG whale per year might decrease the abundance of the PCFG whales. During the years 2008 to 2017, there were 12.3 new recruits on average, 7.9 (64 percent) of which were not identified as calves (Calambokidis et al. 2019). At the current rate of recruitment, the PCFG abundance trend appears to be stable. It is possible that external recruits could increase, compared to the No-action Alternative, as a result of the removal of one PCFG whale; in which case, the abundance of the PCFG could remain at its current level.

In contrast to the No-action Alternative, Alternative 3 could reduce the numbers of PCFG whales and potentially affect the PCFG's viability. As described above, the reduction under Alternative 3 would be roughly half that expected under Alternative 2. The IWC Scientific Committee's analysis suggests the PCFG would remain viable with a hunt under Alternative 3. As described in Subsection 4.4.2.3, Change in Abundance and Viability of PCFG Whales, the IWC's Scientific Committee evaluated the Makah hunt proposal (Alternative 2) using models with a 100-year time horizon. The committee's conclusion indicates that the PCFG would be viable using the Tribe's bycatch formula to limit the strikes on PCFG whales and with annual monitoring to assess the availability of PCFG whales in the Makah hunt. The committee's modeling used a bycatch formula that, under population parameters at the time, yielded a bycatch limit of 3.0 PCFG whales per year. That value is much greater than the number of PCFG whales likely to be killed under Alternative 3 (i.e., one whale per year), which includes PCFG mortality limits that are more restrictive than the bycatch formula in Alternative 2 and the IWC analysis, indicating that the PCFG would still be viable with a hunt under Alternative 3. If the requisite monitoring indicated a higher availability of PCFG whales, then the IWC would likely reassess its conclusions via a new implementation review (Subsection 3.4.3.4.4, PCFG Status, Carrying Capacity, and Related Estimates; IWC Implementation Review of PCFG Gray Whales).

During the proposed hunting season (December through May) under Alternative 3, 27.3 percent (96 whales) of the 353 whales approached during hunt activities would be expected to be PCFG whales (Subsection 4.1.2, Alternative 2) (Table 4-4). Similarly, 10 of the 36 whales potentially subjected to

harpoon attempts would be expected to be PCFG whales. For the reasons described under Alternative 2 (Subsection 4.4.3.2.3, Change in Abundance and Viability of PCFG Gray Whales), it is unclear how whale distribution would be affected by hunt-related approaches and unsuccessful harpoon attempts. Whale response to approaches is likely to be temporary (minutes or hours), and Chukotkan hunters have approached, struck, and killed scores of gray whales over several years with no major changes apparent in whale numbers, distribution, or habitat use in that area. The availability of prey may be the factor most strongly affecting gray whale numbers in particular feeding areas within the PCFG range. If prey is available in other areas in the PCFG range, hunting by the Makah Tribe might not result in either a short- or long-term response from summer-feeding whales. Also, because whales typically feed in shallower nearshore areas of the Makah U&A, the offshore location of hunting activities under Alternative 3 might result in little or no change in whale distribution. Many new whales are seen in the PCFG range every year, and there is significant interchange among survey areas within this range. Thus, even if some whales do abandon the area as a result of hunting disturbance, new whales that had not previously been exposed to hunting might come into the area.

If hunting in the coastal portion of the Makah U&A did cause a change in distribution, it is likely that whales would shift to using adjacent areas—especially the Strait of Juan de Fuca portion of the Makah U&A and southern Vancouver Island—because those areas already have high rates of interchange with the proposed hunt area. Also, because hunting activities under Alternative 3 would end prior to the June through November feeding period, it is possible that PCFG whales might only temporarily avoid the coastal portion of the Makah U&A given that there would be 6 consecutive months with no hunting-related activities. It is also possible that PCFG whales would be less affected by hunting activities located further off shore from areas typically used by feeding whales. Scores of whales have been hunted and killed by Chukotka Natives over several years (Table 3-52), yet whales continue to be available for harvest, suggesting that hunt-related activities have not resulted in major changes in gray whale numbers, distribution, or habitat use in that area. Thus, available information indicates that, like Alternative 2, gray whale distribution and habitat use under Alternative 3 would not change appreciably compared to the No-action Alternative.

4.4.3.3.4 Change in Numbers of Gray Whales Using the Makah U&A and OR-SVI Survey Areas

Compared to the No-action Alternative, Alternative 3 would result in gray whales being hunted in the coastal portion of the Makah U&A, which is a subset of the OR-SVI survey region and situated within the migration corridor of the entire ENP herd of gray whales. Such hunting could reduce the numbers of gray whales in these areas during the summer feeding period, either as a result of whales being killed or as a result of feeding whales changing their distribution during the summer feeding period.

Change in Numbers as a Result of Whales Being Killed

As described in Subsection 4.1.3, Alternative 3 and Table 4-1, the current maximum number of OR-SVI or Makah U&A whales killed would be four per year. However, it is more likely that an average of 1.6 OR-SVI whales or 1.4 Makah U&A whales might actually be killed each year (or 9.4 and 8.4 over six years) given the presumed proportional presence of these whales in the proposed hunt area during March through May when the Tribe is most likely to hunt. There is no information available to discern whether the Makah U&A whales or OR-SVI whales would be more or less likely to be encountered in the offshore hunt area established under Alternative 3. Thus, a similar number of PCFG whales would be killed under Alternative 3 compared to Alternative 2.

For the reasons described above under Alternative 2 (Subsection 4.4.3.2.4, Change in Numbers of Gray Whales in the Makah U&A and OR-SVI Survey Areas, Change in Numbers as a Result of Change in Distribution of Feeding Whales), sighting data since 1996 demonstrate that many new whales are seen each year in the OR-SVI and Makah U&A areas, and of these whales, variable but large numbers are seen (or never seen) again. Based on the annual average number of newly seen whales in the Makah U&A and OR-SVI survey areas (14 and 24 whales, respectively), it is possible that if up to one Makah U&A or OR-SVI whale were removed under Alternative 3, it would be replaced with another Makah U&A or OR-SVI whale. In that case, Alternative 3 would not result in a decrease in the total number of gray whales using the Makah U&A and OR-SVI survey areas during the summer feeding period, compared to the No-action Alternative. There is nevertheless a possibility that hunting under Alternative 3 might reduce the total number of whales using the OR-SVI area and that reduction would be less than under Alternative 2. While an ongoing hunt could reduce the number of whales returning to the Makah U&A and OR-SVI areas, it seems likely that such whales would be replaced in subsequent years given that an average of 7 newly-seen Makah U&A whales and 13 newly-seen OR-SVI whales are seen again in a subsequent year. If the PCFG abundance decreases in the Makah U&A, OR-SVI, or PCFG area because new whales (that become returning whales) do not take the place of killed PCFG whales, the calculated PCFG mortality limit would decrease over time, further reducing the effects under this Alternative. As an additional comparison, using the most recent minimum abundance estimate of 190 OR-SVI whales, an Rmax of 6.2 percent, and a recovery factor of 0.5 (based on the 2022 SAR value for PCFG whales; Carretta et al. (2023)), a PBR of 2.9 OR-SVI whales was calculated. This value is greater than the number of Makah U&A or OR-SVI whales likely removed under this alternative.

Change in Numbers as a Result of Change in Distribution of Feeding Whales

During the likely hunting season (March through May) under Alternative 3, about 83 whales approached annually during hunt activities would be expected to be Makah U&A whales and 93 would be expected to be OR-SVI whales (Subsection 4.1.3, Alternative 3) (Table 4-6). Thus, of the 353 whales potentially approached, approximately 23 percent (on average) would be Makah U&A whales and 26 percent would be OR-SVI whales. Of the 36 whales potentially subjected to harpoon attempts, 8 would be expected to be Makah U&A whales and 9 would be expected to be OR-SVI whales (which is similar to the numbers of whales estimated under Alternative 2).

For the reasons described under Alternative 2 (Subsection 4.4.3.2.4, Change in Number of Gray Whales in the Makah U&A and OR-SVI Survey Areas; Change in Numbers as a Result of Change in Distribution of Feeding Whales), it is unclear what effect approaches and unsuccessful harpoon attempts would have on whale distribution. Whale response to approaches is likely to be temporary (minutes or hours), and Chukotkan hunters have approached, struck, and killed hundreds of gray whales over several years with no major changes apparent in gray whale numbers, distribution, or habitat use in that area. The availability of prey may be the factor most strongly affecting gray whale numbers in particular feeding areas within the PCFG range. If prey is available in the Makah U&A or OR-SVI, hunting by the Makah Tribe might not result in either a short- or long-term response from summer-feeding whales. Also, because whales typically feed in shallower nearshore areas of the Makah U&A, the offshore location of hunting activities under Alternative 3 might result in little or no change in whale distribution. Many new whales are seen in the Makah U&A and OR-SVI every year, and there is significant interchange with whales from other adjacent areas in the PCFG range. Thus, even if some whales do abandon the area as a result of hunting disturbance, new whales that had not previously been exposed to hunting might come into the area.

Change in Numbers - Summary

Compared to the No-action Alternative, in which no Makah U&A or OR-SVI whales are likely to be killed or disturbed by hunting, Alternative 3 represents a potential decrease in the number of whales using these survey areas during the summer period (especially if external recruits do not replace killed whales). While the same number of whales would be approached under Alternatives 2 and 3, slightly fewer whales would be subjected to harpoon attempts under Alternative 3, and these attempts would occur much further off shore from where Makah U&A and OR-SVI whales typically feed. As with Alternative 2, it is likely that the number of PCFG whales would decrease but any decrease would be less than under Alternative 2 as fewer PCFG whales would likely be killed under Alternative 3. As with Alternative 2, it is most likely that gray whales would continue using these survey areas during the

summer months because: (1) under Alternative 3, the PCFG mortality limit is similar to the bycatch formula limit under Alternative 2 (and the IWC analysis) and the IWC analysis shows that PCFG whales would remain viable with a Makah hunt; (2) the bycatch formula for Alternative 3 is more conservative than the formula under Alternative 2 because of its treatment of struck and lost whales and female whales (Table 4-1); (3) PCFG whales are dense and abundant in the OR-SVI area; (4) PCFG whales are highly mobile within the PCFG range; (5) there are many new and returning whales available to replace killed whales; (6) the bycatch limit for PCFG whales accounts for changes in PCFG whale numbers; and (7) gray whales continue to return in large numbers to feeding areas where scores are actively hunted and killed each year (i.e., waters around Chukotka), suggesting that hunting will not cause them to abandon the PCFG feeding area.

4.4.3.3.5 Welfare of Individual Whales

As discussed in Subsection 4.1, Introduction, the number of gray whales that might be harvested from the ENP stock under all alternatives, including Alternative 3, would not change. It would remain at the existing IWC catch limit of 980 whales in a 7-year period and no more than 140 whales in any one year. The difference is that under the No-action Alternative, the entire catch could be taken by Chukotka Natives, while under Alternative 3 the Makah Tribe could take up to 24 whales from the 980 catch limit.

A major difference between Alternative 3 and the No-action Alternative is in the number of gray whales that might be disturbed by vessel approaches and unsuccessful harpoon attempts. Assuming that Makah hunters could embark on hunting trips during 60 days per year, it is possible that 353 gray whales might be approached per year and 36 of those whales subjected to unsuccessful harpoon attempts (Subsection 4.1.3, Alternative 3) (Table 4-6). The number of whales approached does not include the number that might be approached by vessels other than those used by Makah hunters (e.g., protest, media, and enforcement vessels). Compared to Alternative 2, it is likely that such approaches could be reduced because fewer protest vessels (especially small watercraft such as jet skis) would attempt to venture 5 miles (8 km) off shore under Alternative 3. Some of the whales subjected to approaches or unsuccessful harpoon attempts could be subsequently encountered during a hunt by Chukotkan Natives (which would typically occur during the summer and fall months), so there is a greater potential for increased disturbance under Alternative 3 compared to the No-action Alternative. However, this increased risk is extremely low; the high ENP abundance reduces the likelihood that an individual whale will encounter both Makah and Chukotkan hunters. In addition, an unsuccessful harpoon attempt—the most severe form of disturbance aside from struck and lost whales—would still

be limited to 36 whales, which is a very small fraction (0.2 percent) of the entire ENP stock and roughly the same level of impact as Alternative 2.

Like Alternative 2, the proportion of whales struck and lost could be greater in a Makah hunt under Alternative 3 than a Chukotka Native hunt under the No-action Alternative because the Chukotka Natives have more recent hunting experience. In recent years, the Chukotka Natives report that one percent of the whales struck in their hunt are lost. It is not possible to predict the proportion of whales that would be struck and lost in a Makah hunt under Alternative 3, but this alternative includes a potential of two whales struck and lost for four whales harvested before the 6-strike limit would be reached. The proportion of whales struck and lost under Alternative 3 could also be greater than the proportion in a Chukotka Native hunt because seasonal restrictions on the Makah hunt and the requirement under Alternative 3 to hunt at least 5 miles (8 km) from shore could result in hunts occurring in rough weather and sea conditions. Hunting under unfavorable conditions could reduce the accuracy of the hunters and make it more difficult to successfully land a killed whale (thus increasing the proportion of whales struck and lost).

Whales killed with a rifle in a Makah hunt under Alternative 3 could experience a shorter time to death than whales killed with a rifle in a Chukotka Native hunt because of the requirements proposed by the Makah (such as minimum visibility) and because the Makah would use a higher caliber killing weapon than the Chukotka Natives use. Whales killed with an explosive grenade(s) in either hunt would likely experience a similar time to death. Thus, a whale's time to death under Alternative 3 would be the same as under Alternative 2 and the same, if the hunt limits are transferred to Russia, or less compared to the No-action Alternative.

4.4.3.4 Alternative 4, Summer/Fall Hunt

Alternative 4 would have the same conditions as Alternative 2 regarding the hunt area (coastal portion of the Makah U&A, including the provision to not strike a whale within 200 yards (183 m) of Tatoosh Island and White Rock), the hunting methods, and regulatory framework. In contrast to Alternatives 2 and 3, Alternative 4 would have a different hunting season that is restricted to summer/fall months to avoid times when WNP whales might be encountered and would require hunters to approach only known ENP males. Like Alternative 3, Alternative 4 would differ from Alternative 2 in that it would include a limit on the total mortality (including struck and lost) of PCFG whales (0.76 whales/year, using current estimates; see Table 4-7). Under Alternative 4 and current conditions, the maximum number of whales that could be killed per year by the Tribe would be one whale every other year so as not to exceed the mortality limit. Unused portions of the PCFG mortality limit would not carry over to a subsequent year, unless the mortality limit is less than 1 but greater than 0.5 for 2 consecutive years. In this case, it would be aggregated to allow

for the mortality of one PCFG whale during the second year. During any 6-year period, up to three whales might be harvested, with three struck and three struck and lost. As many as 29 whales may be approached by whale hunting vessels in a hunt year and up to three whales may be exposed to unsuccessful harpoon attempts. With just one whale likely being harvested every other year, there could be up to 16 rifle shots fired or 3 grenade explosions every other year.

4.4.3.4.1 Change in Abundance and Viability of the ENP Gray Whale Stock

Like Alternatives 2 and 3, the potential direct and indirect mortality resulting from a whale hunt and hunt-related activities under Alternative 4 would be unlikely to change ENP gray whale stock abundance or viability compared to the No-action Alternative. As noted in Subsection 4.1, Introduction, the catch limit for the ENP gray whale stock set by the IWC would not change under this or any of the alternatives; thus, the same number of ENP gray whales would likely be harvested over 6 years under Alternative 4 as under the No-action Alternative. If a Makah hunt for three whales over 6 years resulted in a higher level of stress-related impacts than would occur if those three whales were harvested in a Chukotkan hunt under the No-action Alternative, the difference is unlikely to have an appreciable effect on the abundance and viability of the ENP gray whale stock as a whole. This is because the stress-related impacts associated with harvesting three whales over 6 years is likely to be minor in the context of the existing Chukotkan harvest level of 840 whales over 6 years.

If under the No-action Alternative the United States did not transfer unused portions of the catch limit to Russia, Alternative 4 would represent an increase in mortality of at most one gray whale over the 2 remaining years of the catch limit (2024 to 2025) (one struck whale every other year) compared to the No-action Alternative. Because one whale is a tiny fraction of the overall ENP gray whale stock (less than 0.01 percent), the increase in mortalities under Alternative 4 would be extremely unlikely to affect gray whale viability compared to the No-action Alternative.

If PCFG whales are uniquely adapted to exploit feeding areas in the southern portion of the ENP summer range, and that adaptation were lost if the PCFG were compromised, Alternative 4 has the potential to affect the long-term viability of the ENP stock as a whole. However, as described in Subsection 4.4.3.2.3, Change in Abundance and Viability of PCFG Whales, the best available information indicates that the PCFG would still be viable with a hunt under Alternative 4, so there is no reason to believe that this alternative would have deleterious impacts on the ENP stock as a whole.

4.4.3.4.2 Change in Abundance and Viability of the WNP Gray Whale Stock

Available sighting data (Subsection 3.4.3.2.1, WNP Seasonal Distribution, Migration, and Movements) indicate that WNP whales would not be encountered in the vicinity of the Makah U&A during the June through November hunt period considered under Alternative 4. Therefore, Alternative 4 would result in

less risk to WNP gray whales than Alternatives 2 and 3 and about the same risk as under the No-action Alternative. In the unlikely event that a WNP whale was encountered, regulations governing a hunt could require a suspension of the hunt if a WNP whale were killed. Procedures for photographing any whale that is landed would make it likely a WNP whale would be identified if it were landed. If a WNP whale were struck and lost, it is possible though not certain, it could be identified.

4.4.3.4.3 Change in Abundance and Viability of PCFG Whales

Compared to the No-action Alternative, Alternative 4 could reduce the abundance of PCFG gray whales, which could potentially affect the viability of the PCFG.

As described in Subsection 4.1.4, Alternative 4 and Table 4-1, the potential number of PCFG whales killed under Alternative 4 would be determined by the PCFG limit, which would be one whale every other year under current conditions.[13] The annual average harvest of one whale every other year under Alternative 4 is roughly one-third that expected under Alternative 3 and roughly one-quarter that expected under Alternative 2.

If one PCFG whale were killed every other year, it would represent a 0.2 percent reduction in the current abundance estimate of 212 PCFG whales (Harris et al. 2022). Compared to the No-action Alternative, this would represent a small decrease in abundance during the year in which PCFG whales were removed. Over time, it is uncertain whether or to what extent the death of one PCFG whale every other year might decrease the abundance of the PCFG whales. During the years 2008 to 2017, there were 12.3 new recruits on average, 7.9 (64 percent) of which were not identified as calves (Calambokidis et al. 2019). At the current rate of recruitment, the PCFG abundance trend appears to be stable. It is possible that external recruits could increase, compared to the No-action Alternative, as a result of the removal of one PCFG whale, in which case the abundance of the PCFG could remain at its current level.

In contrast to the No-action Alternative, Alternative 4 could reduce the numbers of PCFG whales and potentially affect the PCFG's viability. As described above, the reduction under Alternative 4 would be the same as under Alternative 3 and about one-third that expected under Alternative 2. The IWC Scientific Committee's analysis suggests the PCFG would remain viable with a hunt under Alternative 4. As described in Subsection 4.4.2.3, Change in Abundance and Viability of PCFG Whales, the IWC's Scientific Committee evaluated the Makah hunt proposal (Alternative 2) using models with a 100-year time horizon. That committee's conclusion indicates that the PCFG would be viable as long as the hunt

[13] Because Alternative 4, like Alternative 2, would allow seven strikes per year, the number of ENP whales potentially killed could be as high as seven, but this would require the PCFG abundance to more than triple, which is highly unlikely.

included a bycatch formula to limit the strikes on PCFG whales and annual monitoring was conducted to assess the availability of PCFG whales in the Makah hunt. The committee's modeling used a bycatch formula that, under population parameters at the time, yielded a bycatch limit of 3.0 PCFG whales per year. That value is much greater than the number of PCFG whales likely to be killed under Alternative 4 (i.e., one whale every two years), which includes a PCFG mortality limit that is more restrictive than the bycatch formula in Alternative 2 and the IWC analysis, indicating that the PCFG would still be viable with a hunt under Alternative 4. If the requisite monitoring indicated a higher availability of PCFG whales, then the IWC would likely reassess its conclusions via a new implementation review (Subsection 3.4.3.4.4, PCFG Status, Carrying Capacity, and Related Estimates; IWC Implementation Review of PCFG Gray Whales). Currently, it is thought that whales have two means of recruiting into the PCFG: either a whale learns to feed within the PCFG range from its mother or it immigrates to the PCFG from the larger ENP population later in its life. Alternative 4 is less likely to affect PCFG viability into the future as compared to Alternatives 2 and 3 because the hunt would target males and, thus, would not affect matrilineal recruitment. For the reasons described under Alternative 2 (Subsection 4.4.3.2.3, Change in Abundance and Viability of PCFG Gray Whales), it is unclear how whale distribution would be affected by hunt-related approaches and unsuccessful harpoon attempts. Whale response to approaches is likely to be temporary (minutes or hours), and Chukotkan hunters have approached, struck, and killed scores of gray whales over several years with no major changes apparent in whale numbers, distribution, or habitat use in that area. The availability of prey may be the factor most strongly affecting gray whale numbers in particular feeding areas within the PCFG range. If prey is available in other areas in the PCFG range, hunting by the Makah Tribe might not result in either a short- or long-term response from summer-feeding whales. Many new whales are seen in the PCFG range every year, and there is significant interchange among survey areas within this range. Thus, even if some whales do abandon the area as a result of hunting disturbance, new whales that had not previously been exposed to hunting might come into the area.

If hunting in the coastal portion of the Makah U&A did cause a change in distribution, it is likely that whales would shift to using adjacent areas—especially the Strait of Juan de Fuca portion of the Makah U&A and southern Vancouver Island—because those areas already have high rates of interchange with the proposed hunt area. Although hunting activities under Alternative 4 would occur during the June through November feeding period, it is possible that PCFG whales might only temporarily avoid the coastal portion of the Makah U&A because: (1) hunting would likely occur on just 7 days (i.e., less than 4 percent of the entire summer/fall feeding period), (2) this alternative has the lowest number of whales likely approached (29) of all the action alternatives, and (3) only a single male whale could be struck. Scores of whales have been hunted and killed by Chukotka Natives over several years (Table 3-

52), yet whales continue to be available for harvest, suggesting that hunt-related activities have not resulted in major changes in gray whale numbers, distribution, or habitat use in that area. Thus, available information indicates that, like Alternatives 2 and 3, gray whale distribution and habitat use under Alternative 4 would not change appreciably compared to the No-action Alternative.

4.4.3.4.4 Change in Numbers of Gray Whales Using the Makah U&A and OR-SVI Survey Areas

Compared to the No-action Alternative, Alternative 4 would result in gray whales being hunted in the coastal portion of the Makah U&A, which is a subset of the OR-SVI survey region and situated within the migration corridor of the entire ENP herd of gray whales. Such hunting could reduce the numbers of gray whales in these areas during the summer feeding period either as a result of whales being killed or as a result of feeding whales changing their distribution during the summer feeding period.

Change in Numbers as a Result of Whales Being Killed

As described in Subsection 4.1.4, Alternative 4 and Table 4-1, both the current maximum and likely number of OR-SVI or Makah U&A whales killed would be approximately one every two years (three whales from either area over 6 years). Under Alternative 4, all killed whales would be Makah U&A and OR-SVI whales by definition as the hunt would take place during the summer feeding period for PCFG whales. The likely number of these whales killed is about one-third that expected under Alternative 3 and roughly one-quarter that expected under Alternative 2.

For the reasons described above under Alternative 2, sighting data since 1996 demonstrate that many new whales are seen each year in the OR-SVI and Makah U&A areas, and of these whales, variable but large numbers are seen (or never seen) again. Based on the annual average number of newly seen whales in the Makah U&A and OR-SVI survey areas (14 and 24 whales, respectively), it is possible that if up to one Makah U&A or OR-SVI whale were removed under Alternative 4 every two years, it would be replaced with another Makah U&A or OR-SVI whale. In that case, Alternative 4 would not result in a decrease in the total number of gray whales using the Makah U&A and OR-SVI survey areas during the summer feeding period, compared to the No-action Alternative. There is nevertheless a possibility that hunting under Alternative 4 might reduce the total number of whales using the OR-SVI area, and that reduction would be less than under both Alternatives 2 and 3. If that reduction occurred, the minimum abundance estimate for PCFG whales would decline, causing a decrease in the calculated PCFG mortality limit under Alternative 4. Also, while an ongoing hunt could reduce the number of whales returning to the Makah U&A and OR-SVI areas, it seems likely that such whales would be replaced in subsequent years given that an average of 7 newly-seen Makah U&A whales and 13 newly-seen OR-SVI whales are seen again in a subsequent year. If for some reason new whales (that become

returning whales) did not take the place of killed returning whales in subsequent years, the calculated PCFG mortality limit would decrease over time as well. As an additional comparison, using the most recent minimum abundance estimate of 190 OR-SVI whales, an Rmax of 6.2 percent, and a recovery factor of 0.5 (based on the 2022 SAR value for PCFG whales; Carretta et al. (2023)), a PBR of 2.9 OR-SVI whales was calculated. This value is more than double the number of Makah U&A or OR-SVI whales likely removed under this alternative.

Change in Numbers as a Result of Change in Distribution of Feeding Whales

Under Alternative 4, about 29 whales would be approached annually during hunt activities (Subsection 4.1.4, Alternative 4) (Table 4-8) ,and all would be expected to be Makah U&A and OR-SVI whales because of the hunt taking place during the summer feeding period for PCFG whales. For the same reason, all of the three whales potentially subjected to harpoon attempts would be Makah U&A and OR-SVI whales. This number of whales is roughly half that expected under Alternatives 2 and 3.

For the reasons described under Alternative 2, it is unclear what effect approaches and unsuccessful harpoon attempts would have on whale distribution. Whale response to approaches is likely to be temporary (minutes or hours), and Chukotkan hunters have approached, struck, and killed hundreds of gray whales over several years with no major changes apparent in gray whale numbers, distribution, or habitat use in that area. The availability of prey may be the factor most strongly affecting gray whale numbers in particular feeding areas within the PCFG range. If prey is available in the Makah U&A or OR-SVI, hunting by the Makah Tribe might not result in either a short- or long-term response from summer-feeding whales. Also, many new whales are seen in the Makah U&A and OR-SVI every year, and there is significant interchange with whales from other adjacent areas in the PCFG range. Thus, even if some whales do abandon the area as a result of hunting disturbance, new whales that had not previously been exposed to hunting might come into the area.

Change in Numbers - Summary

Compared to the No-action Alternative, in which no Makah U&A or OR-SVI whales are likely to be killed by hunting, Alternative 4 represents a potential decrease in the number of whales using these survey areas during the summer period (especially if external recruits do not replace killed whales). Alternative 4 would result in roughly one-third the number of whales approached as under Alternatives 2 and 3, with the number of harpoon attempts being roughly one-third to one-quarter the number of attempts under Alternatives 2 and 3 (but note that Alternative 4 is less likely to be in offshore waters compared to Alternative 3). As with Alternatives 2 and 3, it is likely that the number of whales would decrease, although any decrease would be less than under Alternatives 2 or 3 because fewer PCFG whales would likely be killed under Alternative 4 than under Alternatives 2 or 3. As with Alternatives 2

and 3, it is most likely that gray whales would continue using these survey areas during the summer months because: (1) under Alternative 4, the PCFG mortality limit is more restrictive than the bycatch formula used in Alternative 2 (and the IWC analysis) by using a lower recovery factor and subtracting other human-caused mortality (Table 4-1), and the IWC analysis shows that PCFG whales would remain viable with a Makah hunt; (2) PCFG whales are dense and abundant in the OR-SVI area; PCFG whales are highly mobile within the PCFG range; (3) there are many new and returning whales available to replace killed whales; and (4) gray whales continue to return in large numbers to feeding areas where scores are actively hunted and killed each year (i.e., waters around Chukotka), suggesting that hunting will not cause them to abandon the PCFG feeding area. Furthermore, hunting only males ensures that internal recruitment of PCFG whales would not be affected by the hunt.

4.4.3.4.5 Welfare of Individual Whales

As discussed in Subsection 4.1.1.3, Potential Number of ENP and PCFG Whales Killed, the number of gray whales that might be harvested from the ENP stock under all alternatives, including Alternative 4 and the No-action Alternative, would not change. It would remain at the existing IWC catch limit of 980 whales in a 7-year period, and no more than 140 whales in any one year. The difference is that under the No-action Alternative, the entire catch could be taken by Chukotka Natives, while under Alternative 4 the Makah Tribe could take up to 24 whales from the 980 catch limit.

A major difference between Alternative 4 and the No-action Alternative is in the number of gray whales that might be disturbed by vessel approaches and unsuccessful harpoon attempts. Assuming that Makah hunters could embark on hunting trips during 7 days every other year, it is possible that an average of 29 gray whales might be approached every year and three of those whales subjected to unsuccessful harpoon attempts (Subsection 4.1.4, Alternative 4) (Table 4-8). The number of whales approached does not include the number that might be approached by vessels other than those used by Makah hunters. These impacts would be substantially lower overall than those expected under Alternatives 2 and 3. However, because the hunt under Alternative 4 is restricted to the summer and fall months and hunters may strike only known males, it is much more likely that impacts would be focused on PCFG whales.

Some of the whales subjected to approaches or unsuccessful harpoon attempts could be encountered during a hunt by Chukotkan Natives. Such encounters would most likely occur in a different year because the Makah Tribe's hunt would occur during the months when whales are likely to remain within the PCFG range before migrating south. Some whales may return to feeding grounds further north in subsequent years. So while there is a greater potential for increased disturbance to individual whales under Alternative 4 compared to the No-action Alternative, such disturbance would likely be

minimal and attenuated given that it would be many months between the time a whale was pursued in the Makah U&A and then in the Chukotkan hunt area (or vice versa). Additionally, the high ENP abundance reduces the likelihood that an individual whale will encounter both Makah and Chukotkan hunters. An unsuccessful harpoon attempt—the most severe form of disturbance aside from struck-and-lost whales —would still be limited to three whales, which is a very small fraction (0.02 percent) of the entire ENP stock and roughly one-tenth the impact expected under Alternatives 2 and 3.

Like Alternatives 2 and 3, the proportion of whales struck and lost could be greater in a Makah hunt under Alternative 4 than a Chukotka Native hunt under the No-action Alternative because the Chukotka Natives have more recent hunting experience. In recent years, the Chukotka Natives report that one percent of the whales struck in their hunt are lost. It is not possible to predict the proportion of whales that would be struck and lost in a Makah hunt under Alternative 4, but given that only one whale could be struck every other year (under current conditions), the proportion would be either zero or 100 percent. Alternative 4 would also have a lower likelihood of hunters striking and losing a whale compared to Alternatives 2 and 3 because ocean conditions during the summer and fall hunting months proposed under Alternative 4 would make it easier to land a struck whale than the less favorable ocean conditions during the spring hunting months of Alternatives 2 and 3.

Whales killed with a rifle in a Makah hunt under Alternative 4 could experience a shorter time to death than whales killed with a rifle in a Chukotka Native hunt because of the requirements proposed by the Makah (such as minimum visibility) and because the Makah would use a higher caliber killing weapon than the Chukotka Natives use. Whales killed with an explosive grenade(s) in either hunt would likely experience a similar time to death. Thus, a whale's time to death under Alternative 4 would be the same as under Alternatives 2 and 3, and the same or less compared to the No-action Alternative.

4.4.3.5 Alternative 5, Split-season Hunt

Alternative 5 would have the same conditions as Alternative 2 regarding the hunt area, hunting methods, and regulatory framework. In contrast, Alternative 5 would have a split hunting season (December 1 through 21 and May 10 through 31) intended to avoid killing a WNP whale and to minimize the chance of killing a PCFG whale. Like Alternatives 3 and 4, Alternative 5 would differ from Alternative 2 in that it would include a limit (0.35 whales/year, using current estimates) on the total mortality—including struck and lost—of PCFG whales. If the limit represents less than one whale, it would be allowed to accumulate across years for the purposes of calculating how frequently a PCFG whale could be killed or struck and lost. Although this PCFG mortality limit would always be less than one whale, the Tribe could hunt in any year—including the first year—until they either kill a PCFG whale or strike and lose any whale. If either of those two outcomes occur, then the PCFG mortality limit would be applied to determine the number of

years the Tribe would need to take a hiatus from hunting (i.e., until the accumulated mortality limits add up to at least one whale). During any 6-year period, up to 24 whales might be harvested, with 24 struck and 3 struck and lost (given the limit of one struck-and-lost whale per year coupled with the calculated mortality limit on PCFG whales). As many as 122 whales may be approached by whale hunting vessels in any one year and up to 30 whales may be exposed to unsuccessful harpoon attempts. With just one whale likely being harvested each year, there could be up to 16 rifle shots fired or 3 grenade explosions per year.

4.4.3.5.1 Change in Abundance and Viability of the ENP Gray Whale Stock

Like Alternatives 2, 3, and 4, the potential direct and indirect mortality resulting from a whale hunt and hunt-related activities under Alternative 5 would be unlikely to change ENP gray whale stock abundance or viability compared to the No-action Alternative. As noted in Subsection 4.1, Introduction, the catch limit for the ENP gray whale stock set by the IWC would not change under this or any of the other alternatives; thus, the same number of ENP gray whales would likely be harvested over 6 years under Alternative 5 as under the No-action Alternative. If a Makah hunt for the maximum of 24 whales allowed under Alternative 5 over 6 years resulted in a higher level of stress-related impacts than would occur if those 24 whales were harvested in a Chukotkan hunt under the No-action Alternative, the difference is unlikely to have an appreciable effect on the abundance and viability of the ENP gray whale stock as a whole. This is because the stress-related impacts associated with harvesting 24 whales over 6 years is likely to be minor in the context of the existing Chukotkan harvest level of 840 whales over 6 years.

If under the No-action Alternative the United States did not transfer unused portions of the catch limit to Russia, Alternative 5 would represent an increase in mortality of at most 10 gray whales over the 2 remaining years of the catch limit (2024 to 2025) (five struck whales per year times 2 years) compared to the No-action Alternative. Because 10 whales are a tiny fraction of the overall ENP gray whale stock (0.069 percent), the increase in mortalities under Alternative 5 would be extremely unlikely to affect gray whale viability compared to the No-action Alternative.

If PCFG whales are uniquely adapted to exploit feeding areas in the southern portion of the ENP summer range, and that adaptation were lost if the PCFG were compromised, Alternative 5 has the potential to affect the long-term viability of the ENP stock as a whole. However, as described in Subsection 4.4.3.2.3, Change in Abundance and Viability of PCFG Whales, the best available information indicates that the PCFG would still be viable with a hunt under Alternative 5, so there is no reason to believe that this alternative would have deleterious impacts on the ENP stock as a whole.

4.4.3.5.2 Change in Abundance and Viability of the WNP Gray Whale Stock

There are very limited data for WNP whales in the action area, but the available sighting data indicate that WNP whales are unlikely to be encountered in the vicinity of the Makah U&A during the hunt periods in May and December considered under Alternative 5, based on the short hunt timeframe and the lack of WNP sightings during this time (Subsection 3.4.3.2.1, WNP Seasonal Distribution, Migration, and Movements). However, the data available for the hunt period is too sparse to verify that the risk of taking a WNP whale would be different from other time periods of the migratory season, and thus we have analyzed the risk of taking a WNP whale using the same model by Moore et al. (2023) used for Alternatives 2 and 3. Based on modeling by Moore et al. (2023) we estimate that between 0.98 and 1.5 WNP gray whales may be approached per year under Alternative 5. This assumes that all 353 training and hunting approaches are utilized annually, that each approach is made on a unique individual, and that all approaches are made during the winter and spring months when WNP gray whales may be present in the hunt area. It is unlikely that all of these assumptions will be met, therefore this is a precautionary estimate of the potential impacts to WNP gray whales under Alternative 5. Assuming that all harpoon attempts are made each year, between 0.24 and 0.36 WNP gray whales may be subjected to unsuccessful harpoon attempts annually (Table 4-10). Therefore, assuming that the availability of WNP whales is the same during the proposed hunt period as during the rest of the migratory season, Alternative 5 would result in increased risk to WNP gray whales compared to the No-action Alternative and Alternative 4, and slightly less risk than under Alternatives 2 and 3.

There is limited data on how whales would react to unsuccessful harpoon attempts, but the reaction may be similar to that observed in whales that are tagged or biopsied (i.e., ranging from a subtle to overt response resulting in a potential temporary change in behavior). Based on these observations, it is likely that any changes in gray whale behavior due to unsuccessful strike attempts or training harpoon throws would be short-term in nature and would not have lasting effects on the behavior of targeted or nearby whales such that they would begin to avoid vessels.

While the chances of killing a WNP whale are low, even over a 6-year period, the loss of WNP whales, particularly reproductive females, from this small stock could be a conservation concern depending on the number lost and the time period over which such losses occurred. To mitigate for the possibility of a Makah hunt killing a WNP whale, regulations governing a hunt could require a suspension of the hunt if a WNP whale were killed. Procedures for photographing any whale that is landed would make it likely a WNP whale would be identified if it were landed. If a WNP whale were struck and lost, it is possible, though not certain, it could be identified.

4.4.3.5.3 Change in Abundance and Viability of PCFG Whales

Compared to the No-action Alternative, Alternative 5 could reduce the abundance of PCFG gray whales, which could potentially affect the viability of the PCFG. As described in Subsection 4.1.5, Alternative 5 and Table 4-1, the current maximum number of PCFG whales that could be killed under Alternative 5 would be one whale per three years. However, it is more likely that an average of one PCFG whale per four years might actually be killed given the high proportion of non-PCFG whales present in the Makah U&A during the spring portion of the hunting season when the Tribe is most likely to hunt. The annual average number is approximately 46 percent lower than that expected under Alternative 3, and 86 percent lower than that expected under Alternative 2, and about half of that expected under Alternative 4.

If one PCFG whale were killed every four years (i.e., 0.25 whales per year) it would represent a 0.12 percent reduction in the current abundance estimate of 212 PCFG whales (Harris et al. 2022). Compared to the No-action Alternative, this would represent an extremely small decrease in abundance during the year in which PCFG whales were removed. This decrease would be at least an order of magnitude smaller than the decreases expected under Alternatives 2, 3, and 4. Over time, it is uncertain whether or to what extent the death of one PCFG whale per four years might decrease the abundance of the PCFG. During the years 2008 to 2017, there were 12.3 new recruits on average, 7.9 (64 percent) of which were not identified as calves (Calambokidis et al. 2019). At the current rate of recruitment, the PCFG abundance trend appears to be stable. It is possible that external recruits could increase, compared to the No-action Alternative, as a result of the removal of one PCFG whale every four years, in which case the abundance of the PCFG could remain at its current level.

In contrast to the No-action Alternative, Alternative 5 could reduce the numbers of PCFG whales and potentially affect the PCFG's viability. As described above, the reduction under Alternative 5 would be at least an order of magnitude smaller than the reduction expected under Alternatives 2, 3, and 4. The IWC Scientific Committee's analysis suggests the PCFG would remain viable with a hunt under Alternative 5. As described in Subsection 4.4.2.3, Change in Abundance and Viability of PCFG Whales, the IWC's Scientific Committee evaluated the Makah hunt proposal (Alternative 2) using models with a 100-year time horizon. The committee's conclusion indicates that the PCFG would be viable as long as the hunt included a bycatch formula to limit the strikes on PCFG whales and annual monitoring was conducted to assess availability of PCFG whales in the Makah hunt. The committee's modeling used a bycatch formula that, under population parameters at the time, yielded a bycatch limit of 3.0 PCFG whales per year. That value is much greater than the number of PCFG whales likely to be killed under Alternative 5 (i.e., 0.25 whales per year), which includes a PCFG mortality limit that is

more restrictive than the bycatch formula in Alternative 2 and the IWC analysis, indicating that the PCFG would still be viable with a hunt under Alternative 5. If the requisite monitoring indicated a higher availability of PCFG whales, then the IWC would likely reassess its conclusions via a new implementation review (Subsection 3.4.3.4.4, PCFG Status, Carrying Capacity, and Related Estimates; IWC Implementation Review of PCFG Gray Whales).

For the reasons described under Alternative 2, it is unclear how whale distribution would be affected by hunt-related approaches and unsuccessful harpoon attempts. Whale response to approaches is likely to be temporary (minutes or hours), and Chukotkan hunters have approached, struck, and killed scores of gray whales over several years with no major changes apparent in whale numbers, distribution, or habitat use in that area. The availability of prey may be the factor most strongly affecting gray whale numbers in particular feeding areas within the PCFG range. If prey is available in other areas in the PCFG range, hunting by the Makah Tribe might not result in either a short- or long-term response from summer-feeding whales. Many new whales are seen in the PCFG range every year and there is significant interchange among survey areas within this range. Thus, even if some whales do abandon the area as a result of hunting disturbance, new whales that had not previously been exposed to hunting might come into the area.

If hunting in the coastal portion of the Makah U&A did cause a change in distribution, it is likely that whales would shift to using adjacent areas—especially the Strait of Juan de Fuca portion of the Makah U&A and southern Vancouver Island—because those areas already have high rates of interchange with the proposed hunt area. Also, because hunting activities under Alternative 5 would end prior to the June through November feeding period, it is possible that PCFG whales might only temporarily avoid the coastal portion of the Makah U&A given that there would be 6 consecutive months with no hunting-related activities. It is also possible that PCFG whales would be less affected by hunting activities that are limited to 11 days per year outside the time when PCFG whales typically feed in the hunt area. Scores of whales have been hunted and killed by Chukotka Natives over several years (Table 3-52), yet whales continue to be available for harvest, suggesting that hunt-related activities have not resulted in major changes in gray whale numbers, distribution, or habitat use in that area. Thus, available information indicates that, like Alternatives 2, 3, and 4, gray whale distribution and habitat use under Alternative 5 would not change appreciably compared to the No-action Alternative.

4.4.3.5.4 Change in Numbers of Gray Whales Using the Makah U&A and OR-SVI Survey Areas

Compared to the No-action Alternative, Alternative 5 would result in gray whales being hunted in the coastal portion of the Makah U&A, which is a subset of the OR-SVI survey region and situated within

the migration corridor of the entire ENP herd of gray whales. Such hunting could reduce the numbers of gray whales in these areas during the summer feeding period either as a result of whales being killed or as a result of feeding whales changing their distribution during the summer feeding period.

Change in Numbers as a Result of Whales Being Killed

As described in Subsection 4.1.5, Alternative 5 and Table 4-1, the current maximum number of OR-SVI or Makah U&A whales killed would be one per year. However, it is more likely that an average of one OR-SVI whale or one Makah U&A whale might actually be killed every four years given the presumed proportional presence of these whales in the proposed hunt area during the May time period when the Tribe is most likely to hunt. The likely number of these whales killed (approximately 0.24 and 0.21 whales per year, respectively) is much lower than the one to two whales likely killed each year under Alternatives 2 and 3, and the average of 0.5 whales likely killed per year under Alternative 4.

For the reasons described above under Alternative 2, sighting data since 1996 demonstrate that many new whales are seen each year in the OR-SVI and Makah U&A areas, and of these whales, variable but large numbers are seen (or never seen) again. Based on the annual average number of newly seen whales in the Makah U&A and OR-SVI survey areas (14 and 24 whales, respectively), it is very likely that if one Makah U&A or OR-SVI whale were removed every four years under Alternative 5, it would be replaced with another Makah U&A or OR-SVI whale. In that case, Alternative 5 would not result in a decrease in the total number of gray whales using the Makah U&A and OR-SVI survey areas during the summer feeding period, compared to the No-action Alternative. There is nevertheless a possibility that hunting under Alternative 5 might reduce the total number of whales using the OR-SVI area, and that reduction would be much less than under Alternatives 2, 3, and 4. If that reduction occurred, the minimum abundance estimate for PCFG whales could decline, causing a decrease in the calculated PCFG mortality limit under Alternative 5. Also, while an ongoing hunt could reduce the number of whales returning to the Makah U&A and OR-SVI areas, it seems likely that such whales would be replaced in subsequent years given that an average of 7 newly-seen Makah U&A whales and 13 newly-seen OR-SVI whales are seen again in a subsequent year. If for some reason new whales (that become returning whales) did not take the place of killed returning whales in subsequent years, the calculated PCFG mortality limit would decrease over time as well. As an additional comparison, using the most recent minimum abundance estimate of 190 OR-SVI whales, an Rmax of 6.2 percent, and a recovery factor of 0.5 (based on the 2022 SAR value for PCFG whales; Carretta et al. (2023)), a PBR of 2.9 OR-SVI whales was calculated. This value is more than 12 times greater than the number of Makah U&A or OR-SVI whales likely removed under this alternative.

Change in Numbers as a Result of Change in Distribution of Feeding Whales

During the split hunting season (3 weeks each in May and December) under Alternative 5, annually about 29 whales approached during hunt activities would be expected to be Makah U&A whales, while 32 would be expected to be OR-SVI whales (Subsection 4.1.5, Alternative 5) (Table 4-10). Thus, of the 122 whales potentially approached, approximately 23 percent (on average) would be Makah U&A whales and 26 percent would be OR-SVI whales. Of the 30 whales potentially subjected to harpoon attempts, 1.2 would be expected to be a Makah U&A whale and 1.4 would be expected to be OR-SVI whales. These numbers are roughly one-third to one-half of those expected under Alternative 4, and are substantially lower than the 8 to 11 whales expected under Alternatives 2 and 3.

For the reasons described under Alternative 2, it is unclear what effect approaches and unsuccessful harpoon attempts would have on whale distribution. Whale response to approaches is likely to be temporary (minutes or hours), and Chukotkan hunters have approached, struck, and killed hundreds of gray whales over several years with no major changes apparent in gray whale numbers, distribution, or habitat use in that area. The availability of prey may be the factor most strongly affecting gray whale numbers in particular feeding areas within the PCFG range. If prey is available in the Makah U&A or OR-SVI, hunting by the Makah Tribe might not result in either a short- or long-term response from summer-feeding whales. Also, many new whales are seen in the Makah U&A and OR-SVI every year and there is significant interchange with whales from other adjacent areas in the PCFG range. Thus, even if some whales do abandon the area as a result of hunting disturbance, new whales that had not previously been exposed to hunting might come into the area.

Change in Numbers - Summary

Compared to the No-action Alternative, in which no Makah U&A or OR-SVI whales are likely to be killed by hunting, Alternative 5 represents a potential decrease in the number of whales using these survey areas during the summer period (especially if external recruits do not replace killed whales). The 32 to 33 whales approached under Alternative 5 would be roughly 65 percent lower than the number approached under Alternatives 2 and 3, while the number of harpoon attempts under Alternative 5 would be 81 to 97 percent lower, a substantial decrease. Under current conditions, the number of whales approached under Alternatives 4 and 5 would be similar, however almost twice as many OR-SVI and Makah U&A whales would be subjected to unsuccessful strike attempts under Alternative 4 as Alternative 5, on average. As with Alternatives 2, 3, and 4, it is likely that the number of PCFG whales would decrease, although any decrease would be less than under Alternatives 2, 3, and 4 because fewer PCFG whales would likely be killed under Alternative 5 than under Alternatives 2, 3, and 4. Under Alternative 5, the number of PCFG whales killed would be so small (0.25 per year) that

the removal of whales would be unlikely to have an effect on the number of whales in the Makah U&A and OR-SVI survey areas over time.

As with Alternatives 2, 3, and 4, it is most likely that gray whales would continue using these survey areas during the summer months because: (1) under Alternative 5, the PCFG mortality limit is more restrictive than the bycatch formula used in Alternative 2 (and the IWC analysis) by its treatment of struck and lost whales (Table 4-1), and the IWC analysis shows that PCFG whales would remain viable with a Makah hunt; (2) PCFG whales are dense and abundant in the OR-SVI area; (3) PCFG whales are highly mobile within the PCFG range; (4) there are many new and returning whales available to replace killed whales; and (5) gray whales continue to return in large numbers to feeding areas where scores are actively hunted and killed each year (i.e., waters around Chukotka), suggesting that hunting will not cause them to abandon the PCFG feeding area.

4.4.3.5.5 Welfare of Individual Whales

As discussed in Subsection 4.1, Introduction, the number of gray whales that might be harvested from the ENP stock under all alternatives, including Alternative 5 and the No-action Alternative, would not change. It would remain at the existing IWC catch limit of 980 whales in a 7-year period and no more than 140 whales in any one year. The difference is that under the No-action Alternative, the entire catch could be taken by Chukotka Natives, while under Alternative 5 the Makah Tribe could take up to 24 whales from the 980 catch limit.

A major difference between Alternative 5 and the No-action Alternative is in the number of gray whales that might be disturbed by vessel approaches and unsuccessful harpoon attempts. Assuming that Makah hunters could embark on hunting trips during 22 days per year, it is possible that 122 gray whales might be approached per year and 30 of those whales subjected to unsuccessful harpoon attempts (Subsection 4.1.5, Alternative 5) (Table 4-10). The number of whales approached does not include the number that might be approached by vessels other than those used by Makah hunters. Some of the whales approached could be subsequently encountered during a hunt by Chukotkan Natives (which typically occur during the summer and fall months), so there is a greater potential for increased disturbance under Alternative 5 compared to the No-action Alternative. However, this increased risk is extremely low; the high ENP abundance reduces the likelihood that an individual whale will encounter both Makah and Chukotkan hunters. In addition, an unsuccessful harpoon attempt—the most severe form of disturbance aside from struck-and-lost whales—would still be limited to 30 whales, which is a very small fraction (0.2 percent) of the entire ENP stock. This would result in roughly the same level of impact as Alternatives 2 and 3, but approximately 10 times the impact expected under Alternative 4.

Like Alternatives 2, 3, and 4, the proportion of whales struck and lost could be greater in a Makah hunt under Alternative 5 than a Chukotka Native hunt under the No-action Alternative because the Chukotka Natives have more recent hunting experience. In recent years, the Chukotka Natives report that one percent of the whales struck in their hunt are lost. It is not possible to predict the proportion of whales that would be struck and lost in a Makah hunt under Alternative 5, but this alternative includes a potential of one whale struck and lost for four whales harvested. The proportion of whales struck and lost under Alternative 5 could also be greater than the proportion in a Chukotka Native hunt because seasonal restrictions on the Makah hunt under Alternative 5 could result in hunts occurring in rough weather and sea conditions. Hunting under unfavorable conditions could reduce the accuracy of the hunters and make it more difficult to successfully land a killed whale (thus increasing the proportion of whales struck and lost).

Whales killed with a rifle in a Makah hunt under Alternative 5 could experience a shorter time to death than whales killed with a rifle in a Chukotka Native hunt because of the requirements proposed by the Makah (such as minimum visibility) and because the Makah would use a higher caliber killing weapon than the Chukotka Natives use. Whales killed with an explosive grenade(s) in either hunt would likely experience a similar time to death. Thus, a whale's time to death under Alternative 5 would be the same as under Alternatives 2, 3, and 4, and the same or less compared to the No-action Alternative.

4.4.3.6 Alternative 6, Different Limits on Strikes and PCFG, and Limited Duration of Regulations and Permits

Alternative 6 would have the same conditions as Alternative 2 regarding the hunt area (coastal portion of the Tribe's U&A), hunting season (December 1 through May 31) and hunting methods. In contrast to Alternative 2, Alternative 6 would have different limits on strikes. Under Alternative 2, there would be a limit of seven strikes per year, while under Alternative 6 there would be a limit of 7 strikes over a 2-year period, or 3.5 strikes per year on average. Also, under Alternative 6, a harvested whale would only count against the PCFG limit if it met the definition of a PCFG whale (i.e., it was sighted in at least 2 years in the PCFG seasonal range). Like Alternatives 3, 4, and 5, Alternative 6 would differ from Alternative 2 in that it would include a limit on the total mortality—including struck and lost—of PCFG whales (1.8 whales/year, using current estimates). The maximum number of whales that could be killed would be four in a single year, seven over 2 years, and 3.5 per year on average. During any 6-year period, up to 21 whales might be harvested, struck, or struck and lost. For this analysis, we assume that whales that are struck will die. As many as 353 whales may be approached by whale hunting vessels in any one year and up to 21 whales may be exposed to unsuccessful harpoon attempts. With an annual average of up to 3.5 whales likely being harvested, there could be up to 56 rifle shots fired or 11 grenade explosions per year. Given the limited number of likely hunting days available under Alternative 6, the Tribe might

not be able to harvest the full number of whales allowed. Finally, Alternative 6 would differ from Alternative 2 in the regulatory regime adopted, in particular the waiver of the take moratorium and implementing regulations would last only 10 years and permits would be issued for a shorter term (3 years instead of 5). It is not possible to predict whether they would be replaced with a new waiver, regulations, and permits or what, if any, the new terms would be. Therefore, the analysis for Alternative 6 considers hunt activities lasting only over a 10-year period.

4.4.3.6.1 Change in Abundance and Viability of the ENP Gray Whale Stock

Like Alternatives 2 through 5, the potential direct and indirect mortality resulting from a whale hunt and hunt-related activities under Alternative 6 would be unlikely to change ENP gray whale stock abundance or viability compared to the No-action Alternative. As noted in Subsection 4.1, Introduction, the catch limit for the ENP gray whale stock set by the IWC would not change under this or any of the other alternatives; thus, the same number of ENP gray whales would likely be harvested over 6 years under Alternative 6 as under the No-action Alternative. If a Makah hunt for 21 whales over 6 years resulted in a higher level of stress-related impacts than would occur if those 21 whales were harvested in a Chukotkan hunt under the No-action Alternative, the difference is unlikely to have an appreciable effect on the abundance and viability of the ENP gray whale stock as a whole. This is because the stress-related impacts associated with harvesting 21 whales over 6 years is likely to be minor in the context of the existing Chukotkan harvest level of 840 whales over 6 years.

If under the No-action Alternative the United States did not transfer unused portions of the catch limit to Russia, Alternative 6 would represent an increase in mortality of at most 7 gray whales over the 2 remaining years of the catch limit (2024 to 2025) (3.5 struck whales per year times 2 years) compared to the No-action Alternative. Because 7 whales are a tiny fraction of the overall ENP gray whale stock (less than 0.1 percent), the increase in mortalities under Alternative 6 would be extremely unlikely to affect gray whale viability compared to the No-action Alternative.

If PCFG whales are uniquely adapted to exploit feeding areas in the southern portion of the ENP summer range, and that adaptation were lost if the PCFG were compromised, Alternative 6 has the potential to affect the long-term viability of the ENP stock as a whole. However, as described in Subsection 4.4.3.2.3, Change in Abundance and Viability of PCFG Whales, the best available information indicates that the PCFG would still be viable with a hunt under Alternative 6, so there is no reason to believe that this alternative would have deleterious impacts on the ENP stock as a whole.

4.4.3.6.2 Change in Abundance and Viability of the WNP Gray Whale Stock

There are very limited data for WNP whales in the action area, but the available sighting data (Subsection 3.4.3.2.1, WNP Seasonal Distribution, Migration, and Movements) suggest that WNP

whales could be encountered in the vicinity of the Makah U&A during much of the hunting season under Alternative 6, perhaps with the exception of early May to late December. Based on modeling inn Moore et al. (2023), the estimated risk of approaching WNP gray whales annually and over 6 years is the same as under Alternatives 2 and 3. Assuming that all harpoon attempts are made each year, between 0.17 and 0.25 WNP gray whales may be subjected to unsuccessful harpoon attempts annually (Table 4-12). Therefore, Alternative 6 would result in increased risk to WNP gray whales compared to the No-action Alternative and Alternative 4, and less risk (especially in terms of strikes and attempted strikes) compared to Alternatives 2, 3, and 5.

There is limited data on how whales would react to unsuccessful harpoon attempts, but the reaction may be similar to that observed in whales that are tagged or biopsied (i.e., ranging from a subtle to overt response resulting in a potential temporary change in behavior). Based on these observations, it is likely that any changes in gray whale behavior due to unsuccessful strike attempts or training harpoon throws would be short-term in nature and would not have lasting effects on the behavior of targeted or nearby whales such that they would begin to avoid vessels.

While the chances of killing a WNP whale are low, even over a 6-year period, the loss of WNP whales, particularly reproductive females, from this small stock could be a conservation concern depending on the number lost and the time period over which such losses occurred. To mitigate for the possibility of a Makah hunt killing a WNP whale, regulations governing a hunt could require a suspension of the hunt if a WNP whale were killed. Procedures for photographing any whale that is landed would make it likely a WNP whale would be identified if it were landed. If a WNP whale were struck and lost, it is possible, though not certain, it could be identified.

4.4.3.6.3 Change in Abundance and Viability of PCFG Whales

Compared to the No-action Alternative, Alternative 6 could reduce the abundance of PCFG gray whales, which could potentially affect the viability of the PCFG. As described in Subsection 4.1.6, Alternative 6 and Table 4-1, the current maximum number of PCFG whales that could be killed under Alternative 6 would be 3.5 whales per year. However, it is more likely that an average of 0.96 PCFG whale per year might actually be killed (and 5.7 whales over 6 years) given the high proportion of non-PCFG whales present in the Makah U&A during the spring portion of the hunting season when the Tribe is most likely to hunt. The annual average number is roughly one-half that expected under Alternatives 2 and 3, almost twice as Alternative 4, and almost 4 times higher than that expected under Alternative 5.

If one PCFG whale were killed in a year, it would represent a 0.5 percent reduction in the current abundance estimate of 212 PCFG whales (Harris et al. 2022). Compared to the No-action Alternative,

this would represent a small decrease in abundance during the year in which PCFG whales were removed. Over time, it is uncertain whether or to what extent the death of one PCFG whale per year might decrease the abundance of the PCFG. During the years 2008 to 2017, there were 12.3 new recruits on average, 7.9 (64 percent) of which were not identified as calves (Calambokidis et al. 2019). At the current rate of recruitment, the PCFG abundance trend appears to be stable. It is possible that external recruits could increase, compared to the No-action Alternative, as a result of the removal of one PCFG whale, in which case the abundance of the PCFG could remain at its current level.

In contrast to the No-action Alternative, Alternative 6 could reduce the numbers of PCFG whales and potentially affect the PCFG's viability. As described above, the reduction under Alternative 6 would be about half that expected under Alternative 2, the same as under Alternatives 3 and 4, and 7 times greater than under Alternative 5. The IWC Scientific Committee's analysis suggests the PCFG would remain viable with a hunt under Alternative 6. As described in Subsection 4.4.2.3, Change in Abundance and Viability of PCFG Whales, the IWC's Scientific Committee evaluated the Makah hunt proposal (Alternative 2) using models with a 100-year time horizon. The committee's conclusion indicates that the PCFG would be viable as long as the hunt included the Tribe's bycatch formula to limit the strikes on PCFG whales and annual monitoring was conducted to assess availability of PCFG whales in the Makah hunt. The committee's modeling used the Tribe's bycatch formula which, under population parameters at the time, yielded a bycatch limit of 3.0 PCFG whales per year. That value is much greater than the number of PCFG whales likely to be killed under Alternative 6 (i.e., one whale per year), which includes a PCFG mortality limit that is more restrictive than the bycatch formula in Alternative 2 and the IWC analysis, indicating that the PCFG would still be viable with a hunt under Alternative 6. If the requisite monitoring indicated a higher availability of PCFG whales, then the IWC would likely reassess its conclusions via a new implementation review (Subsection 3.4.3.4.4, PCFG Status, Carrying Capacity, and Related Estimates; IWC Implementation Review of PCFG Gray Whales).

For the reasons described under Alternative 2, it is unclear how whale distribution would be affected by hunt-related approaches and unsuccessful harpoon attempts. Whale response to approaches is likely to be temporary (minutes or hours), and Chukotkan hunters have approached, struck, and killed scores of gray whales over several years with no major changes apparent in whale numbers, distribution, or habitat use in that area. The availability of prey may be the factor most strongly affecting gray whale numbers in particular feeding areas within the PCFG range. If prey is available in other areas in the PCFG range, hunting by the Makah Tribe might not result in either a short- or long-term response from summer-feeding whales. Many new whales are seen in the PCFG range every year and there is

significant interchange among survey areas within this range. Thus, even if some whales do abandon the area as a result of hunting disturbance, new whales that had not previously been exposed to hunting might come into the area.

If hunting in the coastal portion of the Makah U&A did cause a change in distribution, it is likely that whales would shift to using adjacent areas—especially the Strait of Juan de Fuca portion of the Makah U&A and southern Vancouver Island—because those areas already have high rates of interchange with the proposed hunt area. Also, because hunting activities under Alternative 6 would end prior to the June through November feeding period, it is possible that PCFG whales might only temporarily avoid the coastal portion of the Makah U&A given that there would be 6 consecutive months with no hunting-related activities. Scores of whales have been hunted and killed by Chukotka Natives over several years (Table 3-52), yet whales continue to be available for harvest, suggesting that hunt-related activities have not resulted in major changes in gray whale numbers, distribution, or habitat use in that area. Thus, available information indicates that, like Alternatives 2 through 5, gray whale distribution and habitat use under Alternative 6 would not change appreciably compared to the No-action Alternative.

4.4.3.6.4 Change in Numbers of Gray Whales Using the Makah U&A and OR-SVI Survey Areas

Compared to the No-action Alternative, Alternative 6 would result in gray whales being hunted in the coastal portion of the Makah U&A, which is a subset of the OR-SVI survey region and situated within the migration corridor of the entire ENP herd of gray whales. Such hunting could reduce the numbers of gray whales in these areas during the summer feeding period either as a result of whales being killed or as a result of feeding whales changing their distribution during the summer feeding period.

Change in Numbers as a Result of Whales Being Killed

As described in Subsection 4.1.6, Alternative 6 and Table 4-12, the current maximum number of OR-SVI or Makah U&A whales killed would be 3.5 per year. However, it is more likely that an average of 0.92 OR-SVI whale or 0.82 Makah U&A whale might actually be killed each year given the presumed proportional presence of these whales in the proposed hunt area during the March through May time period when the Tribe is most likely to hunt. The likely number of these whales killed is approximately three to four times higher than those expected under Alternative 5, roughly twice those expected under Alternative 4, and about half the expected number under Alternatives 2 and 3.

For the reasons described above under Alternative 2, sighting data since 1996 demonstrate that many new whales are seen each year in the OR-SVI and Makah U&A areas, and of these whales, variable but large numbers are seen (or never seen) again. Based on the annual average number of newly seen whales in the Makah U&A and OR-SVI survey areas (14 and 24 whales, respectively), it is very likely

that if up to one Makah U&A or OR-SVI whale were removed every year under Alternative 6, it would be replaced with another Makah U&A or OR-SVI whale. In that case, Alternative 6 would not result in a decrease in the total number of gray whales using the Makah U&A and OR-SVI survey areas during the summer feeding period, compared to the No-action Alternative. There is nevertheless a possibility that hunting under Alternative 6 might reduce the total number of whales using the OR-SVI area. If that reduction occurred, the minimum abundance estimate for PCFG whales would decline, causing a decrease in the calculated PCFG mortality limit under Alternative 6. Also, while an ongoing hunt could reduce the number of whales returning to the Makah U&A and OR-SVI areas, it seems likely that such whales would be replaced in subsequent years given that an average of 7 newly-seen Makah U&A whales and 13 newly-seen OR-SVI whales are seen again in a subsequent year. If for some reason new whales (that become returning whales) did not take the place of killed returning whales in subsequent years, the calculated PCFG mortality limit would decrease over time as well. As an additional comparison, using the most recent minimum abundance estimate of 190 OR-SVI whales, an Rmax of 6.2 percent, and a recovery factor of 0.5 (based on the 2022 SAR value for PCFG whales; Carretta et al. (2023)), yielded a PBR of 2.9 OR-SVI whales. This value is more than triple the number of Makah U&A or OR-SVI whales likely removed under this alternative.

Change in Numbers as a Result of Change in Distribution of Feeding Whales

During the likely hunting season (March through May) under Alternative 6, annually about 83 whales approached during hunt activities would be expected to be Makah U&A whales, while 93 would be expected to be OR-SVI whales (Subsection 4.1.6, Alternative 6) (Table 4-12). Thus, of the 353 whales potentially approached, approximately 23 percent (on average) would be Makah U&A whales and 26 percent would be OR-SVI whales. Of the 21 whales potentially subjected to harpoon attempts, 4.9 would be expected to be Makah U&A whales and 5.5 would be expected to be OR-SVI whales. These numbers are approximately three to four times higher than those expected under Alternative 5, roughly the same as those expected under Alternative 4, and about half the expected number of harpoon attempts but the same number of approaches as under Alternatives 2 and 3.

For the reasons described under Alternative 2, it is unclear what effect approaches and unsuccessful harpoon attempts would have on whale distribution. Whale response to approaches is likely to be temporary (minutes or hours), and Chukotkan hunters have approached, struck, and killed hundreds of gray whales over several years with no major changes apparent in gray whale numbers, distribution, or habitat use in that area. The availability of prey may be the factor most strongly affecting gray whale numbers in particular feeding areas within the PCFG range. If prey is available in the Makah U&A or OR-SVI, hunting by the Makah Tribe might not result in either a short- or long-term response from

summer-feeding whales. Also, many new whales are seen in the Makah U&A and OR-SVI every year and there is significant interchange with whales from other adjacent areas in the PCFG range. Thus, even if some whales do abandon the area as a result of hunting disturbance, new whales that had not previously been exposed to hunting might come into the area.

Change in Numbers - Summary

Compared to the No-action Alternative in which no Makah U&A or OR-SVI whales are likely to be killed by hunting, Alternative 6 represents a potential decrease in the number of whales using these survey areas during the summer period (especially if external recruits do not replace killed whales). The number of whales approached (83 to 93) under Alternative 6 would be the same as under Alternatives 2 and 3, and much higher than the 29 to 32 whales expected under Alternatives 4 and 5. The number of OR-SVI and MUA whales subjected to harpoon attempts (5 to 6) under Alternative 6 would be twice as under Alternative 4, about half the number expected under Alternatives 2 and 3, and much higher than the number expected under Alternative 5. As with Alternatives 2 through 5, it is likely that the number of whales would decrease. As with Alternatives 2 through 5, it is most likely that gray whales would continue using these survey areas during the summer months because: under Alternative 6, the PCFG mortality limit is more restrictive than the bycatch formula used in Alternative 2 (and the IWC analysis) by its treatment of struck and lost whales and subtraction of human-caused mortality (Table 4-1), and the IWC analysis shows that PCFG whales would remain viable with a Makah hunt; PCFG whales are dense and abundant in the OR-SVI area; PCFG whales are highly mobile within the PCFG range; there are many new and returning whales available to replace killed whales; and gray whales continue to return in large numbers to feeding areas where scores are actively hunted and killed each year (i.e., waters around Chukotka), suggesting that hunting will not cause them to abandon the PCFG feeding area.

4.4.3.6.5 Welfare of Individual Whales

As discussed in Subsection 4.1, Introduction, the number of gray whales that might be harvested from the ENP stock under all alternatives, including Alternative 6 and the No-action Alternative, would not change. It would remain at the existing IWC catch limit of 980 whales in a 7-year period and no more than 140 whales in any one year. The difference is that under the No-action Alternative, the entire catch could be taken by Chukotka Natives, while under Alternative 2 the Makah Tribe could take up to 21 whales from the 980 catch limit.

A major difference between Alternative 6 and the No-action Alternative is in the number of gray whales that might be disturbed by vessel approaches and unsuccessful harpoon attempts. Assuming that Makah hunters could embark on hunting trips during 60 days per year, it is possible that 353 gray

whales might be approached per year and 21 of those whales subjected to unsuccessful harpoon attempts (Subsection 4.1.6, Alternative 6) (Table 4-12). The number of whales approached does not include the number that might be approached by vessels other than those used by Makah hunters. Some of the whales approached could be subsequently encountered during a hunt by Chukotkan Natives (which typically occur during the summer and fall months), so there is a greater potential for increased disturbance under Alternative 6 compared to the No-action Alternative. However, this increased risk is extremely low; the high ENP abundance reduces the likelihood that an individual whale will encounter both Makah and Chukotkan hunters. In addition, an unsuccessful harpoon attempt—the most severe form of disturbance aside from struck-and-lost whale—would still be limited to 21 whales, which is a very small fraction (0.1 percent) of the entire ENP stock. This would result in a smaller level of impact than Alternatives 2, 3, and 5 but approximately seven times the impact expected under Alternative 4.

Like Alternatives 2 through 5, the proportion of whales struck and lost could be greater in a Makah hunt under Alternative 6 than a Chukotka Native hunt under the No-action Alternative because the Chukotka Natives have more recent hunting experience. In recent years, the Chukotka Natives report that one of the whales struck in their hunt are lost. It is not possible to predict the proportion of whales that would be struck and lost in a Makah hunt under Alternative 6, but this alternative includes a potential of up to four whales harvested or struck and lost before the four-strike limit would be reached. The proportion of whales struck and lost under Alternative 6 could also be greater than the proportion in a Chukotka Native hunt because seasonal restrictions on the Makah hunt under Alternative 6 could result in hunts occurring in rough weather and sea conditions. Hunting under unfavorable conditions could reduce the accuracy of the hunters and make it more difficult to successfully land a killed whale (thus increasing the proportion of whales struck and lost).

Whales killed with a rifle in a Makah hunt under Alternative 6 could experience a shorter time to death than whales killed with a rifle in a Chukotka Native hunt because of the requirements proposed by the Makah (such as minimum visibility) and because the Makah would use a higher caliber killing weapon than the Chukotka Natives use. Whales killed with an explosive grenade(s) in either hunt would likely experience a similar time to death. Thus, a whale's time to death under Alternative 6 would be the same as under Alternatives 2 through 5, and the same or less compared to the No-action Alternative.

4.4.3.7 Alternative 7, Composite Alternative – Preferred

Alternative 7 contains many of the same provisions regarding hunt location and methods as the other action alternatives but differs in two key ways:

(1) It relies on an alternating-year hunt schedule whereby winter/spring hunts would begin in December of the same calendar year that summer/fall hunts occur, and summer/fall hunts would begin in the next

calendar year following the end of a winter/spring hunt. The result is that there is a 1-month gap (November) between the end of a summer/fall hunt and the start of a winter/spring hunt, and then a 13-month gap between the end of a winter/spring hunt and the start of the next summer/fall hunt, and so on. Therefore, there would be up to five winter/spring hunts and five summer/fall hunts over the 10-year waiver period.

(2) It is evaluated (a) with and without low abundance thresholds for ENP gray whales, and (b) with a static low abundance threshold for the PCFG, below which hunting would cease. For our analysis, we have considered four potential scenarios: no low abundance threshold for the ENP stock, a threshold of 11,000 whales, a threshold of 16,000 whales, and a threshold of 18,000 whales. The thresholds are analyzed as Alternatives 7(a), 7(b), and 7(c), respectively. If an ENP abundance threshold is implemented and a cease-hunt were triggered by that threshold, hunting could resume once the ENP population abundance estimate increased above the selected threshold. All of the sub-alternatives include two low-abundance thresholds for the PCFG: hunting would cease if either (1) the most recent or forecasted abundance estimate for the PCFG fell below 192 whales, or (2) the most recent or forecasted minimum abundance estimate for the PCFG fell below 171 whales. If either of these thresholds are triggered, hunting would cease until the abundance and minimum abundance estimates for the PCFG increased above their respective thresholds.

Under Alternative 7, in order to conduct hunting and training activities in the winter/spring months, the Tribe would need to obtain requisite authorization for the potential incidental take of WNP gray whales (due to the chance of taking such a whale in winter/spring hunts). If they do not obtain an ITA for WNP gray whales, they would only be authorized to hunt and train in the summer/fall months. Also, if the Tribe were to obtain such authorization and subsequently struck a WNP gray whale during a winter/spring hunt (a highly unlikely event), then all hunting would cease unless and until additional hunt restrictions were imposed to prevent any additional WNP gray whale strikes. Such a restriction could include allowing only summer/fall hunts. For our analysis, we assume that the Tribe will either receive permits to hunt in all five winter/spring hunt seasons during the waiver period or that they will not receive permits for winter/spring hunts for the entirety of the 10-year waiver period, in which case only five summer/fall hunts would take place. It is, however, possible that the Tribe could receive permits for some of the winter/spring hunt years but not others. In this case, the impacts would be between those occurring if there were no winter/spring hunts and if there were five winter/spring hunts.

Under Alternative 7, the Tribe would utilize the same hunt area and overlap with the same winter/spring hunting seasons (i.e., all or portions of the December 1 through May 31 period) in alternating years. Like Alternatives 3 through 6, Alternative 7 also includes provisions to limit the number of struck and lost whales and measures to count struck and lost whales against the PCFG mortality limits. Alternative 7 also

incorporates a similar, but shorter, summer/fall hunting season in alternating years to that described under Alternative 4. This split-season hunt design was first proposed under Alternative 5 to limit the likelihood that tribal hunters would strike or otherwise harm a WNP gray whale during the winter/spring migration period. However, it has been modified under Alternative 7 to further limit potential impacts on WNP whales by restricting hunts to the summer/fall season every other year to avoid the WNP gray whale migration period. Finally, Alternative 7 incorporates the 10-year waiver period and shorter-duration permits that were proposed as additional precautionary measures under Alternative 6.

Table 4-1 summarizes the key hunting components associated with this alternative. Although these components have already been analyzed under Alternatives 2 through 6, to aid comparison we analyze them here in aggregate with the strike limits and other provisions described in Subsection 2.3.7, Alternative 7.

4.4.3.7.1 Change in Abundance and Viability of the ENP Gray Whale Stock

Like Alternatives 2 through 6, the potential direct and indirect mortality resulting from a whale hunt and hunt-related activities under Alternative 7 would be unlikely to change ENP gray whale stock abundance or viability compared to the No-action Alternative. As noted in Subsection 4.1.1.3, Potential Number of ENP and PCFG Whales Killed, the catch limit for the ENP gray whale stock set by the IWC would not change under this or any of the other alternatives; thus, the same number of ENP gray whales would likely be harvested over 6 years under Alternative 7 as under the No-action Alternative. If a Makah hunt for 12 whales over 6 years (2 harvested whales, on average, per year times 6 years) resulted in higher stress-related impacts than if those whales were harvested in a Chukotkan hunt under the No-action Alternative, the difference is unlikely to have an appreciable effect on the abundance and viability of the ENP gray whale stock as a whole. This is because the stress-related impacts associated with harvesting 12 whales over 6 years is likely to be minor in the context of the existing Chukotkan harvest level of 840 whales over 6 years.

If under the No-action Alternative the United States did not transfer unused portions of the catch limit to Russia, Alternative 7 would represent an increase in mortality of at most 5 gray whales over the 2 remaining years of the catch limit (2024 to 2025) (2.5 struck whales per year times 2 years) compared to the No-action Alternative. Because 5 whales are a tiny fraction of the overall ENP gray whale stock (0.03 percent), the increase in mortalities under Alternative 7 would be extremely unlikely to affect gray whale viability compared to the No-action Alternative.

If PCFG whales are uniquely adapted to exploit feeding areas in the southern portion of the ENP summer range, and that adaptation were lost if the PCFG were compromised, Alternative 7 has the potential to affect the long-term viability of the ENP stock as a whole. However, as described in Subsection 4.4.3.7.3, Change in Abundance and Viability of PCFG Whales, the best available

information indicates that the PCFG would still be viable with a hunt under Alternative 7, so there is no reason to believe that this alternative would have deleterious impacts on the ENP stock as a whole.

In order to determine the impacts of allowing hunting to continue until the ENP stock reaches a particular low abundance threshold on the viability of the ENP gray whale stock, we analyze the hunt in terms of the proportion of the population that would be impacted by strikes, unsuccessful strike attempts, and approaches at each threshold. The maximum number of whales that could be killed over the 10-year waiver period (25 whales) represents 0.2% of the low abundance threshold under Sub-Alternatives 7(a) and 7(b) and 0.1% of the threshold under Sub-alternative 7(c). The maximum number of whales that might be subjected to unsuccessful harpoon attempts and training throws (150 whales, assuming that each strike attempt is made on a different individual) represents 1.4% of the threshold under Sub-alternative 7(a), 0.9% of the threshold under Sub-alternative 7(b), and 0.8% of the threshold under Sub-alternative 7(c). Finally, the maximum number of whales that may be approached over the waiver period (3,530 whales, assuming that every approach is made on a different individual) represents 32.1% of the threshold under Sub-alternative 7(a), 22.1% of the threshold under Sub-alternative 7(b), and 19.6% of the threshold under Sub-alternative 7(c) (Table 4-15).

Table 4-15. Percent of the ENP gray whale stock that may be killed, subjected to unsuccessful harpoon attempts, or approached over the 10-year waiver period at each of three low abundance thresholds analyzed as Sub-alternatives.[14]

Abundance Estimate (N)	Percent of the Population Killed[a]	Percent of the Population Subjected to Unsuccessful Harpoon Attempts[b]	Percent of the Population Approached[c]
11,000	0.23	1.36	32.09
16,000	0.16	0.94	22.06
18,000	0.14	0.83	19.61

a. These percentages represent precautionary estimates as they assume that the Tribe would utilize all 25 strikes over the course of the 10-year waiver period and that all strikes would result in the death of the whale struck.
b. These percentages represent precautionary estimates as they assume that the Tribe would utilize all 150 allowable unsuccessful strike attempts and training harpoon throws over the course of the 10-year waiver period and that each attempt would be made on a different individual.
c. These percentages represent precautionary estimates as they assume that the Tribe would utilize all 3,530 allowable approaches over the course of the waiver period and that each approach would be made on a different individual.

[14] Based on the most recent abundance estimate of 14,526 (Eguchi et al. 2023a), Alternative 7 with no abundance threshold falls within the range considered in this table.

It is difficult to estimate the probability of any of these three thresholds being triggered. In the 55 years since systemic research monitoring of the ENP gray whale population began in 1967, the abundance estimate has fallen below these threshold levels 0, 9, and 14 times, respectively. Because the threshold for Sub-alternative 7(a) represents the lowest known abundance (approximately 11,000 whales in 1971-1972) from which the population has recovered, there are no empirical data to determine when or if the population dropped below that threshold prior to 1967. Prior to the current abundance estimate of 14,526, the last time the abundance estimate dropped below 16,000 whales was during the 1992/1993 survey season, after the stock experienced a severe decline from the 1987/1988 estimate of 26,916 whales. The ENP stock increased the following year to 20,944 whales. Prior to the abundance estimates in recent years (2022 and 2023), the last time the abundance estimate for the ENP gray whale stock dropped below 18,000 whales was in the 2007/2008 survey season when the abundance of the stock was estimated at 17,820. Once again, the stock rebounded the next year to 21,210 whales.

While we cannot assign a probability of being triggered to any of the three thresholds analyzed here, we can qualitatively determine that the threshold of Sub-alternative 7(a) is the least likely of the three to be triggered, while the threshold of Sub-alternative 7(c) is the most likely to be triggered. Once the threshold has been triggered, hunting would cease until the abundance estimate increased above the threshold once again. This could result in several years during the waiver period in which no hunting would be allowed. Therefore, it is possible that fewer whales may be killed under Sub-alternative 7(c) than under Sub-alternative 7(b), and that fewer whales may be killed under Sub-alternative 7(b) than under Sub-alternative 7(a). However, as highlighted in Table 4-15, the impacts to the population under all three of the thresholds are expected to be minimal.

Therefore, as with Alternatives 2 through 6, it is reasonable to conclude that Alternative 7 and each of its sub-alternatives are unlikely to have a measurable effect on the abundance and viability of the ENP gray whale stock as a whole. This conclusion is consistent with a recent analysis by the IWC Scientific Committee, which concluded that the hunt management plan met the conservation objectives of the IWC, including ensuring that ENP gray whales (including the PCFG component) would remain at or above the level resulting in the highest net recruitment (IWC 2018a).

4.4.3.7.2 Change in Abundance and Viability of the WNP Gray Whale Stock

Like Alternative 4, the timing of summer/fall hunts (July through October) under Alternative 7 is intended to completely avoid times when a WNP gray whale might be present in the hunt area. Available sighting data suggest that WNP whales could be encountered in the vicinity of the Makah U&A (Subsection 3.4.3.2.1, WNP Seasonal Distribution, Migration, and Movements) during much of the winter/spring hunting season under Alternative 7, perhaps with the exception of early May and late

December. During winter/spring hunts under Alternative 7, the probability of an individual encounter being a WNP gray whale is very remote (0.8% to 1.2%; Moore et al. 2023) and would be similar to other action alternatives allowing for springtime hunts (i.e., Alternatives 2, 3, 5, and 6).

There is limited data on how whales would react to unsuccessful harpoon attempts, but the reaction may be similar to that observed in whales that are tagged or biopsied (i.e., ranging from a subtle to overt response resulting in a potential temporary change in behavior). Based on these observations, it is likely that any changes in gray whale behavior due to unsuccessful strike attempts or training harpoon throws would be short-term in nature and would not have lasting effects on the behavior of targeted or nearby whales such that they would begin to avoid vessels.

Additionally, in contrast to all other action alternatives, Alternative 7 would impose a precautionary measure requiring hunting to cease if NMFS determines that a WNP gray whale had been struck. Therefore, Alternative 7 and its sub-alternatives are not expected to have a detectable impact on the abundance or viability of WNP whales. This conclusion is consistent with a recent analysis by the IWC Scientific Committee, which concluded that WNP gray whales would remain viable under the hunt management plan (Alternative 7, Composite alternative – Preferred), which meets the IWC's conservation objectives for WNP gray whales (in addition to ENP and PCFG whales) (IWC 2018a). Implementing a low abundance threshold for the ENP stock may further reduce the likelihood of encountering a WNP gray whales. Due to the relative likelihood of triggering the respective thresholds in Alternatives 7(a), 7(b), and 7(c), Sub-alternative 7(c) could result in the lowest relative risk to WNP gray whales, with Sub-alternative 7(a) posing the highest relative risk. This reduced risk would result from a reduction in the number of hunting years when the low abundance threshold was triggered during the waiver period.

4.4.3.7.3 Change in Abundance and Viability of PCFG Whales

During winter/spring hunts under Alternative 7, encounter rates and impacts on PCFG whales would be similar to those experienced under other springtime hunt Alternatives (2, 3, 5, and 6). During summer/fall hunts, impacts on PCFG whales would be similar to the summer/fall hunt under Alternative 4, except that female PCFG whales would be subject to harvest under Alternative 7. The average number of PCFG whales killed under Alternative 7 would be 1.4 whales per year (based on halving, given the alternating hunt seasons, the estimated 0.8 killed in winter/spring hunts and the maximum of 2.0 killed in summer/fall hunts; see Table 4-13), which is less than half the estimated PBR level of 3.5 whales per year (Carretta et al. 2023) and slightly more than one-tenth the number of whales estimated to recruit to the PCFG each year (10.4 whales; Harris et al. 2022). Given these

numbers, it is unlikely that the death of one to two whales per year would result in a detectable decrease in the abundance of the PCFG.

The overall impact on the viability of the PCFG from removing 1.4 PCFG whales per year under Alternative 7 would be intermediate to the other alternatives, i.e., lower than the approximately 2 whales under Alternatives 2 and 3, and slightly higher than the 0 to 1 whales under the No-action Alternative and Alternatives 4, 5, and 6 (see Table 4-14). The annual number of PCFG whales estimated to be approached (up to 142) would be the same as under Alternatives 2, 3, and 6 but higher than under the No-action Alternative and Alternatives 4 and 5; however, the impacts of these approaches are likely to be minor and temporary. In addition, under Alternative 7, the number of PCFG whales subjected to unsuccessful harpoon attempts (5-12) under Alternative 7 is similar to or lower than the under Alternatives 2 through 6. In contrast to the other action alternatives that rely on annual PCFG harvest or mortality limits, Alternative 7 would impose: (1) a mortality limit set at 16 PCFG whales over 10 years, no more than eight of which may be females; and (2) a stop-hunt trigger if the most recent or forecasted abundance estimate of the PCFG falls below 192 whales or the most recent or forecasted minimum abundance estimate falls below 171 whales. These safeguards—in addition to the small number of whales potentially killed relative to the informational PBR and the recruitment levels noted above—are expected to ensure the viability of the PCFG over time. This conclusion is consistent with a recent analysis by the IWC Scientific Committee which concluded that the PCFG of gray whales would remain viable under the hunt management plan specified by Alternative 7 (IWC 2018a). For the reasons discussed under Alternatives 2 through 6, available information indicates that gray whale distribution and habitat use under Alternative 7 would not change appreciably compared to the No-action Alternative.

It is possible that the impacts to the PCFG could be further reduced if the Tribe does not receive the requisite authorization to conduct one or more winter/spring hunts or if a low abundance threshold for the ENP stock is implemented and triggered during the waiver period, reducing the number of years during which hunting and hunt-related activities would be allowed to take place. Similar to the risk to WNP whales, due to the relative likelihood of triggering the respective thresholds in Alternatives 7(a), 7(b), and 7(c), Sub-alternative 7(c) could result in the lowest relative impact to PCFG gray whales, with Sub-alternative 7(a) posing the highest relative impact.

In 2019 the ENP population began experiencing a higher than normal level of strandings, leading NMFS to declare a UME for the stock (see Subsection 3.4.3.1.7, Strandings). As of October 2023, only two known PCFG animals have died during the current UME; however, it is not clear whether they were part of the UME (J. Calambokidis pers. comm., Cascade Research Collective, October 23, 2023).

Although the abundance estimate for the ENP stock demonstrated a 46% decline from the 2015/2016 to 2022/2023 abundance surveys, the PCFG abundance estimate has not experienced a proportional decline from pre-UME levels to 2020 (Harris et al. 2022). The abundance of the PCFG is considered to be stable.

4.4.3.7.4 Change in Numbers of Gray Whales Using the Makah U&A and OR-SVI Survey Areas

As noted in Subsection 3.4.3.4, Pacific Coast Feeding Group (PCFG) of Gray Whales, the most recent estimates of the number of whales that have been sighted in the Makah U&A and OR-SVI survey areas in two or more years are 119 and 199, respectively (Harris et al. 2022). During winter/spring hunts under Alternative 7, encounter rates and impacts on whales would be similar to those experienced under other spring-time hunt Alternatives (2, 3, 5 and 6). During summer/fall hunts, impacts on Makah U&A and OR-SVI whales would be similar to the summer/fall hunt under Alternative 4, except that female whales would be subject to harvest under Alternative 7. The average number of Makah U&A and OR-SVI whales killed under Alternative 7 would be 1.4 whales per year (based on the average of 0.8 whales in winter/spring hunts and 2 whales in summer/fall hunts for OR-SVI, and the average of 0.7 whales in winter/spring hunts and 2 whales in summer/fall hunts for the Makah U&A; see Table 4-13). For Makah U&A whales, this level of removal is 12-31% of the 6.5 new whales seen within the Makah U&A each year (Harris et al. 2022). For OR-SVI whales, this level of removal is 6-16% of the 12.7 new whales sighted in the OR-SVI each year (Harris et al. 2022). Given these percentages, and a likely level of annual recruitment into these areas (Subsection 3.4.3.4.1, PCFG Population Structure [PCFG Genetics and Recruitment]), it is uncertain whether the death of one to two whales per year would result in a detectable decrease in numbers of whale repeatedly sighted in the Makah U&A and OR-SVI survey areas.

The overall impact on the abundance from removing 1.4 Makah U&A or OR-SVI whales per year under Alternative 7 would be intermediate to the other alternatives (i.e., lower than the three to five whales under Alternatives 2, 3, 5 and 6, and slightly higher than the zero to one whales under the No-action Alternative and Alternative 4, respectively (see Table 4-14)). The annual number of Makah U&A and OR-SVI whales estimated to be approached (up to 142) would be higher than the other alternatives; however, the impacts of these approaches are likely to be minor and temporary. In addition, under Alternative 7, the annual number of Makah U&A and OR-SVI whales estimated to be subjected to unsuccessful harpoon attempts (4 to 12) are similar to or lower than the numbers analyzed for action Alternatives 2 through 6. Also, in contrast to the other action alternatives that rely on annual PCFG harvest or mortality limits, Alternative 7 would impose: (1) a mortality limit set at 16 PCFG whales over 10 years, no more than eight of which may be females; and (2) a stop-hunt trigger if the

most recent or forecasted abundance of the PCFG falls below 192 whales or the most recent or forecasted minimum abundance falls below 171 whales. A low abundance threshold for ENP gray whales could also reduce the number of years in which hunting and hunt-related activities could take place during the waiver period. These safeguards would also apply to Makah U&A and OR-SVI whales given that they belong to the PCFG.

In 2019, the ENP population began experiencing a UME (see Subsection 3.2.2, Strandings). As of October 2023, only two known PCFG animals have died during the current UME, and they had both been sighted previously in the Makah U&A and OR-SVI regions (Calambokidis et al. 2019; J. Calambokidis pers. comm., Cascade Research Collective, October 23, 2023). There is no evidence to suggest that the current UME is having a disproportionate impact on the PCFG (or whales in the Makah U&A and OR-SVI subareas) have occurred relative to the entire ENP stock.

Change in Numbers as a Result of Whales Being Killed

As described in Subsection 4.1.7, Alternative 7 and Table 4-13, the current maximum number of OR-SVI or Makah U&A whales killed would average 2.5 per year (3 in winter/spring hunt years and 2 in summer/fall hunt years). However, it is more likely that an average of 1.4 OR-SVI whales or 1.4 Makah U&A whales might actually be killed each year (and roughly 14 whales of each group over 10 years) given the presumed proportional presence of these whales in the proposed hunt area during the March through May time period when the Tribe is most likely to hunt during winter/spring hunt years and assuming the Tribe utilizes both strikes in summer/fall hunt years.

It is uncertain whether OR-SVI whales or Makah U&A whales killed under Alternative 7 would be replaced in the same year in which they were killed or in subsequent years because of the uncertainty regarding the recruitment mechanism and rate of recruitment into the PCFG and the uncertainty regarding the distribution of both PCFG and non-PCFG whales in these survey areas during the summer months. (As described above in Subsection 4.4.2.4, Change in Numbers of Gray Whales in the Makah U&A and OR-SVI Areas, whales in these survey areas during the summer months include both whales that have visited the PCFG area in more than 2 years [PCFG whales] and whales that visit only once and are never sighted again [transient, non-PCFG whales]). Harris et al. (2022) have analyzed the most recent sighting data for PCFG whales. From 1996 through 2020 there have been 645 uniquely identified whales sighted in the OR-SVI area from June through November. An average of 112 whales are sighted each year, and of these, an average of 24 whales are newly seen each year (ranging from 8 to 56 whales, and 11 whales for 2020). The annual average number of whales newly seen and then seen again in a subsequent year ("returning" whales) in the OR-SVI area for 1996 to 2019 is 13 whales (ranging from 3 to 37 whales, and 10 whales for 2019, the most recent year reported). In the Makah

U&A, 356 uniquely identified whales have been sighted from 1996 through 2020 in the June through November time period. An average of 33 whales are sighted each year, and of these, an average of 14 whales are newly seen each year (ranging from 1 to 29 whales, and 18 whales for 2020). The annual average number of whales newly seen and then seen again in a subsequent year for 1996 to 2019 is 7 whales (ranging from 2 to 18 whales, and 11 whales for 2019, the most recent year reported). These sighting data, while subject to the survey limitations described in Subsection 4.4.3.7.3, Change in Abundance and Viability of PCFG Whales, demonstrate that many new whales are seen each year in these OR-SVI and Makah U&A areas, and of these whales, variable but large numbers are seen (or never seen) again.

Based on the annual average number of newly seen whales in the Makah U&A and OR-SVI survey areas (14 and 24 whales, respectively), it is possible that if an average of 1.4 Makah U&A or OR-SVI whales were removed under Alternative 7, they would be replaced during that year with new Makah U&A or OR-SVI whales. In that case, Alternative 7 would not result in a decrease in the total number of gray whales using the Makah U&A and OR-SVI survey areas during a given summer feeding period, compared to the No-action Alternative.

Over time, an ongoing hunt could reduce the abundance of PCFG whales and thereby reduce the number of whales using the Makah U&A and OR-SVI areas. The extent to which a hunt would reduce abundance over time would depend on the rate at which external recruits would replace killed whales, similar to the discussion above for change in numbers of PCFG whales (Subsection 4.4.3.7.3, Change in Abundance and Viability of PCFG Whales). It seems likely that if the killed Makah U&A or OR-SVI whales were returning whales, they would be replaced in subsequent years with another returning whale, based on the average number of newly seen whales in the Makah U&A and OR-SVI survey areas that are then seen again in a subsequent year (7 and 13 whales, respectively). It is also possible that the removal of PCFG whales would result in the presence of more non-PCFG whales using the Makah U&A and OR-SVI during the summer months (i.e., whales that appear in the area in only one year and do not return again). This is uncertain, however, so the analysis does not assume it would occur.

Change in Numbers as a Result of Change in Distribution of Feeding Whales

Alternative 7 limits the number of approaches for PCFG whales to 142 per year. In estimating the maximum potential impact to feeding whales, we assume that the Tribe will utilize all allowable approaches and that each approach will be taken on a unique individual. Therefore, the estimated number of PCFG, OR-SVI and MUA whales that may be approached annually under Alternative 7 is up to 142 whales. This is a precautionary estimate as it is unlikely that these assumptions will be met. It

is unknown whether this level of disturbance would cause whales to change their distribution (i.e., avoid the hunt area), although evidence suggests that any changes would be temporary and minor (see Subsection 3.4.3.6.6, Vessel Interactions).

Some aspects of approaches by Makah whale-hunting canoes would cause a disturbance similar to that observed from approaches of motorized whale-watching vessels or vessels used for photo identification work. It is known that when approached by vessels some gray whales exhibit temporary behavioral responses, such as changing course, swimming speed, and respiratory patterns (Subsection 3.4.3.6.6, Vessel Interactions). However, there is no evidence that gray whales have altered their distribution or habitat use in lagoons in their winter range in response to the presence of whale-watching vessels. While some researchers have suggested that gray whales may have altered their migration distance from shore in response to vessels and other human activity, other researchers concluded there is no evidence suggesting such a relationship (see Subsection 3.4.3.6.6, Vessel Interactions). Thus, whale response to approaches is likely to be temporary (minutes or hours).

It is less certain whether the intensity of unsuccessful harpoon attempts would result in more than a temporary disturbance of Makah U&A or OR-SVI whales and cause them to avoid portions of the Makah U&A or OR-SVI either for a short period (days to weeks) or a longer period (for example, over a period of years). As described in Subsection 3.4.3.3.2, ENP Seasonal Distribution, Migration, and Movements, the availability of prey may be the factor most strongly affecting gray whale numbers in particular feeding areas. If prey is available in the Makah U&A or OR-SVI, hunting by the Makah Tribe might not result in either a short- or long-term response from summer-feeding whales. Many new whales are seen in the Makah U&A and OR-SVI every year, and there is significant interchange with whales from other adjacent areas in the PCFG range (Subsection 3.4.3.4.3, PCFG Abundance and Trends). Thus, even if some whales do abandon the area as a result of hunting disturbance, new whales that had not previously been exposed to hunting might come into the area. The example of gray whales hunted by Chukotka Natives may be instructive in trying to predict whether there would be a change in gray whale use of the Makah U&A and OR-SVI survey areas. Scores of whales have been hunted and killed by Chukotka Natives over several years (Table 3-52), yet whales continue to be available for harvest, suggesting that hunt-related activities have not resulted in major changes in gray whale numbers, distribution, or habitat use in that area.

Spatially, the OR-SVI area is a relatively small part (approximately 11 percent) of the entire PCFG range, but the area attracts a disproportionately high percentage (approximately 71 percent; Calambokidis et al. 2019) of PCFG whales sighted in a given year. Also, PCFG whales exhibit extensive movements during a given year or from year to year, presumably searching for prey

(Subsection 3.4.3.1.4, Feeding Ecology and Role in the Marine Ecosystem, and Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). For example, Calambokidis et al. (2014) and (2019) estimated that over 60 percent of PCFG whales that had been sighted on 6 or more days were seen somewhere in the OR-SVI area and across a latitudinal range of greater than 30 nautical miles (i.e., roughly equivalent to the coastal portion of the Makah U&A) (Subsection 3.4.3.4.2, PCFG Seasonal Distribution, Migration, and Movements). Therefore, it is reasonable to expect that other PCFG whales could move in and take the place of whales that leave the Makah U&A or OR-SVI areas in response to hunting. For example, PCFG whales feeding outside the OR-SVI survey areas (e.g., whales from west Vancouver Island) could take the place of whales removed from the OR-SVI, and PCFG whales feeding outside the Makah U&A (e.g., from southern Vancouver Island) could take the place of whales removed from the Makah U&A. In addition, if there are other feeding areas that are not subject to hunting disturbance, the whales can and may easily move to those other areas. Over time and with ongoing hunt-related disturbance, fewer whales might use the hunt area (which is just one portion of the Makah U&A and OR-SVI areas), but such abandonment might be offset to some extent by new whales that recruit to the PCFG and have not been exposed to such disturbance.

Change in Numbers - Summary

Compared to the No-action Alternative in which no Makah U&A or OR-SVI whales are likely to be killed by hunting, Alternative 7 represents a potential decrease in the number of whales using these survey areas during the summer period (especially if external recruits do not replace killed whales). The number of whales approached (142) under Alternative 7 would be higher than any other action alternative. The number of OR-SVI and Makah U&A whales subjected to harpoon attempts (8.3 and 8.1, respectively, on average) under Alternative 7 would be higher than under Alternatives 4, 5, and 6 but lower than under Alternatives 2 and 3. As with Alternatives 2 through 6, it is most likely that gray whales would continue using these survey areas during the summer months because (1) under Alternative 7, PCFG mortality limits and low abundance thresholds have been set as a precautionary measure to protect the population, and the IWC analysis shows that PCFG whales would remain viable with a Makah hunt; (2) PCFG whales are dense and abundant in the OR-SVI area; (3) PCFG whales are highly mobile within the PCFG range; (4) there are many new and returning whales available to replace killed whales; and (5) gray whales continue to return in large numbers to feeding areas where scores are actively hunted and killed each year (i.e., waters around Chukotka), suggesting that hunting will not cause them to abandon the PCFG feeding area.

4.4.3.7.5 Welfare of Individual Whales

As discussed in Subsection 4.1.1.3, Potential Number of ENP and PCFG Whales Killed, the number of gray whales that might be harvested from the ENP stock under all alternatives, including Alternative 7 and the No-action Alternative, would not change. It would remain at the existing IWC catch limit of 980 whales in a 7-year period, and no more than 140 whales in any one year. The difference is that under the No-action Alternative, the entire catch could be taken by Chukotka Natives, while under Alternative 7 the Makah Tribe could kill up to 17 whales over the 7-year period from the 980 whale catch limit.

A major difference between Alternative 7 and the No-action Alternative is in the number of gray whales that might be disturbed via vessel approaches and unsuccessful harpoon attempts. Under Alternative 7, it is possible that 353 gray whales might be approached per year, and an average of 15 of those whales subjected to unsuccessful harpoon attempts (Subsection 4.1.7, Alternative 7) (Table 4-13). (The number of whales approached does not include the number that might be approached by vessels other than those used by Makah hunters). Some of the whales approached could be subsequently encountered during a hunt by Chukotkan Natives (which would typically occur during the summer and fall months), so there is a greater potential for increased disturbance under Alternative 7 compared to the No-action Alternative. However, this increased risk is extremely low; the high ENP abundance reduces the likelihood that an individual whale will encounter both Makah and Chukotkan hunters. In addition, an unsuccessful harpoon attempt— the most severe form of disturbance aside from struck and lost whales—would still be limited to an average of 15 whales per year over 10 years, which is a very small fraction (0.1 percent) of the entire ENP stock.

The proportion of whales struck and lost could be greater in a Makah hunt under Alternative 7 than a Chukotka Native hunt under the No-action Alternative because the Chukotka Natives have more recent hunting experience. In recent years, the Chukotka Natives report that one percent of the whales struck in their hunt are lost. It is not possible to predict the proportion of whales that would be struck and lost in a Makah hunt under Alternative 7. The proportion of whales struck and lost under Alternative 7 in winter/spring hunts could also be greater than the proportion in a Chukotka Native hunt because seasonal restrictions on the Makah hunt in those years could result in hunts occurring in rough weather and sea conditions. Hunting under unfavorable conditions could reduce the accuracy of the hunters and make it more difficult to successfully land a killed whale (thus increasing the proportion of whales struck and lost).

Whales killed with a rifle in a Makah hunt under Alternative 7 could experience a shorter time to death than whales killed with a rifle in a Chukotka Native hunt because of the requirements proposed by the

Makah (such as minimum visibility) and because the Makah would use a higher caliber killing weapon than the Chukotka Natives use. Whales killed with an explosive grenade(s) in either hunt would likely experience a similar time to death. Thus, compared to the No-action Alternative, Alternative 7 could result in the same or shorter time to death, depending on the weapon used.

4.5 Other Wildlife

4.5.1 Introduction

This subsection addresses the potential for the six alternatives to affect wildlife species in the action area. Species analyzed in this subsection include marine mammals (other than gray whales) (refer to Subsection 4.4, Gray Whale), birds, and reptiles (i.e., sea turtles). Analyses in this subsection address all species identified in Subsection 3.5, Other Wildlife Species, that occur in the action area, including those listed as threatened or endangered under the ESA. These analyses focus on wildlife species that may occur in the action area and that have potential to be affected by hunt-related activities. For species that are not likely to occur near proposed hunt activities, no effects would be expected.

There are three primary sources of potential effects of whale-hunt-related activities on wildlife. First are the potential direct effects related to visual and noise disturbance from anticipated concentrations of aircraft and boat traffic, and the use of guns and explosives associated with any hunt. Such disturbance may disrupt the behavior of individuals or groups of animals in the action area. Second are the potential indirect effects from visual and noise disturbance that may disrupt prey distribution or abundance, resulting in decreased foraging efficiency. Third is the potential for direct harm to marine mammals (other than gray whales) from increased vessel traffic and hunt-related activities that could cause injury or death if a marine mammal were struck by a vessel or a projectile associated with a hunt. The following subsections discuss these issues in greater detail.

4.5.2 Evaluation Criteria

We used three evaluation criteria to assess the potential direct and indirect effects of the alternatives on other wildlife species in the action area: (1) potential changes in behavior because of disturbance (visual and noise), (2) potential changes in prey availability, and (3) potential for physical injury (e.g., from ship strikes or weapons).

The following subsections describe the potential for the alternatives to affect wildlife in the action area. For each alternative, the discussion addresses potential disturbance and injury and, where relevant, potential changes in prey availability. For each criterion, potential effects on marine mammals (excluding gray whales) are described first, followed by birds and reptiles (turtles). For each species group, ESA-listed endangered and threatened species are addressed first, followed by those species that

are not listed. Non-listed seabirds and other birds that use coastal habitats are analyzed by habitat association, described under Subsection 3.5.3.2.2, Non-listed Birds and Their Associated Habitats. That subsection reviews the habitat types and discusses which species of birds are included in each zone. To reduce repetition, species that would probably be affected similarly under a particular evaluation criterion are addressed together.

4.5.2.1 Disturbance

Subsection 4.11, Noise, describes the sources and level of noise-related disturbance that may occur during a hunt. Subsection 3.5.3.3, Sensitivity of Wildlife to Noise and Other Disturbance, describes how wildlife species typically respond to these types and sources of noise. Many activities associated with a whale hunt would have the potential to generate noise levels that would exceed ambient levels in parts of the action area (Subsection 4.11.2.1, Noise Generated by Hunt-related Activities). Under current conditions (the No-action Alternative), noise from vehicles, marine vessels, and aircraft is commonly heard throughout the Makah U&A. Other sources of noise include commercial areas, sports fields, logging operations, and the foghorn at Tatoosh Island. Natural sounds, such as those of wind and surf, contribute to high ambient noise levels in portions of the action area, particularly in areas close to the shoreline of the Pacific coast and the Strait of Juan de Fuca. A whale hunt and associated monitoring, protests, and law enforcement would be expected to result in increased noise and human activity levels relative to levels under the No-action Alternative. In addition, firearms and other explosive devices used to strike and kill a whale would produce high-intensity, short-duration noise.

Sources of noise and visual disturbance associated with whale hunt activities may include aircraft overflights (both fixed wing and helicopter), boat traffic (including both motorized and non-motorized craft), gunfire, and explosives. Anthropogenic noise can be either transient or continuous and can result in a variety of effects on wildlife with consequences ranging from none to severe (Würsig and Richardson 2002; Kunc and Schmidt 2019). Examples of transient noise associated with whale-hunting under the action alternatives could include helicopters, planes, and explosions; examples of continuous noise include vessels underway. The amount of noise generated by vessels and aircraft under each alternative would depend on the number of days of scouting or hunting that are likely to occur and whether media or other observation vessels or aircraft are present. The amount of noise produced by weapons would depend on the number of whales that may be struck and killed under a given alternative.

Among the proposed alternatives, the No-action Alternative would pose the lowest risk of disturbance to other species of wildlife. Under all of the action alternatives, the greatest potential for direct effects on other wildlife species would be from noise and visual disturbance related to increased human

activity directly and indirectly associated with a whale hunt. This analysis considers the likelihood of effects on wildlife as a result of such increased disturbance.

Analyses in this subsection consider the nature and magnitude of hunt-related activities in relation to wildlife occurrence and behavior (e.g., nesting, migration, foraging, nursing, and other critical survival activities). For each species, species group, or habitat type, the analyses examine the proximity of hunt-related activities to sensitive areas (e.g., rookeries, nest sites, haulout sites). Alterations in wildlife behavior may occur if vessels or aircraft associated with hunt-related activities travel close enough to sensitive areas to disturb animals (Subsection 3.5.3.3.2, Boat Traffic, and Subsection 3.4.3.6.6, Vessel Interactions).

It is possible that the number and types of vessels and aircraft that would participate in each hunting expedition (including observation, protests, law enforcement, and media coverage) would vary among the action alternatives. For example, hunting during summer (i.e., under Alternative 4) could result in a greater number of observers overall because of an increased likelihood of more hunting occurring during periods of good weather. Conversely, alternatives that allow more hunts might attract less public interest and less media coverage over time. Because of the difficulty of predicting such variations and how they might affect the precise numbers of vessels and aircraft participating in each hunt, this analysis assumes that each hunting expedition would be accompanied by the same amount of vessel and aircraft activity and associated disturbance, and that vessels and aircraft associated with each hunt would be similar to those associated with the previous hunts, as described in Subsection 3.11.3.2.1, Atmospheric Noise. It is not possible to predict the specific location of hunt-related activity on a given day under any action alternative. The area in which hunting would be allowed would be the same among all of the action alternatives except Alternative 3, under which Makah hunters would be prohibited from making an initial strike on a gray whale within 5 miles (8 km) of shore.

4.5.2.1.1 Marine Mammals (Excluding Gray Whales)

As described in detail in Subsection 3.5.3.3, Sensitivity of Wildlife to Noise and Other Disturbance, marine mammals in the coastal environment (e.g., seals, sea lions, and sea otters) may react to changes in noise and human presence by altering behaviors such as breeding, nursing, grooming, foraging, or resting. The effects of such disturbance on marine mammals would be related primarily to the type, level, timing, and location of disturbance relative to species locations and activity. Animals might be disturbed at haulout sites and spend more time in the water, thereby reducing rest periods, altering nursing frequency, and modifying thermoregulation. Species that breed in the action area (i.e., harbor seals and sea otters) could be disturbed during the summer when hunt activities might disrupt pupping or breeding activities or interrupt the female/pup bond during nursing.

Whales, dolphins, and porpoises might react to increased disturbance related to a hunt by changing their swim speed and/or direction or increasing dive duration. The sight and sound of vessels might also disturb the foraging behavior of seals and sea lions in the water and may affect foraging and grooming behaviors of sea otters. Noise from vessels, aircraft, and weapons associated with whale hunting might disrupt the ability of predatory species (e.g., killer whales) to communicate and to locate or obtain prey. For all of these species of marine mammals, any resultant effects would likely be temporary (lasting a few minutes to a few hours) and localized (occurring near the hunt), therefore impacting a small proportion of the population. For more information on the current abundance and associated population parameters (including PBR) for each of these species, refer to Section 3.5, Other Wildlife.

Subsection 4.11.2.1, Noise Generated by Hunt-related Activities, discusses the level and duration of noise anticipated from weapon use and vessel and aircraft activity associated with hunting. It is not possible to predict in advance the exact level of atmospheric or underwater noise that vessels and aircraft would produce on a typical day of hunting. Depending on the method used to kill a struck whale, the loudest noise levels associated with hunting would be from gunshots (atmospheric noise) or grenade explosions (underwater noise) (Subsection 4.11.2.1, Noise Generated by Hunt-related Activities). Noise from a gunshot would probably decay to ambient levels within 1 or 2 miles of the source (although this distance cannot be determined with certainty), while a grenade explosion underwater might not decay to ambient levels for several miles. Noise from these sources would last only a few seconds.

Overall, the number of marine mammals that would potentially occur close enough to hunting activities to be affected by the associated noise would probably be low. As presented in Table 3-16, frequency of occurrence of about half of the federal- and state-listed[15] species of marine mammals in the action area is uncommon or rare. Nearly all of the species of marine mammals that may occur in the action area, including ESA-listed species, are wide-ranging and may travel long distances as part of their normal daily movements. Sea otters do not typically travel long distances on a daily basis but are known to travel extensively in the vicinity of the Makah U&A (Lance et al. 2004; Hale et al. 2022). Thus, any changes in behavior of these species because of disturbance from whale-hunt-related activities would likely be temporary and would probably not have lasting effects on individuals or populations. Noise effects specific to particular species and species groups of wildlife are discussed below.

[15] Species listed as endangered under Washington State law can be found at WAC 220-610-010.

ESA-listed Marine Mammals

Several ESA-listed species of wildlife are known to occur in the action area but are not likely to be affected by the proposed whale-hunt-related activities because of their rare to uncommon occurrence along the Washington coast and/or their use of habitats too far from shore to encounter any hunt-related activities in the action area (Table 3-16). These species include five ESA-listed species of whales (sperm, blue, sei, fin, and right). When present in Washington waters, all of these whale species typically occur in pelagic deep waters offshore in the Makah U&A beyond the bounds of where proposed hunting would likely occur under any action alternative. There may be brief periods during hunt-related activities, particularly as a result of aircraft activities or grenade explosions, when ESA-listed marine mammals would be exposed to increased noise levels and might modify their behavior (e.g., dive duration, swim direction, etc.) in response. Although ESA-listed species of marine mammals have a low likelihood of encountering hunt-related activities, the species that would have the highest likelihood of encountering these activities include the Southern Resident killer whale and Mexico and Central America DPS humpback whale. These species are discussed in further detail below.

As mentioned above, all species of marine mammals, with the exception of sea otters, that may occur in the action area, including ESA-listed species, are wide-ranging and may travel long distances as part of their normal daily movements. Any changes in behavior of these species because of whale-hunt-related disturbance would likely be temporary and are not anticipated to have lasting effects (NMFS 2023a).

Killer Whale

Offshore, transient, Northern Resident, and Southern Resident killer whales might occur in or near the action area year-round. Of these, Southern Resident killer whales are the only DPS listed under the ESA. The majority of Southern Resident sightings have occurred in the summer months in inland waters of Washington and Southern British Columbia, however both Northern and Southern Residents have been recorded in the Strait of Juan de Fuca and off the coast of Washington in the vicinity of the Makah U&A (Hanson et al. 2013; Emmons et al. 2021). Therefore, the potential exists for killer whales to be in the vicinity of a whale hunt and thus be disturbed by the associated activities under any of the action alternatives.

As with other species of marine mammals, noise and human activity related to the use of vessels associated with whale hunting might cause killer whales to modify their behavior. As discussed in Subsection 3.5.3.1.1, ESA-listed Marine Mammal Species, listing factors for the killer whale included, among other things, noise and disturbance from vessel traffic. Killer whales may temporarily change dive duration or swim direction, for example, in response to hunt-related disturbance. Disturbance from vessels, aircraft, and weapons associated with whale hunting also has the potential to disrupt the ability

of killer whales to communicate or find prey. Any resultant changes in behavior would be temporary, likely lasting only as long as a hunt was underway. As with other species of marine mammals that may occur in the action area, killer whales are wide-ranging and may travel long distances as part of their normal daily movements. While hunting activities were underway under any of the action alternatives, killer whales would likely be able to move to areas where no disturbance would occur.

As discussed in Subsection 3.5.3.1.1, ESA-listed Marine Mammal Species, the primary constituent elements for the Southern Resident killer whale critical habitat include (1) water quality to support growth and development; (2) prey species of sufficient quantity, quality, and availability to support individual growth, reproduction, and development, as well as overall population growth; and (3) passage conditions to allow for migration, resting, and foraging. None of the proposed alternatives would appreciably affect these elements of critical habitat for this species.

Humpback Whale

Humpback whales occur occasionally in or near the action area and might occur in the vicinity of a gray whale hunt. Although non-listed Hawaii DPS humpback whales are the most common DPS present in the action area, individuals from two ESA-listed DPSs—Central America and Mexico—may be present when hunt activities occur. Humpback whales are also visually distinguishable from gray whales and are therefore not likely to be inadvertently pursued by Makah hunters. Noise and visual disturbance from vessels, aircraft, or weapons could affect humpback whales above or below the water. Potential effects would include changed swim speed or direction or increased dive duration to avoid the noise.

As mentioned above, all species of marine mammals that may occur in the action area, including humpback whales, are wide-ranging and may travel long distances as part of their normal daily movements. Thus, any changes in behavior (e.g., migration, movements, and habitat use) of these species because of whale-hunt-related activities would likely be temporary and would probably not have lasting effects.

Non-ESA-listed Cetaceans

Of the 14 non-listed species of cetaceans discussed in Subsection 3.5.3.1, Marine Mammals, nine are rare or uncommon off the Washington coast and/or use habitats in the pelagic environment, far from the vicinity of whale-hunting activities in the action area (Table 3-16). Thus, these nine species are highly unlikely to be affected by whale-hunt-related activities and are not considered further in this analysis. These nine species include the common dolphin, striped dolphin, false killer whale, pilot whale, pygmy sperm whale, minke whale, Baird's beaked whale, Curvier beaked whale, and

Stejneger's beaked whale. More frequent visitors to the coastal environment where a hunt is likely to occur include the non-listed DPSs of killer whales and humpback whales discussed above, as well as harbor porpoises, Dall's porpoises, northern right-whale dolphins, Risso's dolphins, and Pacific white-sided dolphins. When any of these species are present in coastal areas during a hunt, they would probably be affected by disturbance from vessels, aircraft, or weapons associated with a whale hunt. Whales, dolphins, and porpoises might react to hunt-related disturbance by changing their swim speed or direction or increasing dive duration. Noise from vessels, aircraft, and weapons associated with whale hunting might disrupt the ability of predatory species (e.g., killer whales) to communicate and to locate or obtain prey.

As mentioned above, all species of marine mammals that may occur in the action area, including the non-ESA-listed species of cetaceans, are wide-ranging and may travel long distances as part of their normal daily movements. Any changes in behavior of these species because of whale-hunt-related activities would likely be temporary and is not anticipated to have lasting effects.

Non-ESA-listed Pinnipeds

As discussed in Subsection 3.5.3.1, Marine Mammals, six non-ESA-listed species of pinnipeds are known to occur in the action area: harbor seal, Steller sea lion, California sea lion, northern elephant seal, and northern fur seal. Of these species, only the Steller and California sea lions and harbor seals have a reasonable potential to occur in the vicinity of a hunt in the action area (Subsection 3.5.3.1.2, Common Species off the Washington Coast). Northern fur seals and northern elephant seals occur infrequently and in relatively low abundance in the action area, or they occur in the pelagic environment where they would probably not encounter whale-hunt-related activities.

Steller sea lions, California sea lions, and harbor seals are, however, common in the action area. All three species use offshore islands and rocks as haulout sites for resting (Steller and California sea lions) or to nurse pups (harbor seals). Most offshore islands and rocks in the action area are less than 1 mile (1.6 km) from the shoreline, where hunt activities are expected to occur under all action alternatives except for Alternative 3, Offshore Hunt. Impacts to pinnipeds can be minimized or avoided altogether by maintaining buffer zones around haulout sites, as recommended by the MMPA marine viewing guidelines (available at https://www.fisheries.noaa.gov/insight/viewing-marine-life) and Olympic Coast National Marine Sanctuary. These locations can be identified by sanctuary staff during the National Marine Sanctuary Act consultation process in the permitting phase of the hunt. . Thus, these species' haulout sites would have a very low likelihood of being affected by hunt-related activities, although the noise associated with helicopters and gunshots in particular, would carry much farther than the immediate hunt area. Disturbance associated with the use of hunt-related vessels might

occasionally disrupt pinniped foraging behavior in the action area. As with other species of marine mammals that may occur in the action area, these pinnipeds are wide-ranging and may travel long distances as part of their normal daily movements. Because pinnipeds rarely forage in large groups and only a minute proportion of the action area would be affected by whale hunting activities at any given time, the number of these animals that could be affected by hunt-related disturbance during a whale hunt would likely be extremely small. In addition, any associated changes in behavior would be temporary, likely lasting only as long as a hunt was underway. Most portions of the action area do not receive high levels of vessel traffic. Under any of the action alternatives, while hunting activities were underway, seals and sea lions would likely be able to find foraging opportunities in areas where no disturbance would occur. Any changes in behavior because of whale-hunt-related disturbance would likely be localized and temporary and would probably not have lasting effects. Overall, the effects of the alternatives on hauled out or foraging Steller sea lions, California sea lions, and harbor seals would likely be negligible.

Northern Sea Otter

Northern sea otters are common in the area throughout the year and can travel extensively or shift their distribution seasonally to forage or seek more sheltered waters (Lance et al. 2004). They generally inhabit shallow coastal waters less than 1 mile (1.6 km) from shore, but they may occasionally be seen as far as 3 miles (4.8 km) off shore. Disturbance from the use of vessels, aircraft, or weapons associated with whale hunting might affect sea otters that are swimming, foraging, or grooming by causing them to spend time avoiding the activity and thereby reducing rest and grooming periods. Hunt-related activity and noise could also disrupt activities related to breeding, such as nursing or caring for young. Based on the low density of northern sea otters in the action area, the number of animals that could be affected by hunt-related disturbance during a whale hunt would likely be small. In addition, any associated changes in behavior would be temporary, likely lasting only as long as a hunt was underway. For these reasons, the effects of whale hunting on northern sea otters would likely be minor.

4.5.2.1.2 Other Marine Wildlife

ESA-Listed Species

Several ESA-listed species of wildlife are known to occur in the action area, including two ESA-listed species of birds (short-tailed albatross and marbled murrelet) and four species of sea turtles (leatherback, green, loggerhead, and olive ridley). Although the bald eagle was recently delisted, the species is still protected under the Bald and Golden Eagle Protection Act and is thus addressed with the ESA-listed species below.

Short-tailed Albatross

When present in Washington waters, short-tailed albatrosses occur in pelagic, deep waters off shore in the Makah U&A beyond the area where proposed hunting would likely occur under any action alternative. However, their presence in Washington is very rare. There may be brief periods during hunt-related activities, particularly as a result of aircraft activities or grenade explosions (if grenades are used), when a short-tailed albatross could be exposed to increased noise levels (compared to the No-action Alternative) and might modify its behavior in response, but the likelihood of such an encounter would be extremely low due to the rarity of their occurrence in the project area. As is the case for most marine wildlife in the action area, short-tailed albatrosses are wide-ranging and may travel long distances as part of their normal daily movements. In the extremely unlikely event that exposure were to occur, any changes in behavior of these species because of whale-hunt-related disturbance would likely be temporary and localized.

Marbled Murrelet

Murrelets either dive or paddle away when approached by a boat, depending on the speed of the boat. If disturbance occurs in a foraging area where murrelets congregate, the birds potentially could lose an opportunity to find a fish. It is unknown how murrelets react to gunfire, helicopters, and other loud disturbances to which these birds are unaccustomed, although helicopters and gunfire would probably cause them to either dive or fly away from the area completely (Nelson 1997). Flushing birds might stress their energy reserves, given that they have to fly long distances to bring fish to their young during the breeding season (April 1 through September 15). The time of day that the disturbance occurred might also make a difference in the degree of impacts on this species. During the breeding season, most foraging takes place during the early morning hours (Nelson 1997).

Whale hunts and associated activities under the action alternatives could disturb adult murrelets foraging at sea, potentially reducing the amount of prey brought to chicks. The likelihood of any disturbance is low, however, because hunt-related activities would occupy a small proportion of the action area at any given time. Marbled murrelets would likely be able to find foraging opportunities in areas where no disturbance would occur, although this could be more difficult for birds undergoing a 2-month molt (which occurs during the latter half of the year).

Bald Eagle

As mentioned above, although bald eagles have been removed from the ESA list of threatened species, they are given particular consideration in this analysis based on the regulatory protection afforded by the Bald and Golden Eagle Protection Act. Bald eagles are present in the action area throughout the year, and they nest, roost, and forage along the coastline. Bald eagles are known to flush off nests and

roost sites when people or vessels get too close, and they may be deterred from foraging in an area where many vessels congregate on the water (Stinson et al. 2001). Bald eagles are more sensitive to disturbance during the spring months when they nest. Flushing off their nests, particularly at the beginning of the breeding season, might affect the physical condition of birds or cause them to abandon a nest, which could in turn affect the ability to feed chicks. Once chicks hatch in May, there would be less likelihood of nest abandonment.

Helicopters, fixed-wing aircraft, and increased human activity associated with hunt-related activities would probably alter the behavior of bald eagles that may be present in the area during a hunt. Bald eagles flush away from nesting or foraging sites when approached by helicopters as close as 0.4 mile (0.64 km). Flushing distances are greater in the breeding season than in winter. While eagles would flush when helicopters come within 1,000 feet (304.8 m) in the winter, they would flush if helicopters would approach to within 1,500 feet (457.2 m) when on a nest (Stalmaster and Kaiser 1997). It is likely that some eagles that cannot tolerate human presence and its associated noise within a particular distance of their feeding or nesting activities may flush away from nesting and foraging sites.

Sea Turtles

Four species of ESA-listed sea turtles occasionally occur along the Washington coast: leatherback, green, loggerhead, and olive ridley. Leatherback sea turtles are seldom seen in the action area, but they may migrate along the Washington coast during non-breeding years; thus, they could be found in the action area at any time. This species occasionally forages in the deep pelagic waters off the Washington coast. Rarely, leatherbacks appear in bays and estuaries, although such locations are not their preferred habitat. Green, loggerhead, and olive ridley sea turtles are found in warmer waters and only approach the Washington coast in El Niño years. All four of these species of turtles would most likely continue to forage along the Washington coast under the action alternatives, especially during warm winter years. These species of turtles are not easily disturbed during foraging activities; if approached by boats, they would most likely move slowly away from any sources of disturbance. Some short-term effects related to temporary disturbance from hunt-related activities could cause some turtles to move away from a preferred feeding area, but this would probably be temporary. As discussed in Subsection 4.3.3.2.1, Pelagic Environment, any disturbance of animals in pelagic waters would be minor (vessels are small and the area is large and highly energetic), local (limited to waters near the activity), and of short duration (minutes to hours). Based on the low likelihood of sea turtles occurring in the vicinity of hunt-related activities, as well as the minor consequences of any disturbance, none of the alternatives would be expected to result in appreciable disturbance-related effects on sea turtles. Because none of

these species of turtles nests in Washington State, there would be no expected impacts from whale-hunt-related activities on the nests or nesting habitat of sea turtles.

Non-Listed Marine Birds and Their Associated Habitat

The action area includes some of the largest seabird colonies in the continental United States, with more than 100 species of birds using this area for nesting, wintering, or foraging. Analyses in this subsection focus on the six types of habitat these species use and the effects that the alternatives would have on these habitat types (i.e., beaches, bays, and estuaries; coastal headlands and islands; nearshore marine habitat; inland marine habitat; marine shelf habitat; and oceanic habitat). All six habitat types are present in the action area and are discussed individually as appropriate.

Beaches, Bays, and Estuaries

The beaches, bays, and estuaries along the Olympic coast support large numbers of marine and shorebirds for both breeding and foraging, particularly during migration. These habitat types support the highest numbers of species compared with other habitat types. Disturbance from vessels and aircraft that pass near beaches, bays, and estuaries may have short-term effects on breeding colonies and migrating birds that use these habitat types. Gunfire and helicopter noise is particularly likely to flush birds off nests if it occurs close to shore where these birds are nesting or if they are foraging just off shore. Additionally, noise from powerboats that approach the shore could cause birds that are unaccustomed to this activity to temporarily flush off nests.

Any harvested whale would probably be brought to a beach on the Makah Reservation, so nesting colonies (and migrating aggregations) on the reservation would face the greatest risk of disturbance and displacement under the action alternatives. That risk would be associated primarily with the number of whales harvested.

As mentioned in Subsection 3.5.3.2.2, Non-listed Birds and Their Associated Habitats, human-made structures, such as jetties, pilings, and buoys, provide important roosting habitat for cormorants, gulls, and other birds. None of the proposed alternatives would alter any existing human-made structures, or result in the construction of new ones, that may be used by these species for roosting.

Coastal Headlands and Islands

Large numbers of ledge-nesting birds inhabit offshore rocks and islands in the action area. Coastal headlands and islands provide critical nesting, foraging, and overwinter migratory habitat for these species. Species of ledge-nesting birds in the action area may be easily flushed off nest sites, leading to abandonment, predation on eggs or chicks, and subsequent nest failure. In addition, raptors, passerines, and other marine birds also use these habitat types. Noise associated with hunt activities, should

hunting occur close to the headlands and islands, could potentially flush birds off nest sites, similar to the short- and long-term impacts discussed above under Beaches, Bays, and Estuaries. The potential for ledge-nesting species of birds to be affected by whale-hunt-related activities, and the degree of effect, would depend largely on the timing and proximity of any potential hunt-related disturbance. The potential for such disturbance and impacts to these species would depend on the number of days with hunt-related activities, the season in which those activities occur (with activities during the summer breeding season posing a greater risk of disturbance than activities during winter) and the location of the activities (with activities farther off shore posing a smaller risk of disturbance than activities closer to shore).

Nearshore and Inland Marine Habitats

Birds in the action area use the nearshore marine habitat primarily for foraging. A variety of common marine birds also use this area as a migration corridor. Species richness and bird abundance are greatest in winter, although some seabirds may concentrate in large numbers during the summer. Species richness is relatively low in inland marine waters, with richness and bird densities higher in winter than summer. Most species found in this area forage in the winter or during migration.

Nearshore marine habitat is one of the zones where whale hunting could occur under the action alternatives. The nearshore zone occurs mostly within 1 mile (1.6 km) of the shoreline. Vessel noise and human activity associated with hunt activities would displace foraging birds. When a whale is harpooned, all birds foraging within a few hundred feet of the whale hunt would probably flush in response to the sounds of gunfire, helicopters, or other loud devices. Interrupted foraging might lead to increased stress on birds' metabolism, but the short-term impacts would be temporary and localized and not expected to result in long-term effects on the populations as a whole (relative to the No-action Alternative).

Marine Shelf Habitat

Much of this zone is 1 mile (1.6 km) or more off shore, which is further offshore than all previous hunts. This zone provides foraging habitat and a migration corridor for a variety of marine birds, primarily during winter and during late summer/early fall when both residents and migrants are numerous. Because bird densities are lower in this habitat type and no breeding or roosting occurs in this zone, any risks to foraging and migrating birds is also lower, compared to other zones closer to shore.

Oceanic Habitat

The continental shelf hosts the lowest species richness among the habitat types considered in this analysis and is limited to foraging birds as they migrate or residents that forage in deep waters. Species associated with this zone are primarily gulls and terns. This area is approximately 9 miles (14.5 km) off shore (Buchanan et al. 2001), and fewer bird species use this zone than other habitat types closer to shore. It is likely that hunt-related activities under any of the action alternatives would occur closer to shore (i.e., approximately 5 miles (8 km) from shore under Alternative 3 and within 1 (1.6 km) from shore under the other action alternatives). For these reasons, it is likely that any effects of whale hunting on foraging and migrating birds that use these deep ocean waters would be negligible.

4.5.2.2 Prey Availability

Transient killer whales consume gray whales. The analysis considers the likelihood and significance of reduced abundance or availability of prey (i.e., gray whales) for foraging killer whales. Under the action alternatives, the abundance of gray whales in the action area could, but is not likely to, temporarily decrease because of hunting or movement out of the area in response to noise and human presence. Such decreases might reduce the abundance or availability of prey for killer whales, causing them to spend more time foraging and thereby increasing the risk of compromised health. The potential for hunt-related activities under each alternative to result in reduced abundance or availability of prey for foraging killer whales would depend on the number whales likely killed under each alternative and the amount of disturbance likely to occur under each alternative, which in turn would depend on the number of days that scouting, hunting, or training are likely to occur.

Regardless of the number of whales killed or the amount of disturbance that would likely occur under any of the action alternatives, the loss of potential prey to killer whales because of removal of gray whales is unlikely to have individual or population-level effects on killer whales. The endangered Southern Resident killer whales eat fish and do not consume gray whales (or other marine mammals). Gray whales account for only 8 percent of observed predation by transient killer whales on marine mammals on the west coast of North America, and calves (which may not be pursued or killed in a hunt) and juveniles make up the bulk of the gray whales taken (Wade et al. 2006; Steiger et al. 2008). Gray whales are also abundant in the action area. Thus, removal of a maximum of seven adult gray whales per year by whale hunters under the action alternatives is unlikely to affect the prey base of killer whales in the action area. As noted in Subsection 4.4.2.4, Change in Numbers of Gray Whales in the Makah U&A and OR-SVI Areas, it is likely that gray whales would not abandon the Makah U&A or other areas in the PCFG range as a result of limited hunt-related activity.

It is unlikely that any of the action alternatives would affect prey availability for other marine mammals, birds, or sea turtles through disturbance to the food chain (Subsection 4.3, Marine Habitat

and Species). Because of the low likelihood of prey-related effects, potential effects on species other than killer whales are not discussed further.

4.5.2.3 Potential Injury

The analysis considers the likelihood of injury to cetaceans, pinnipeds, sea otters, and sea turtles as a result of being struck by a vessel or impacts associated with a projectile (harpoon, bullet, or grenade) used during the hunt (as measured by the amount of whale hunting activity). It is extremely unlikely that birds would sustain injury from vessels or weapons used in a whale hunt. Any birds that might be near an area where a hunt was underway would almost certainly flush from the area. This analysis, therefore, addresses potential effects on marine mammals or turtles. The risk of injury would depend primarily on the amount of hunt-related vessel traffic in the action area (including Makah vessels and associated protest, media, and law enforcement vessels), which would depend on the number of days with hunt-related trips. Increased levels of vessel activity associated with whale hunting under the action alternatives (compared to the No-action Alternative) would result in an increased risk of animals being struck and injured. For the reasons discussed below, the risk of weapons-related injuries would be extremely small.

4.5.2.3.1 Marine Mammals

Under all of the action alternatives, the potential for any marine mammals to be struck by projectiles would be remote and would be possible only if another animal were mistaken for a gray whale or were immediately adjacent to a gray whale during a strike attempt. Some larger whale species could be mistaken for a gray whale during offshore hunt activities because of similar size. Makah whalers would, however, likely be able to distinguish other species from gray whales because of the characteristic blow of each species, skin color, position of the dorsal fin, behavior, and other characteristics that the whalers are trained to identify. There is a slight possibility that a marine mammal other than a gray whale could be injured by a vessel or an errant projectile associated with the hunt. Other marine mammals do not swim close to gray whales, except transient killer whales that may be preying on gray whales, as mentioned above. For this reason, along with the safety measures the Tribe has proposed including establishing a minimum visibility for hinting and implementing a signal from a lookout (Subsection 2.3.2.2.12, Other Environmental Protection Measures; Public Safety Measures and Enforcement), the chances that a harpoon or errant projectile might strike other marine mammals are considered negligible. Implementation of these measures would ensure a greater likelihood of positively identifying a gray whale before attempting a strike. Therefore, there is a very low likelihood that marine mammals other than ENP gray whales would be struck by projectiles used during a whale hunt under the action alternatives. Real-time differentiation between WNP and ENP

gray whales can be very difficult and may only be possible if very distinctive identifying marks are present on the animal. Photographs and genetic data may be used to identify struck whales as members of the ENP or WNP DPS. In the unlikely event that a WNP gray whale were struck, all hunting would be suspended unless and until NMFS determined that measures had been taken to ensure no additional WNP gray whales are struck during the duration of the permit.

Any killer whales that occur near gray whales would most likely be transients surveying the gray whales as possible prey. The killer whales would most likely associate only with female gray whales with calves, focusing on the calves as prey. Under all of the action alternatives, no strikes would be allowed on calves or adults accompanied by calves. Killer whales would probably not be near gray whales targeted by whale-hunt activities because of the age and size of the targeted whales. Makah whalers are unlikely to mistake a killer whale for a gray whale, and killer whales would most likely not remain close enough to whale hunting activities to be hit by an errant harpoon or projectile. For these reasons, the chances of a killer whale being struck by a harpoon or projectile during a hunt would be negligible.

It is unlikely that hunt-related activities could result in injury to marine mammals as a result of a ship (vessel) strike or propeller injury. As discussed in Subsection 3.4.3.6.8, Ship Strikes, ships at least 263 feet (80.2 m) long that travel at least 14 knots cause most of the lethal or severe injuries to whales. Vessels engaged in a hunt and associated activities would be much smaller. The largest vessel involved in the previous hunts was the 95-foot (29-m) protest vessel M/V *Sirenian*, which remained in Neah Bay during most hunt activities. Vessels engaged in and monitoring the hunt would travel mostly at the rate of the human-powered canoe for all action alternatives except Alternative 3, which would involve a motorized hunt vessel, although law enforcement vessels might have to move more rapidly to intercept protest vessels violating the MEZ.

Because of their keen acoustic capabilities, killer whales would be aware of vessels in the area and would likely move away before the vessels were close enough to cause injury. Killer whales are adept, proficient swimmers, and they would most likely avoid vessels associated with the hunt. Other marine mammals, including seals, sea lions, and cetaceans (with the possible exception of baleen whales, including gray whales), are also adept, fast swimmers that tend to avoid moving vessels. If they were in the path of a moving vessel, they would likely dive below and away from the vessel and out of harm's way. Sea otters are relatively slow swimmers (compared to pinnipeds) and might approach vessels when near shore. However, any sea otters near hunt activities would probably swim rapidly away or dive below and away from oncoming vessels.

4.5.2.3.2 Sea Turtles

Sea turtles are slow swimmers and are susceptible to collision with vessels. Under the action alternatives, whale hunts and associated activities would result in temporary and localized increases in the number of vessels near a whale hunt. Chase boats engaged in a whale hunt, as well as protest vessels and law enforcement vessels, could inadvertently strike a turtle as it surfaced for air, causing injury or death. The potential for injury to sea turtles as a result of vessel strikes associated with a hunt would be extremely low, however, because of the low abundance of these species throughout their range, including the action area. Leatherback turtles would have a higher likelihood of encountering vessels than the other species (green, loggerhead, and olive ridley), which are strictly warmer water species found only infrequently off the Washington coast. However, given that leatherback turtles only rarely occur off the coast of Washington, the likelihood of such incidents would be negligible.

4.5.3 Evaluation of Alternatives

The effects of the seven alternatives would differ among individual species and species groups (including those identified by habitat association) depending on their use of and occurrence in the action area. For example, hunt-related activities under the action alternatives would more likely affect certain pinnipeds than most cetaceans (except gray whales), given characteristics of their foraging behavior and distribution in the action area. Pelagic species (e.g., sperm whales, leatherback turtles) would less likely be affected by the action alternatives than those that commonly occur in the coastal environment (e.g., harbor seals, bald eagles). Among pinnipeds, harbor seals and California sea lions use haulout sites in the action area (Subsection 4.5.2.1.1, Marine Mammals (Excluding Gray Whales)). Those species would, therefore, more likely experience effects of hunt-related activities than elephant seals or fur seals, which do not breed or haul out in the area.

The potential for hunt activity to result in disturbance, reduced prey availability, or injury to wildlife would depend on the timing of the hunt, the location of the hunt, and the number of days with hunt-related trips. Hunting that takes place at a time when a species is present (particularly breeding) in the action area would have a higher likelihood of affecting that species than hunting that takes place when the species is not present in the action area. In addition, hunting that takes place farther off shore (as under Alternative 3) would have a lower likelihood of affecting species that are present on the rocks and islands closer to shore. The more days of hunting that occur, the more potential there is for effects on wildlife. As mentioned above, this analysis assumes that the amount of hunt-related activity would be the same on any given day of a hunt. Thus, each day of hunting during a given season would present the same potential for effects on wildlife.

4.5.3.1 Alternative 1, No Action

Under the No-action Alternative, no whale hunt would be permitted, and no whale hunting or associated activities (e.g., monitoring, protests, and law enforcement) would be authorized. Levels of noise and human presence in the action area would continue to vary with time and location but not be altered by this alternative. Similarly, under the No-action Alternative, neither prey availability nor the risk of injury or death from collision or projectiles would be affected.

Current trends in the status of health, abundance, and habitat conditions for wildlife species would likely continue, including state and federal conservation efforts pursuant to the ESA, MMPA, Migratory Bird Treaty Act, and Bald and Golden Eagle Protection Act. Prohibitions on take under these statutes would continue and could require permits from NMFS and USFWS for some activities. For all species (listed and non-listed), direct mortality from anthropogenic sources would be expected to remain at current levels, as well as natural mortality from predation, disease, and other sources.

Some marine mammals, specifically those in the coastal environment (e.g., harbor seals, California sea lions, Steller sea lions, and sea otters), and most birds and turtles would continue to encounter noise and vessel traffic from sport and commercial fisheries vessels, sight-seeing boats, and other sources such as military vessels. Effects of such activities on these species at current levels are reflected in the species' current status and trends.

Availability of gray whales as prey to transient killer whales would continue to be variable as the gray whale population naturally fluctuates. The timing and magnitude of killer whale foraging efforts on gray whales would be unaffected by this alternative. The prey base for other species (e.g., other cetaceans, pinnipeds, sea otters, and birds) would continue to vary as a result of natural events and human perturbations such as fishing. Ongoing variations in prey abundance would have varying effects on individual species.

A small number of marine mammals in the coastal environment would continue to be exposed to vessel traffic. This might result in vessel strikes from commercial and recreational vessels. Turtles, which are slower swimmers, may be more susceptible than other species to vessel strikes. Implementation of the No-action Alternative would not result in any increase in current low levels of injury as a result of ship strikes.

4.5.3.2 Alternative 2, Tribe's Proposed Action

Under Alternative 2, hunt-related trips would likely occur on approximately 60 days from December through May each year, primarily during April and May. An average of four whales could be harvested per year, with no more than five harvested in a single year. No more than seven whales could be struck

per year. Based on estimates of the number of rifle shots or grenade explosions per whale harvested, Alternative 2 would be likely result in as many as 64 rifle shots or 12 grenade explosions annually (Subsection 4.1.2.5, Potential Number of Shots Fired or Grenade Explosions).

As part of this alternative, the Tribe would not approach within 200 yards (183 km) of Tatoosh Island or White Rock during May to minimize disturbance to feeding and nesting seabirds. No hunting would occur from June 1 through November 30, additionally protecting nesting seabirds during the fledging and post-fledging period. Subsection 4.5.2.1, Disturbance, describes the amount of vessel and aircraft activity expected to occur on any given day of hunting.

4.5.3.2.1 Marine Mammals

Under Alternative 2, changes in disturbance levels, prey availability, and the potential for physical injury on approximately 60 days per year with hunt-related trips could lead to an increased risk to marine mammals other than gray whales, compared to the No-action Alternative (effects on gray whales are addressed in Subsection 4.4, ENP Gray Whale). The greatest potential for effects would be from vessel and noise disturbance. For all marine mammals addressed in this analysis, these effects would be as described in Subsection 4.5.2.1.1, Marine Mammals (Excluding Gray Whales). The intensity of the effects would depend on the number of occasions on which such disturbance occurred (related to the number of days of hunting) and the portion of the animals' life history during which they occurred (hunt timing). Any effects would probably be temporary (lasting for a few minutes to a few hours) and localized (occurring close to the hunt), and would probably not have lasting deleterious effects on individuals or populations. For all species, the number of animals close enough to hunting activities to be disturbed would likely be low.

As discussed in Subsection 4.5.2.2, Prey Availability, the potential for whale hunting activities under Alternative 2 to affect prey availability for killer whales would be minimal, as gray whales are generally abundant in the action area, and hunting regulations would prohibit the killing of calves, one of the primary targets of killer whales. Any marine mammals in the immediate vicinity of a gray whale during a strike attempt could be exposed to an elevated risk of injury associated with as many as 64 rifle shots or 12 grenade explosions annually. As discussed in Subsection 4.5.2.3, Potential Injury, the likelihood that any marine mammals might sustain an injury from a vessel or errant projectile would be extremely remote.

4.5.3.2.2 Other Marine Wildlife

Under Alternative 2, effects associated with whale-hunt activities could lead to an increased risk to birds and turtles compared to the No-action Alternative. The greatest potential for effects on most species would be from vessel and noise disturbance, as described in Subsection 4.5.2.1.2, Other Marine

Wildlife. Such effects would probably be temporary (lasting for a few minutes to a few hours) and localized (occurring near the hunt). For all species, the number of animals close enough to hunting activities to be affected by disturbance would most likely be low. Any disturbance would be localized and of short duration and would probably not cause lasting deleterious effects for individuals or populations. As discussed in Subsection 4.5.2.3, Potential Injury, the likelihood that any sea turtles might sustain an injury from a vessel or errant projectile would be extremely remote. The following discussions provide additional information about the potential effects of Alternative 2 on bald eagles and marbled murrelets, followed by an analysis of the potential effects on other species and their associated habitats. Bald eagles and marbled murrelets are addressed individually because they have a regulatory status indicating heightened management concern (i.e., listing status under the ESA or the Bald and Golden Eagle Protection Act) and more than a minimal likelihood of being affected by whale hunting activities.

Bald Eagle

Most whale hunting under Alternative 2 would likely occur during April and May, coinciding with the early portion of the breeding season for bald eagles and leading to increased risks over the No-action Alternative. If any eagles were disturbed and flushed from their nests, they might abandon their nests, particularly if the disturbance occurs before chicks hatch in May, resulting in loss of that year's chicks. However, most hunt-related activities would occur 1 to 2 miles (1.6 to 3.2 km) off shore and would thus be unlikely to disturb eagles at active nests.

Marbled Murrelet

Under Alternative 2, there could be an increased risk to marbled murrelets compared to the No-action Alternative. Hunting during April and May would have the potential to disturb adult murrelets foraging at sea, potentially reducing the amount of prey brought to chicks. Pre-breeding behaviors such as courtship and pair-bonding may also be affected during this period. The likelihood of any disturbance would be low, however, because hunt-related activities would occupy a small proportion of the action area at any given time and hunt-related activities occur on a limited number of days each year. Marbled murrelets would likely be able to find foraging opportunities in areas where no disturbance would occur. In addition, there would be no potential for hunt-related disturbance during most of the breeding season, which extends from April 1 through September 15.

Non-Listed Marine Birds and Their Associated Habitats

Under Alternative 2, changes in noise and activity levels on approximately 60 days with hunt-related trips could result in the disturbance of birds in the action area. Some hunts could occur during winter and during the spring migratory period, when large numbers of marine birds use beaches, bays, and

entrances to estuaries. Hunts during the spring months could also result in disturbance of birds that are nesting on most coastal headlands and islands. The exceptions would be Tatoosh Island and White Rock; tribal hunters would be prohibited from approaching within 200 yards (183 km) of those locations during May to minimize disturbance of feeding and nesting seabirds during the breeding season.

Compared to the No-action Alternative, Alternative 2 would result in a greater potential for disturbance to breeding, roosting, and migrating birds. Depending on the severity of the effects, some birds' nesting attempts could fail. It is unlikely, however, that such occurrences would result in long-term effects on local populations of species that breed in the action area. Many individuals may already be acclimated to a high level of human disturbance, especially in the northern portion of the Makah U&A (e.g., approximately 25,000 to 47,000 annual angler trips out of Neah Bay (Table 3-28), along with other commercial and recreational vessel and aircraft traffic). Furthermore, the noise and human activity associated with harpooning, securing, and dispatching a whale would be temporary, short-term, and intermittent.

4.5.3.3 Alternative 3, Offshore Hunt

Alternative 3 would include the same hunting season and the same limits on the number of whales harvested as Alternative 2 but would prohibit Makah hunters from making an initial strike on a gray whale within 5 miles (8 km) of shore. Alternative 3 would not include a prohibition on approaching within 200 yards (183 m) of Tatoosh Island or White Rock, because both of these islands are far less than 5 miles (8 km) off shore and are outside the area where most hunt-related activities would occur. As under Alternative 2, vessel and aircraft noise associated with hunt-related trips under Alternative 3 would likely occur on approximately 60 days from December through May each year, mostly during April and May, and there would be as many as 64 rifle shots or 12 grenade explosions annually.

Based on the similarities between the two alternatives, Alternative 3 would be expected to have a similar potential as Alternative 2 for increased risks to birds, turtles, and marine mammals other than gray whales, compared to the No-action Alternative. The increased risks would primarily be associated with changes in disturbance levels on approximately 60 days with hunt-related trips.

Compared to Alternative 2, the restrictions under Alternative 3 on hunting activities within 5 miles (8 km) of shore would be expected to reduce the potential for disturbance or injury of wildlife species during a whale hunt. Possible adverse effects on marine mammals, seabirds, and sea turtles foraging in sanctuary and refuge waters or using refuge lands for resting or breeding would be reduced because of the prohibition on making an initial strike on a gray whale within 5 miles (8 km) of shore. All of the locations in the action area that are used by wildlife at periods of elevated sensitivity to disturbance

(e.g., nesting areas, haulouts) are associated with landscape features (e.g., coastal headlands, islands) that are less than 5 miles (8 km) from shore (Subsection 3.5.3, Existing Conditions). Because less hunt-related activity would occur within 5 miles (8 km) of shore, the increased potential for adverse effects on wildlife under Alternative 3, compared to the No-action Alternative, would therefore be slightly less than, the increased potential under Alternative 2.

Hunting in areas more than 5 miles (8 km) off shore would not be expected to increase the risk of disturbance to any wildlife species that would not otherwise be exposed to hunting activities closer to shore. Nearly all of the cetacean species identified in Subsection 3.5.3.1, Marine Mammals, typically occur in continental slope waters and further off shore, beyond where proposed hunting would likely occur. Safety considerations and logistical constraints would likely keep hunting vessels as close as possible to the 5-mile (8-km) limit, whereas continental slope and deeper offshore waters occur beyond the continental shelf, which is generally 15 to 40 miles (24.1 to 64.4 km) wide in the action area (Subsection 3.3.3.2.1, Physical Features and Processes). Of the species that are more likely to occur closer to shore (including porpoises, seals, sea lions, sea otters, birds, and sea turtles, as well as some whales), none would be expected to occur in greater densities 5 miles (8 km) off shore than in waters 1 to 2 miles (1.6 to 3.2 km) off shore (i.e., the area where most hunt-related activities would be expected to occur under the other action alternatives)(OBIS-SEAMAP 2023).

4.5.3.3.1 Marine Mammals

Under Alternative 3, hunting activities would occur off shore and beyond the range of pinniped haulouts. Therefore, it is expected that Alternative 3 would have less risk of disturbing pinnipeds than Alternative 2 but increased disturbance risks compared to the No-action Alternative. The increased risks would be associated with changes in disturbance levels on approximately 60 days with hunt-related trips. As under Alternative 2, the potential for whale hunting activities to affect prey availability for killer whales would be minimal, as gray whales are generally abundant in the action area and hunting regulations would prohibit the killing of calves, one of the primary targets of killer whales. Similarly, for the reasons identified in Subsection 4.5.2.3, Potential Injury, the likelihood that any marine mammals might sustain an injury from a vessel or errant projectile would be extremely remote. As discussed previously in the overall analysis of the effects of Alternative 3 on wildlife, restrictions on hunting activities within 5 miles (8 km) of shore would be expected to reduce the potential for disturbance or injury of marine mammals other than gray whales during a whale hunt, compared to Alternative 2.

4.5.3.3.2 Other Marine Wildlife

Under Alternative 3, hunting activities would occur off shore and beyond the range of seabird roosting sites and rookeries. Therefore, is expected that Alternative 3 would have less risk of disturbing seabirds than Alternative 2 but increased disturbance risks compared to the No-action Alternative. The increased risks would be associated with changes in disturbance levels on approximately 60 days with hunt-related trips. As discussed in Subsection 4.5.2.3, Potential Injury, the likelihood that any sea turtles might sustain an injury from a vessel or errant projectile would be extremely remote.

As discussed previously in the overall analysis of the effects of Alternative 3 on wildlife, restrictions on hunting activities within 5 miles (8 km) of shore would be expected to reduce the potential for disturbance or injury of birds and sea turtles during a whale hunt, compared to Alternative 2. Nesting areas, where birds (including bald eagles) would be most sensitive to disturbance, are located along the coastline and on offshore rocks and islands and are less than 5 miles (8 km) from shore. As discussed in Subsection 3.5.3.2.1, ESA-Listed Species and Designated Critical Habitat, only a small proportion of the marbled murrelets observed in the action area have been found more than 2 miles (3.2 km) from shore.

4.5.3.4 Alternative 4, Summer/Fall Hunt

Under Alternative 4, the hunting season would extend from June 1 through November 30 instead of December through May. As under Alternative 2, the Tribe would not approach within 200 yards (183 km) of Tatoosh Island or White Rock; this restriction would remain in effect during the entire hunting season (June through November). The maximum number of whales harvested under current conditions would be limited to one ENP male whale every other year. Based on the expectation that locating and striking a known ENP male would take no more than 7 days (Subsection 4.1.4, Alternative 4), vessel and aircraft noise associated with hunt-related trips would be likely to occur on approximately 7 days every other year, or 3.5 days per year on average. Alternative 4 may result in as many as 16 rifle shots or 3 grenade explosions every other year, although those values could be even lower if tribal hunters are unable to locate and strike a known ENP male or if a whale is struck and lost (in which case the hunt would be ended for the year).

Alternative 4 would result in increased risks to birds, turtles, and marine mammals other than gray whales, compared to the No-action Alternative. The increased risks would primarily be associated with changes in disturbance levels on an average of 3.5 days per year with hunt-related trips. As under Alternatives 2 and 3, the potential for whale hunting activities to affect prey availability for killer whales would be minimal, as gray whales are generally abundant in the action area and hunting regulations would prohibit the killing of calves, the primary target of killer whales. Similarly, for the

reasons identified in Subsection 4.5.2.3, Potential Injury, the likelihood that any marine mammals or sea turtles might sustain an injury from a vessel or errant projectile would be extremely remote.

In contrast to the other action alternatives, whale hunting under Alternative 4 could take place during the summer and fall months when many species in the action area are engaged in activities associated with breeding, such as nesting, incubating, or feeding young. In addition, whale hunting that is directed at PCFG whales would likely target whales that are feeding and may therefore take place closer to shore than hunting under the other action alternatives, which would more likely target migrating whales further off shore. Compared to the other action alternatives, therefore, Alternative 4 would result in a smaller increase, relative to the No-action Alternative, in the number of occasions on which hunt-related activities could result in increased risks to wildlife but a greater potential for each occasion to disrupt key activities such as breeding.

4.5.3.4.1 Marine Mammals

Similar to the other action alternatives, Alternative 4 would be expected to have the potential for increased risks to marine mammals, compared to the No-action Alternative. The increased risks would primarily be associated with changes in disturbance levels on an average of 3.5 days with hunt-related trips each year.

As under the other action alternatives, the potential for whale hunting activities to affect prey availability for killer whales would be minimal, as gray whales are generally abundant in the action area and hunting regulations would prohibit the killing of calves, one of the primary targets of killer whales. Similarly, for the reasons identified in Subsection 4.5.2.3, Potential Injury, the likelihood that any marine mammals might sustain an injury from a vessel or errant projectile would be extremely remote.

To a large extent, the effects associated with each hunt-related trip would be as described in Subsection 4.5.2.1.1, Marine Mammals (Excluding Gray Whales). The potential for hunt-related activities to disturb Steller sea lions or California sea lions would be greater than under Alternatives 2 and 3, because gray whale distributions during the summer and fall are nearshore and more often in proximity to sea lion haulouts. The hunt-related activities may also have a greater potential to adversely affect harbor seals because harbor seals use coastal islands and rocks in the action area for breeding-related activities such as pupping and nursing. Noise and human activity associated with a hunt would have the potential to disrupt these activities. As noted previously, however, the number of animals close enough to be affected by hunting activities would probably be low. For these reasons, as under Alternatives 2 and 3, any effects would probably be temporary (lasting for a few minutes to a few hours) and localized

(occurring close to the hunt), and would probably not have lasting deleterious effects on individuals or populations.

4.5.3.4.2 Other Marine Wildlife

Similar to the other action alternatives, Alternative 4 would be expected to have the potential for increased risks to birds and sea turtles, compared to the No-action Alternative. The increased risks would primarily be associated with changes in disturbance levels on an average of 3.5 days with hunt-related trips each year. Disturbance-related effects would be as described in Subsection 4.5.2.1.2, Other Marine Wildlife, and would probably be temporary (lasting for a few minutes to a few hours) and localized (occurring only near the hunt). As discussed in Subsection 4.5.2.3, Potential Injury, the likelihood that any sea turtles might sustain an injury from a vessel or errant projectile would be extremely remote. The following discussions provide additional information about the potential effects of Alternative 4 on bald eagles and marbled murrelets, followed by an analysis of the potential effects on other species and their associated habitats.

Bald Eagle

Whale hunting under Alternative 4 would occur after May, meaning some hunt-related activities would coincide with the fledging period for bald eagles (after chicks hatch in May), leading to an increased risk of disturbance to pre-fledging chicks, compared to the No-action Alternative. The risk of nest abandonment would be lower than under the other action alternatives, however, because bald eagles are less likely to abandon nests during the latter portion of the nesting season (Subsection 4.5.2.1.2, Other Marine Wildlife).

Whale hunting under Alternative 4 would likely target whales that are feeding in the action area and may, therefore, take place closer to shore than hunting under the other action alternatives. As a result, hunt-related activities may have a greater potential to disturb bald eagles at active nests on shore, compared to the other action alternatives. Because bald eagle nesting territories are generally widely spaced, the number of eagle nests that could be subjected to disturbance from any given hunt-related trip would likely be low.

Whale hunting under Alternative 4 would occur after May, meaning some hunt-related activities would coincide with the fledging period for bald eagles (after chicks hatch in May), leading to an increased risk of disturbance to pre-fledging chicks, compared to the No-action Alternative. The risk of nest abandonment would be lower than under the other action alternatives, however, because bald eagles are less likely to abandon nests during the latter portion of the nesting season (Subsection 4.5.2.1.2, Other Marine Wildlife). For these reasons, as under Alternatives 2 and 3, any effects of Alternative 4 on bald

eagles would probably be temporary (lasting for a few minutes to a few hours) and localized (occurring close to the hunt) and would probably not have lasting deleterious effects on individuals or populations.

Marbled Murrelet

Whale hunting under Alternative 4 would overlap with a substantial portion of the breeding season for marbled murrelets. The breeding season extends from April through mid-September; most hunting under Alternative 4 would be expected to take place during the months of June through September, when the risk of encountering adverse weather and sea conditions would be lowest. Therefore, compared to the other action alternatives and relative to the No-action Alternative, hunt-related activities may have a greater increase in the likelihood of disturbing foraging murrelets, potentially reducing the amount of prey brought to chicks. The likelihood of disturbance would be low, however, because hunt-related activities would occupy a small proportion of the action area at any given time and occur on an average of 3.5 days per year at most. Marbled murrelets would likely be able to find foraging opportunities in areas where no disturbance would occur, although this could be more difficult for birds undergoing a 2-month molt (which occurs during the latter half of the year).

Non-listed Marine Birds and Their Associated Habitat

Under Alternative 4, changes in noise and activity levels on an average of 3.5 days with hunt-related trips could result in the disturbance of birds in the action area. Most hunt-related activities would likely occur during the months of June, July, and August when many birds nest, roost, and forage on and around coastal headlands and islands. Compared to the No-action Alternative, Alternative 4 would result in a greater potential for disturbance to breeding, roosting, and foraging birds. Depending on the severity of the effects, some birds' nesting attempts could fail. As under Alternatives 2 and 3, it is unlikely, that such occurrences would result in long-term effects on local populations of species that breed in the action area. Compared to the other action alternatives, Alternative 4 would result in a smaller increase, relative to the No-action Alternative, in the number of occasions on which hunt-related activities would result in increased risks to marine birds, but a greater potential for each occasion to disrupt key activities.

4.5.3.5 Alternative 5, Split-season Hunt

Under Alternative 5, the hunting season would be 3 weeks in December and 3 weeks in May, in contrast to longer hunting seasons under the other action alternatives. In addition, the landing of a single PCFG whale, or the striking and losing of a single whale, would end the hunt for any given year. Based on the constraints imposed by the hunting season and the PCFG mortality limit, it is expected that the Tribe would harvest up to one whale per year (Subsection 4.1.5, Alternative 5). As under Alternative 2, the Tribe

would not approach within 200 yards (183 m) of Tatoosh Island or White Rock during May to minimize disturbance to feeding and nesting seabirds.

Based on the length of the hunting season, hunt-related trips would likely occur on approximately 22 days in May and December each year, mostly during May. This would decrease to 0 days in years when the hunt is on hiatus to allow the PCFG mortality limit to re-set at one whale. Based on estimates of the number of rifle shots or grenade explosions per whale harvested, Alternative 5 would likely result in as many as 16 rifle shots or 3 grenade explosions annually, or as few as 0 rifle shots and grenade explosions during years in which the hunt is on hiatus.

Alternative 5 would be expected to result in an increase, relative to the No-action Alternative, in risks to marine mammals, birds, and sea turtles. The increased risks would primarily be associated with changes in disturbance levels on approximately 22 days with hunt-related trips. As under Alternatives 2 and 3, the potential for whale hunting activities to affect prey availability for killer whales would be minimal, as gray whales are generally abundant in the action area and hunting regulations would prohibit the killing of calves, one of the primary targets of killer whales. Similarly, for the reasons identified in Subsection 4.5.2.3, Potential Injury, the likelihood that any marine mammals or sea turtles might sustain an injury from a vessel or errant projectile would be extremely remote.

Alternative 5 would include the same restrictions on hunt location as Alternative 2. The potential for any given hunt-related trip to result in adverse effects on birds, turtles, or marine mammals other than gray whales would, therefore, be the same as under Alternative 2. For this reason, this analysis considers the effects on marine mammals and on all other marine wildlife species together. Based on the anticipated number of hunt-related trips (22 under Alternative 5 compared to 60 under Alternatives 2 and 3), Alternative 5 would have an overall lower potential for adverse effects on wildlife than Alternatives 2 and 3. The potential for each trip to disturb wildlife species would likely be higher than under Alternative 3 because most hunt-related activity would occur within 5 miles (8 km) of shore, where the activity would have a greater likelihood of being audible or visible at sensitive locations such as nesting areas or haulouts. Compared to Alternative 4 (under which hunting would be allowed during the summer breeding season for many species), hunt-related activities under Alternative 5 would have a lower potential to disrupt key activities such as breeding because hunting would occur only during the months of December and May.

4.5.3.6 Alternative 6, Different Limits on Strikes and PCFG, and Limited Duration of Regulations and Permits

Under Alternative 6, the waiver and implementing regulations would lapse after 10 years. Therefore, the analysis for Alternative 6 considers effects over a 10-year period.

Alternative 6 would include the same provisions as Alternative 2 regarding the hunt area (including the restriction on approaching within 200 yards (183 m) of Tatoosh Island or White Rock during May), season, and methods and would, therefore, result in the same number of hunt-related trips with the same potential for each trip to result in adverse effects on wildlife. Alternative 6 would include greater restrictions than Alternative 2 on the maximum number of whales that could be killed per year and per 2 years. Based on estimates of the number of rifle shots or grenade explosions per whale harvested, Alternative 6 would likely result in as many as 56 rifle shots or 11 grenade explosions annually over the 10-year waiver period.

Alternative 6 would be expected to result in an increase, relative to the No-action Alternative, in risks to marine mammals, birds, and sea turtles. The increased risks would primarily be associated with changes in disturbance levels on approximately 60 days with hunt-related trips each year over 10 years. As under the other action alternatives, the potential for whale hunting activities to affect prey availability for killer whales would be minimal, as gray whales are generally abundant in the action area and hunting regulations would prohibit the killing of calves, one of the primary targets of killer whales. Similarly, for the reasons identified in Subsection 4.5.2.3, Potential Injury, the likelihood that any marine mammals or sea turtles might sustain an injury from a vessel or errant projectile would be extremely remote.

Alternative 6 would include the same restrictions on hunt timing and hunt location as Alternative 2. The potential for any given hunt-related trip to result in adverse effects on birds, turtles, or marine mammals other than gray whales would, therefore, be the same as under Alternative 2. For this reason, this analysis considers the effects on marine mammals and on all other marine wildlife species together. Based on the anticipated number of hunt-related trips (60), Alternative 6 would have the same overall potential for adverse effects on wildlife as Alternatives 2 and 3. The potential for each trip to disturb wildlife species would likely be higher than under Alternative 3 because most hunt-related activity would occur within 5 miles (8 km) of shore where the activity would have a greater likelihood of being audible or visible at sensitive locations such as nesting areas or haulouts. Compared to Alternative 4 (under which hunting would be allowed during the summer breeding season for many species), hunt-related activities under Alternative 6 would have a lower potential to disrupt key activities such as breeding because hunting would occur during the months of December through May and would not overlap most of the breeding season for most species.

4.5.3.7 Alternative 7, Composite Alternative – Preferred

Under Alternative 7, like Alternative 6, the waiver and implementing regulations would lapse after 10 years. Therefore, the analysis for Alternative 7 considers effects over a 10-year period.

As with the other action alternatives, Alternative 7 would result in an increased risk of impacts to wildlife (other than gray whales) in the action area compared to the No-action Alternative. Under Alternative 7, the hunt would take place within the same geographic area as Alternatives 2, 4, 5, and 6 (the Makah U&A west of the Bonilla-Tatoosh line), without the prohibition on striking whales within 200 yards of Tatoosh Island or White Rock but with other site and time restrictions possible to protect the Olympic Coast National Marine Sanctuary resources.

The hunt timing differs from other alternatives. It would follow a split-season schedule in which hunting would take place December 1 through May 31 during winter/spring hunts and July 1 through October 31 during summer/fall hunts (See Subsection 2.3.7, Alternative 7). Much like Alternative 4, the summer/fall hunting seasons under Alternative 7 would take place when many species in the action area are engaged in activities that are associated with breeding, such as nesting, incubating, or feeding young. Based on estimates of the number of rifle shots or grenade explosions per whale harvested, Alternative 7 would likely result in as many as 40 shots fired and 7.5 grenade explosions per year, on average, over ten years (Table 4-1).

The potential for any given hunt-related trip to result in adverse effects on birds, turtles, or marine mammals other than gray whales would be the same as under Alternative 2 in winter/spring hunts and similar but to a lesser degree than Alternative 4 in summer/fall hunts. For this reason, this analysis considers the effects on marine mammals and all other wildlife species together. To compare the overall impact of Alternative 7 to the impacts of the other six alternatives, we use an annual average number of 37 days with hunt-related trips as well as the annual average number of rifle shots or grenade explosions. Alternative 7 would therefore result in a smaller risk of disturbance to other wildlife than Alternatives 2, 3, and 6 (each with 60 days of hunt-related trips and higher numbers of shots/explosions). As with Alternative 4, however, Alternative 7 would result in a greater potential to disrupt key activities, such as breeding in the summer/fall hunting season. Alternative 7 would result in a greater risk than the No-action Alternative (0 days and 0 shots/explosions), as well as Alternatives 4 and 5, each with less than 22 days of hunt-related trips and fewer than 32 shots and six explosions. If the Tribe does not receive authorization to hunt during some or all of the winter/spring hunting seasons, the overall impacts of Alternative 7 on other wildlife could be lower than estimated here; however, it is not possible to determine the likelihood and magnitude of such a scenario in such a way as to compare it against the other six alternatives.

Implementing a low abundance threshold for the ENP stock may reduce the impacts on other wildlife below those already analyzed under Alternative 7 without a threshold. To compare the relative impacts of Sub-alternatives 7(a), 7(b), and 7(c) on other wildlife, we consider the relative likelihood of

triggering the low-abundance threshold of each sub-alternative. Sub-alternative 7(c) carries the highest likelihood of reducing the number of authorized hunting years and, therefore, the annual average number of hunt-related trips, rifle shots, and explosive projectiles used over the waiver period. Sub-alternative 7(a), on the other hand, is most likely to allow hunting to occur during all 10 years of the proposed waiver period. As such, of the three sub-alternatives, 7(c) could result in the lowest potential impact to other wildlife while 7(a) could result in the greatest potential impact.

4.6 Economics

4.6.1 Introduction

This subsection addresses the potential for the alternatives to affect economic conditions in the action area. Whale-hunt-related activities have the potential to affect tourism, the household use of whale products, the whale-watching industry, shipping, sport and commercial fishing, and hunt-related management and law enforcement. As discussed in Subsection 3.6, Economics, the labor force residing on the Makah Reservation in 2021 was about 691 persons, or approximately 2 percent of the total wage and salary workforce in Clallam County. Total personal income for the Makah Reservation is probably an even smaller proportion of countywide total personal income because per capita income of reservation residents is substantially lower than countywide per capita income (Subsection 3.6.3.2.3, Personal Income). Because the economic contribution of the Makah Reservation to the countywide economy is so small, the potential for any changes on the reservation under the alternatives to have a noticeable effect on economic conditions in Clallam County as a whole is negligible. Moreover, economic effects outside the reservation are expected to be negligible in the context of the countywide economy. For these reasons, potential effects on Clallam County as a whole will not be addressed in this analysis.

One potential economic effect of the action alternatives that is not included in the analysis in the following subsections is the economic burden on individuals or households engaged in hunting if the cost of hunting is borne by individuals rather than by the tribal government. In 2002, the Makah Tribal Council decided not to provide financial support for a hunt, leaving it up to whale-hunting families to support any hunts, consistent with tribal tradition. However, the Council did not indicate whether it would financially support future hunts should they be authorized. If individual families were to finance hunts under the action alternatives, the economic impacts on some Makah households could be substantial, given the high costs of supplies and services necessary to participate in the numerous activities related to whale hunting. Aside from the expenses of actually engaging in the hunt, there would be the costs of acquiring seagoing canoes and other whale-hunting equipment, training time, and hosting ceremonial feasts. These costs must be viewed in the light of both the depressed economic

situation of many Makah households (Subsection 3.6.3.2.3, Personal Income) and the Makah Tribe's restriction that prohibits tribal members who participate in a whale hunt from receiving monetary compensation. It is likely that a family would launch its own whale hunting enterprise only if that family were economically successful during the several months between whale hunting seasons.

These economic constraints would likely affect the number of hunts that could take place in any given year. However, the magnitude of the household costs arising from the whale hunt, and the distribution of these costs across the Makah community, are not reasonably foreseeable because of uncertainty about what costs families would bear rather than the community as a whole, and about the number of families that would organize a whale-hunting crew.

Also, under Alternatives 6 and 7, the waiver and implementing regulations would lapse after 10 years, and it is not possible to predict whether they would be replaced with a new waiver and implementing regulations or what the terms of any new waiver and regulations would be. Assuming the Tribe wished to continue hunting after a waiver expired, Alternatives 6 and 7 could result in added costs to the U.S. government, the Makah Tribe, and interested parties if a new waiver were pursued.

4.6.2 Evaluation Criteria

The criteria used to determine the potential for effects on economic conditions under the alternatives include the potential change in revenue, employment, and/or economic value associated with (1) tourist-related business activity; (2) household consumption of whale products, and manufacture and sale of traditional handicrafts; (3) the whale-watching industry; (4) commercial shipping and sport and commercial fishing; and (5) hunt-related management and law enforcement. The following subsections discuss these matters in greater detail and identify how the effects of the alternatives may be assessed and differentiated.

4.6.2.1 Tourism

Tourism is a relatively large industry in Clallam County; visitors spent $300.7 million in the County in 2018 (Table 3-21). Spending in the food and beverage services sector accounted for about 36 percent of total visitor spending and in the accommodations sector accounted for about 21 percent of total visitor spending. Figures are not available for the amount of revenue generated by reservation tourism and recreation or the number of jobs and amount of personal income that depend on visitor spending, but about 7 percent of jobs (including arts, entertainment, recreation, accommodation, food services, and information) held by Makah Reservation residents in 2021 were in sectors that depend directly on tourism (Table 3-27).

Activities associated with a whale hunt, including the hunt itself and harvest-related ceremonies and celebrations, have the potential to affect the tourism industry in Clallam County by changing the number of visitors to the area and their travel expenditures. Persons seeking opportunities to view a whale hunt may visit trails and beaches in the Olympic National Park, OCNMS, and the Makah Reservation. It is possible that visitation to these areas would increase under the action alternatives compared to the No-action Alternative, as interested observers seek vantage points to view the hunt. Also, there is the potential for persons attracted to the area by hunt-related activities (such as protesters, law enforcement officers, media representatives, or other observers) to engage in other activities, such as camping, sightseeing, or wildlife viewing. Spending associated with these activities could increase under the action alternatives (relative to the No-action Alternative).

As described in Subsection 3.6.3.3.1, Summary of Economic Effects of the Makah Gray Whale Hunts, no quantitative information is available concerning the economic effects of the Makah Tribe's practice whale hunt exercises in late 1998 or their whale hunting in the spring of 1999 and of 2000. Protests and media coverage of these events may have temporarily generated an increase in the number of people in the area who might have sought accommodations and services in the communities of Neah Bay, Clallam Bay, and Sekiu. Some anecdotal information suggests this was the case, while other anecdotal information suggests it was not. No economic data demonstrate that the influx of visitors during previous hunt-related events resulted in an increase in the number of rooms rented or in other economic activity. Given the likely influx of visitors coming to Neah Bay to observe, protest, or report on the hunt, or to participate in tribal ceremonies and celebrations, it is reasonable to expect there would be a short-term increase in tourist-related business activity associated with these visitors. Any short-term effect is likely to be minor and may diminish as more hunts occur. Subsection 3.6.3.3.1, Summary of Economic Effects of the Makah Gray Whale Hunts, indicates that there were fewer protesters at the 2000 hunt than the 1999 hunt. Over the long term, there is no information suggesting that the hunts in 1999 and 2000 had any lasting effect on tourism in Clallam County or Neah Bay. Thus, while a whale hunt might attract visitors to the Neah Bay area, it is likely that any positive effect would be short-term and minor.

In addition to attracting visitors to Clallam County when hunt-related activities occurred, Makah whale hunting might have a broader and longer-term positive effect on the Tribe's efforts to bolster the tribal tourism sector of the reservation economy. As Jollie and Green (2001) report:

> Visitors mostly learned about the Makah Tribe through whaling notoriety and Olympic National Park and hiking trail advertisements. . . . The controversy over whaling has had a direct impact on tourism as people are drawn to the area by media reporting of the whaling events.

Controversy surrounding resumption of whale hunting has rekindled international interest in the Makah people at the same time as tribal tourism and other types of cultural tourism are rapidly gaining popularity throughout the world (Washington State Parks 2004). The Makah Tribe has been an active participant in programs by Washington State and the Affiliated Tribes of Northwest Indians to market tribal tourism (Affiliated Tribes of Northwest Indians undated; Jollie and Green 2001; May 2001). Although the government sector is the dominant employer on the Makah Reservation (Subsection 3.6.3.2.2, Employment), tourism is also considered a key element of the local economy (Subsection 3.6.3.2.4, Contribution of Tourism to the Local Economy).

Any positive effects of a whale hunt on tourism (both locally and county-wide) could be offset to some extent if opposition to the hunt resulted in boycotts of Olympic Peninsula tourism activities, including boycotts of Neah Bay specifically. Subsection 3.6.3.3.1, Summary of Economic Effects of the Makah Gray Whale Hunts, describes efforts to organize a boycott of the Makah nation, but no available information indicates the boycott had any effect on tribal enterprises. Similarly, there is no evidence that calls for boycotts of Olympic Peninsula tourism had any negative economic impact on tourist-related businesses in the area. It is possible that some persons who might participate in a boycott would not do so if the whale hunting was conducted with restrictions on hunt timing, area, or the number or identity of whales that may be struck. However, protest activities and vocal opposition to the hunt have come from groups that have expressed opposition to whale hunting under any conditions (Subsection 4.8.3, Evaluation of Alternatives [Social Environment]). Persons opposed to whale hunting under any conditions would be likely to participate in a boycott under any of the action alternatives.

The effects on tourism would depend primarily on (1) the number of days with hunt-related trips, (2) the anticipated number of persons who might be attracted to the area by hunt-related activities (such as reporters, protesters, or observers), and (3) the anticipated amount, intensity, duration, scope, and content of media coverage. The second two factors are also discussed in Subsection 4.12, Aesthetics.

4.6.2.2 Household Use of Whale Products

Under the No-action Alternative (current conditions), Makah tribal members do not have the opportunity to consume freshly harvested whale products. Drift whales or whales incidentally caught in fishing operations may provide an opportunity to consume whale products or to produce hand-crafted articles made from whale products (Subsection 2.4.2, Subsistence Use of Drift Whales). If a whale hunt were authorized under any of the action alternatives, Makah tribal members could consume the meat, blubber, and other edible products obtained from harvested whales (Subsection 2.3.2.2.11, Whale Product Use and Distribution). Moreover, within the borders of the United States, tribal members could share edible whale products from any hunt with relatives of participants in the harvest, with others in

the local community (both non-relatives and relatives), or with persons in locations other than the local community with whom local residents share familial, social, cultural, or economic ties.

Subsistence food products from a whale would not generate revenue through market sales but would meet nutritional needs of Makah families. Thus, attaching a dollar value to food products from harvested whales is difficult. Nevertheless, the harvest of whales for food has economic value to households as they potentially replace foods that families would otherwise have to purchase. The distribution of subsistence products through sharing networks makes it likely that many households and individuals would enjoy the economic benefits of a whale harvest.

In household surveys conducted in 2001, 2006, 2011, and 2017, 80 to 90 percent of survey respondents expressed an interest in increased access to whale products (Subsection 3.10.3.5.1, Makah Whaling). Considering the numbers of whales that could be harvested under the action alternatives and the customary sharing of subsistence resources among tribal members (Subsection 3.10.3.5.2, Makah Subsistence Consumption), the per capita economic value of whale products as a food resource would probably be small. The Tribe's most recent needs statement to the IWC (Renker 2018) estimates that harvesting an average of four gray whales per year would yield 8 to 20 pounds (4 to 9 kg) of meat per capita and 16 to 20 pounds (7 to 9 kg) of oil or blubber per capita (and a somewhat smaller amount of whale oil after rendering). Nevertheless, the reintroduction of whale food products into the Makah community could help offset potential food shortages if other subsistence resources diminish, and could prevent people from having to spend cash to replace subsistence foods (Renker 1996; 2007; 2012; 2018).

In addition, the Makah Tribe could create and sell or offer for sale authentic articles and native handicrafts and clothing, including artwork, made from non-edible whale products, within the United States under any of the action alternatives (Subsection 2.3.2.2.11, Whale Product Use and Distribution). A whale hunt would likely increase the availability of non-edible whale products, compared to the No-action Alternative, for the manufacture and sale of traditional handicrafts. The Makah have a long tradition of manufacturing carvings, baskets, and other items for sale to collectors and tourists (Erikson 2003), and "[t]ribal artisans also produce carvings, jewelry, and silk screen designs for sale in local shops and regional galleries" (Subsection 3.6.3.2.1, General Description of the Local Economy). Seventy-six percent of Makah households expressed a desire for whale bones, possibly to revitalize certain crafts (Subsection 3.10.3.5.1, Makah Whaling). Handcrafted articles made from whale products could become sources of income for some Makah households and a means of perpetuating indigenous art forms and crafts. Renker (1996) notes that the bones of a gray whale incidentally caught in 1995 were distributed to Makah artists through the Makah Cultural and Research

Center, which is one of the largest retail outlets of Makah artwork on the reservation (Erikson 2003). According to Renker (2007), some Makah tribal members indicated they were disappointed that the bones of the whale harvested in the 1999 hunt were not made available to the community for private use. They were used by the local school for a bone preservation project instead (Subsection 3.10.3.5.1, Makah Whaling) and currently are on display in the Makah Cultural and Research Center.

The amount of whale products for household consumption and the manufacture and sale of traditional handicrafts would depend on the number of whales that could be harvested.

4.6.2.3 Whale-watching Industry

Whale-watching is not economically important in Clallam County with few whale-watching opportunities available, but there are larger whale-watching operations outside and adjacent to the county in Westport, Washington and Vancouver Island, British Columbia (Subsection 3.6.3.3.2, Commercial Value of Whales). Information on the current numbers of whale-watching expeditions, whale-watching passengers, whale-watching revenues in these areas, or people employed in the whale-watching sector is not available. A Makah gray whale hunt could affect whale-watching revenues or employment if a hunt caused prospective passengers to avoid whale-watching tours; if a hunt occurred in the vicinity of whale-watching operations and disturbed whales, causing them to move away from the area; or if whales altered their behavior as a result of hunting and avoided whale-watching vessels. For the reasons discussed below, it is unlikely that whale-hunting under any of the action alternatives would have more than a negligible effect on whale-watching revenues or employment within or outside the action area through any of these scenarios.

First, while negative publicity about Makah whale hunting could reduce public participation in whale watching in general, there is no information demonstrating such an effect. In addition, it is unlikely that whale-hunting activities under the action alternatives would interfere with whale-watching tours in the action area. There is no evidence that whale-watching operators conduct tours targeting gray whales in the action area. Much of the gray whale watching in Clallam County is from land-based locations along its seashore, although whale-watching charters may be available through some sport fishing boat operators (Subsection 3.6.3.3.2, Commercial Value of Whales). While gray whale watching is an important tourist activity off Westport, located on Washington's Pacific coastline at Grays Harbor (Subsection 3.6.3.3.2, Commercial Value of Whales), that area is approximately 80 miles (129 km) south of the Makah U&A. Several of Westport's charter boat businesses offer whale-watching trips from March through May, when gray whales can be viewed just off the coast during their annual migration. It is unlikely that these tour operators would expend the time and fuel to travel to the Makah U&A when gray whales are present immediately off shore. Whale-watching tours from Westport,

therefore, would be unlikely to encounter hunt-related activities under any of the action alternatives. The gray whales are northbound at that time and pass Westport before reaching the Makah U&A farther north. Whale-hunting activities under any of the action alternatives, therefore, would be extremely unlikely to scare whales away from areas where they may be encountered by whale-watching tours out of Westport, even during the peak tour period of March through May.

Whale-watching is also an important tourist activity off Vancouver Island (Subsection 3.6.3.3.2, Commercial Value of Whales). Although most Vancouver Island-based whale-watching operators focus largely on opportunities for viewing killer whales, they also advertise opportunities for viewing other wildlife, including gray whales. Further, none of these operators describes tours that include the Makah U&A.

It is unlikely that gray whales would respond to a Makah tribal hunt by avoiding whale-watching vessels (Subsection 3.4.3.6.6, Vessel Interactions). ENP gray whales have been exposed to hunting for decades by Chukotka Natives, yet that ongoing hunt has not translated into a general avoidance of boats by gray whales (NMFS 2001a; Hoyt and Hvenegaard 2002). There is no evidence to suggest that hunting by the Makah Tribe would cause a change in behavior that has not yet been demonstrated to result from a far more extensive hunt. ENP gray whale behavior also does not appear to have been affected by other types of human and vessel activity. As described in Subsection 3.4.3.6.6, Vessel Interactions, these whales migrate through waters occupied by large numbers of commercial and private vessels. Off the coast of Los Angeles, California, during the whale-watching season, Rugh et al. (1999) reported that 8 to 12 boats may follow a single whale. The number of approaches incidental to Makah whale hunting would be minor compared to the whales' existing level of exposure to vessels. Similarly, as described in Subsection 4.5, Other Wildlife, any effects of a hunt on other marine mammals that might be a target of whale-watching operators would likely be localized and temporary.

Finally, over time an ongoing hunt could reduce the abundance of whales in the PCFG range by a current maximum of one to five whales per year (or a more likely range of 0 to 2 whales per year depending on the alternative), which could in turn reduce the number of gray whale encounters/sightings experienced during whale-watching tours if more whales do not recruit to replace the harvested whales. However, whale-watching operators are adept at finding whales (especially killer whales) and many advertise their high success rate and guarantee sightings (e.g., Island Adventures 2014; Vancouver Whale Watch 2014), although not necessarily of gray whales. Also, active whale sighting networks typically include reports from whale-watching charters that can make it easier for operators to locate even lone animals or small concentrations of animals, including gray whales (Orca Network 2014; Gless and Krieger 2023). Moreover, because gray whales are not typically the sole or

primary species targeted by most whale-watching operators it is unlikely that a decrease in the numbers of gray whales would appreciably impact the public's incentive to pursue whale watching in the PCFG range.

If a Makah gray whale hunt were to alter gray whale behavior or result in a reduction in gray whale numbers, it is not possible to estimate the amount of decrease that might occur in revenues of whale-watching operators. Current revenues of whale-watching operators are unknown, and there is no information available or that could reasonably be obtained that would allow an estimation of how much whale-watching revenues might decrease if gray whale behavior or numbers were altered by a Makah hunt. The extent to which a Makah hunt had an effect on gray whale behavior or numbers, and a subsequent indirect effect on whale-watching revenues, would depend primarily on factors that could reduce the abundance of whales or cause whales to avoid boats, including the number of whales that could be struck and the estimated number of whales killed or subjected to harpoon attempts and approaches.

4.6.2.4 Shipping and Ocean Sport/Commercial Fishing

Under the No-action Alternative, the value of commercial shipping in Washington State is $90 billion, a substantial proportion of which is the result of shipping that passes through the action area (Subsection 3.6.3.1.4, Commercial Shipping). Between 2017 and 2019, expenditures associated with recreational salmon fishing generated between $601,000 and $721,00 of personal income (in 2021 dollars) in Neah Bay each year, with the recreational groundfish fishery likely accounting for comparable spending levels (Subsection 3.6.3.2.5, Contribution of Ocean Sport Fishing to the Local Economy). Most fishing derbies in Clallam County take place during late spring through early autumn. The value of commercial fish landings at the Port of Neah Bay between 2016 and 2020 ranged from $42.5 to $68.4 million annually (Subsection 3.6.3.2.6, Contribution of Ocean Commercial Fishing to the Local Economy).

If whale hunting restricted the operations of commercial shipping traffic or sport and commercial fishing vessels, it could affect revenues or employment associated with these sectors. Vessels not involved in whale hunting would have to maintain prudent distances from whale hunts as a safety precaution. As discussed in Subsection 2.3.2.2.12, Other Environmental Protection Measures; Public Safety Measures and Enforcement, there would be a moving exclusionary zone (MEZ) with a 500-yard (457-m) radius centered on tribal vessels actively engaged in a whale hunt under any of the action alternatives. No person or vessel would be able to enter the MEZ when it was activated, except for the authorized Makah whale hunt vessel, a media pool vessel preauthorized by the Coast Guard, or another vessel or person preauthorized by the Coast Guard. The requirement to remain outside the MEZ could

increase operating costs if it caused vessels to take longer routes to reach their destinations or could decrease revenues if it prevented fishing vessels from accessing fishing grounds. It is possible that revenues associated with shipping, sport fishing, or commercial fishing could decrease in response to these restrictions.

The small size and limited duration of the MEZ would likely result in negligible disruption of commercial shipping or sport and commercial fishing. The activation of the MEZ may simply displace these activities rather than halt them altogether. Further, as described in Subsection 4.13.2.2, Marine Traffic, hunt-related activities would probably not interfere with commercial shipping traffic because most, if not all, hunting would likely occur within the Coast Guard RNA, which lies almost entirely within the OCNMS area to be avoided.

The potential for any of the alternatives to affect shipping or sport and commercial fishing would depend primarily on the number of times the MEZ would be activated. It is not possible to predict how many times the MEZ would be activated on a given day of hunting, but it is reasonable to expect that MEZ activation would be no more or less likely to occur on one day of hunting compared to another. For this reason, the number of days of hunting is used to indicate the number of times the MEZ would be activated under any of the alternatives. (Note that this analysis differs from many of the other resource area analyses in this EIS because it focuses on days of actual hunting rather than days with hunt-related trips [i.e., hunting or scouting]). For sport fishing operations, the potential for an effect could also depend on the season that hunting is allowed. Sport fishing for salmon occurs during the summer and early fall, while sport fishing for other species occurs year-round (Subsection 3.6.3.2.5, Contribution of Ocean Sport Fishing to the Local Economy). Hunting that occurs on summer days would have a greater potential to affect sport fishing than hunting that occurs on winter days.

4.6.2.5 Management and Law Enforcement

Under the No-action Alternative, NMFS' annual budget for marine mammal management in the West Coast Region during 2012 and 2013 has ranged from $766,000 to $903,000 per year (NMFS 2014a). The overall budget for monitoring the ENP gray whale population is approximately $75,000. Within the ENP gray whale budget, funding has been provided for photo-identification studies of gray whales in local survey areas with one purpose, among others, being management of a potential Makah gray whale hunt. It is uncertain whether NMFS would continue to fund the photo-identification program if a hunt was not authorized. Because no gray whale hunting currently occurs, there are no NMFS observers associated with a hunt.

If a whale hunt were authorized under any of the action alternatives, it is likely that hunting would be monitored and evaluated for its impact on the ENP gray whale population in general and on PCFG

whales in particular. Funding would likely continue for the photo-identification studies aimed at identifying PCFG whales. Estimated annual costs for NMFS for the photo-identification study are $75,000 (NMFS 2014a). Funding would also likely be provided for NMFS and Makah observers during and immediately following a hunt (Subsection 2.3.2.2.12, Other Environmental Protection Measures). The cost of a NMFS observer could be as high as $8,000 per month (i.e., averaging $263 per day) (NMFS 2014a).

If whale hunting by the Tribe engendered protests by whaling opponents, as it has in the past, there would likely be law enforcement operations to maintain order. Past law enforcement activities have involved the United States Coast Guard, NMFS Office of Law Enforcement, the State of Washington, Clallam County Sheriff's Office, and Makah tribal police. Estimated costs for all non-tribal agencies could approach $91,670 per day, with the bulk of costs associated with United States Coast Guard aircraft and vessels (NMFS 2014a) (Table 4-16).

Under any of the action alternatives, costs associated with hunt observers or with law enforcement would depend primarily on the number of days of hunt-related trips (Table 4-1). The costs for hunt observers would increase (relative to the No-action Alternative) by at least the number of days of hunting per year. Given the remoteness of the action area, it is likely that observers would need to be paid for additional days because of travel times to and from Neah Bay.[16] Therefore, we assume that the number of days with hunt-related trips is a better cost estimator. It is not possible to predict the number of days of preparation or protests that would occur for each day of hunting. Estimated enforcement costs for any of the alternatives may therefore be conservative. Costs for photo-identification studies would likely be the same regardless of the action alternative implemented.

4.6.3 Evaluation of Alternatives

The following subsections consider the potential for the alternatives to affect economic conditions both within and outside the action area. Potential effects outside the action area include such things as changes in revenue or employment associated with whale watching and tourism. For each alternative, the discussion addresses the potential effects on tourism, household use of edible and non-edible whale products, the whale-watching industry, commercial shipping, sport and commercial fishing, and management and law enforcement.

Under any of the action alternatives, tourist-related enterprises in and around the action area could experience a minor increase in business activities over the short term compared to the No-action

[16] During the 1999 hunt, the NMFS observer needed a day to travel to Neah Bay after being contacted by the whaling captain, as well as the following day to coordinate with the whaling crew (Gosho 1999).

Alternative. Interested tourists and other visitors would most likely visit the action area to observe the whale hunt and might participate in harvest-related celebrations as media stories raised public awareness of the Makah whale hunt and the Tribe's whale hunting tradition. Some individuals might decide not to visit the action area based on negative publicity about the whale hunt. Overall, it is reasonable to expect more visitors would be drawn to the area than avoid the area as a result of a whale hunt, potentially resulting in a minor short-term increase in tourism-related business activity. The amount of any such potential short-term increase would likely depend on the number of days with hunt-related trips under a particular alternative. Thus, alternatives with more days with hunt-related trips would likely result in a greater increase.

The potential also exists for increased long-term business activity (relative to the No-action Alternative) as a result of expansion of the tribal tourism sector of the reservation economy. Such a potential is likely linked to whether hunting occurs at all and is therefore likely to be similar across all of the action alternatives.

Under any of the action alternatives, the potential for whale products to become available for household consumption and the making and selling of handicraft articles would increase (relative to the No-action Alternative) as a result of the opportunity for tribal members to harvest whales. The amount of any increase would depend on the number of whales likely to be harvested under a particular alternative. Thus, alternatives with higher harvest levels would likely result in a greater increase.

The lowest risk of adverse effects on whale-watching operators, commercial shipping traffic, and sport and commercial fisheries would occur under the No-action Alternative because no whale hunts would be permitted under this alternative. Under any of the action alternatives, it is unlikely that Makah whale hunting would have more than a negligible effect on whale watching, for the reasons described above (Subsection 4.6.2.3, Whale-watching Industry). To the extent such an impact did occur, the amount of risk would probably depend on the number of whales that could be killed, struck, or exposed to harpoon attempts and approaches. Thus, alternatives that result in greater numbers of harvested whales, strikes, harpoon attempts, or approaches would have a greater potential to adversely affect whale-watching operators.

The potential for disruption of commercial shipping traffic and sport and commercial fisheries would likely be negligible because of the small size and duration of the MEZ. To the extent such an impact did occur, the amount of disruption would probably depend on the number of times the MEZ was activated, which would depend on the number of days of hunting. Thus, alternatives that result in more days of hunting would have a greater potential to adversely affect commercial shipping traffic and sport and commercial fisheries.

The potential for economic effects associated with the costs of law enforcement and management would be lowest under the No-action Alternative, while alternatives that involve more days with hunt-related trips and longer hunting seasons could potentially have higher associated costs.

4.6.3.1 Alternative 1, No Action

Under the No-action Alternative, no whale hunt would be permitted and no whale hunting or associated activities (e.g., ceremonies, celebrations, protests, monitoring, and law enforcement) would be anticipated. There would be no potential for visitors to view hunt-related activities in the action area or to participate in harvest-related celebrations. There would also be no potential for media coverage of the whale hunt that might, in turn, generate interest in the Makah Reservation as a cultural tourism destination. Consequently, the level of business activity for tourist-related enterprises in and around the action area would not be expected to differ from the current level.

With the possible exception of products from drift whales, there would be no potential for households to consume whale meat and blubber or use non-edible whale products for the manufacture and sale of traditional handicrafts. There would be no potential for a whale hunt to disrupt the whale-watching industry, commercial shipping, or sport or commercial fishing. Consequently, the economic conditions of the whale-watching industry, commercial shipping, and sport and commercial fishing would probably not differ from current conditions. The lack of whale hunting would make monitoring and enforcement unnecessary, so there would be no additional costs associated with these activities. The current costs for photo-identification studies may or may not continue.

4.6.3.2 Alternative 2, Tribe's Proposed Action

Under Alternative 2, hunt-related trips would likely occur on approximately 60 days from December through May, but primarily during April and May (Subsection 4.1.2.1, Potential Timing of a Hunt and Number of Hunting Days [Alternative 2]). The limit on the number of whales struck would be seven, and the limit on the number of harvested whales would be an average of four per year with a maximum of five in any one year. Approximately 42 whales would be exposed to harpoon attempts and 353 would be approached annually (Table 4-1). Compared to the No-action Alternative, under which there would be no hunting, Alternative 2 would likely result in (1) minor short-term increases in tourism on or near the approximately 60 days per year when hunt-related trips would be expected to occur, (2) an increase of four whales annually available for household use by Makah tribal members, (3) negligible changes in whale-watching revenues, (4) minor increases in the potential for interference with shipping and sport/commercial fishing vessels, and (5) an increase in expenditures for management and law enforcement.

4.6.3.2.1 Tourism

Under Alternative 2, visitors would likely be drawn to the action area on or near the approximately 60 days per year on which hunt-related trips would be expected to occur, potentially creating a minor increase in the level of business activity for nearby tourist-related businesses, compared to the No-action Alternative (under which no visitors would come to the action area to observe whale hunts). The number of whale hunts portrayed in the media would also likely increase compared to the No-action Alternative, possibly increasing public interest in the Makah Reservation as a cultural tourism destination (or, conversely, causing some individuals to avoid the action area because of negative publicity). The increased business activity would likely be short-term (lasting only during the days immediately surrounding hunt-related activities), as visitors would come to observe the hunt and to participate in harvest-related celebrations. Hunting would be allowed from December 1 through May 31 but would most likely occur during April and May. Potential inclement weather during April and May could deter visitors from coming to observe a whale hunt or participate in harvest-related ceremonies.

It is uncertain whether a hunt would result in a long-term increase in tourism. Publicity about the whale hunt could generate interest in the Makah Reservation as a cultural tourism destination, while some individuals might not visit the area because of negative publicity about the whale hunt. Subsection 3.6.3.3.1, Summary of Economic Effects of the Makah Gray Whale Hunts, describes efforts to organize a boycott of the Makah Nation, but no available information indicates the boycott had any effect on tribal enterprises. Similarly, there is no evidence that calls for boycotts of Olympic Peninsula tourism had any negative economic impact on tourist-related businesses in the area.

4.6.3.2.2 Household Use of Whale Products

Compared to the No-action Alternative (under which no whales could be harvested and the Tribe would have access only to drift whales or whales incidentally caught in fishing gear), up to five whales annually could be harvested under Alternative 2, with an average annual harvest of four whales allowed. The limit on the number of PCFG whales killed per year would be three, based on current population estimates (Table 4-3). In addition, only PCFG whales harvested, not whales struck and lost, would be counted toward that limit. It is, therefore, unlikely that limits on PCFG whale mortality would restrict the total number of whales harvested per year under Alternative 2. The hunting season would be restricted to the period from December 1 through May 31, with most hunts likely occurring during April and May. Potential inclement weather during these months would likely affect the number of days the Tribe could hunt, which could affect the Tribe's ability to harvest the full number of whales allowed.

Under Alternative 2, the amount of whale products available for household consumption, and manufacturing and selling of traditional handicrafts would increase relative to the No-action Alternative. The increased availability of whale products would have the potential to replace foods that Makah families would otherwise have to purchase and result in increased income for households that participate in the making and selling of traditional handicrafts. The increase would come from whales the Tribe was actually able to harvest, which would likely be up to four whales annually. The actual number of whales harvested each year could be lower because of the constraints on PCFG whales and the hunting season.

4.6.3.2.3 Whale-watching Industry

Compared to the No-action Alternative (under which no whales would be struck, exposed to harpoon attempts, or approached by hunters), under Alternative 2, up to 7 whales may be struck or killed annually, 42 exposed to unsuccessful harpoon attempts, and 353 approached. As noted above, limits on the harvest of PCFG whales would not be likely to restrict the Tribe's ability to harvest the full number of whales allowed, nor the number of whales struck, exposed to unsuccessful harpoon attempts, and approached. The hunting season would be restricted to the period from December 1 through May 31, with most hunts likely occurring during April and May. Potential inclement weather during these months would likely affect the number of days the Tribe could hunt, which could also affect the number of whales harvested, struck, exposed to unsuccessful harpoon attempts, and approached.

As described in Subsection 4.6.2.3, Whale-watching Industry, there is no information to suggest that individuals would avoid whale-watching tours if a Makah hunt is authorized, and it is unlikely that Makah hunting activities would overlap geographically with whale-watching tours. It is also unlikely that a reduction in the number of gray whales (which are not typically targeted by whale-watching operators) would change public interest in whale-watching tours, nor is it likely that gray whales would respond to a Makah tribal hunt by avoiding whale-watching vessels. As described in Subsection 4.5, Other Wildlife, it is likely that any effects of a hunt on other marine mammals, which might be a target of whale-watching operators, would be localized and temporary. To the extent such an effect might occur under Alternative 2, it is not possible to estimate the amount of decrease that might occur in revenues associated with whale watching. Current revenues of whale-watching operators are unknown, and there is no information available or that could be obtained that would allow an estimation of how much revenues might decrease if ENP gray whale behavior were altered by a Makah hunt.

4.6.3.2.4 Shipping and Ocean Sport/Commercial Fishing

Compared to the No-action Alternative (under which there would be no whale hunts and no activation of the MEZ), activation of the MEZ during hunting on approximately 33 days (Table 4-1) under

Alternative 2 would lead to an increased potential for restricting operations of commercial shipping vessels and sport and commercial fishing. Hunting would likely occur primarily in April and May when there are more suitable hunting days.

The small size of the MEZ and limited duration of activation would likely result in negligible potential for disruption of commercial shipping or sport and commercial fishing. Further, as described in Subsection 4.13.2.2, Marine Traffic, hunt-related activities would probably not interfere with commercial shipping traffic because most, if not all, hunting would likely occur within the Coast Guard RNA, which lies almost entirely within the OCNMS area to be avoided. Also, most sport fishing for salmon occurs outside the time that whale hunting would take place under Alternative 2. Consequently, only minor economic impacts to commercial shipping or sport and commercial fisheries would be expected as a result of implementing Alternative 2.

4.6.3.2.5 Management and Law Enforcement

Compared to the No-action Alternative (under which no whale-hunting or associated protests would occur), Alternative 2 could result in up to 60 days of hunt-related trips and associated commitments of observers and enforcement personnel, vehicles, and equipment. The costs for hunt observers would increase (relative to the No-action Alternative) by at least the number of days of hunting per year (33 days) (Table 4-1). Given the remoteness of the action area, it is likely that observers would need to be paid for additional days because of travel times to and from Neah Bay. Therefore, we assume that the number of days with hunt-related trips (60 days) is a better estimator; costs for a NMFS observer for 60 days could be as high as $15,780 (NMFS 2014a) (Table 4-16) under Alternative 2. It is uncertain whether the existing photo-identification study would continue to be funded under the No-action Alternative. If not, then its continuation under Alternative 2 could represent an increased cost beyond the No-action Alternative.

If whale hunting by the Tribe engenders protests by whaling opponents, as it has in the past, there could also be costs associated with law enforcement activities. These costs would be an increase over the No-action Alternative by the number of days when hunt-related activities (e.g., hunting, protests, and ceremonies) occurred that required a law enforcement presence. Although likely days of hunting (33 days) would represent the minimum number of days on which a law enforcement presence might be required, the number of days with hunt-related trips (60 days) may represent a more reasonable, upper estimate given the past history of interest and protest activity associated with this whale hunt. Estimated costs for all non-tribal agencies could be as high as $5.5 million over the course of 60 days, with the bulk of costs associated with United States Coast Guard aircraft and vessels (NMFS 2014a) (Table 4-16).

4.6.3.3 Alternative 3, Offshore Hunt

Under Alternative 3, as under Alternative 2, hunt-related trips would be likely to occur on approximately 60 days from December 1 through May 31, but primarily during April and May. Based on the expectation that scouting expeditions would also be prepared to hunt if whales were found, it is assumed for this analysis that hunting could also occur on approximately 60 days each year (Subsection 4.1.3.1, Potential Timing of a Hunt and Number of Hunting Days[Alternative 3]). Although Alternative 3 would include the same limit on the number of whales harvested as Alternative 2, the limit on the number of whales struck would be six instead of seven. It is assumed for this analysis that approximately 36 whales would be exposed to harpoon attempts and 353 would be approached annually (Table 4-1). Compared to the No-action Alternative, under which there would be no hunting, Alternative 3 would likely result in (1) minor short-term increases in tourism on or near the approximately 60 days per year when hunt-related trips would be expected to occur, (2) an increase of four whales annually available for household use by Makah tribal members, (3) negligible changes in whale-watching revenues because of changes in whale behavior as a result of interactions between hunters and whales, (4) minor increases in the potential for interference with commercial shipping and sport and commercial fishing vessels, and (5) an increase in expenditures for management and law enforcement during the likely 60 days with hunt-related trips.

Because both Alternative 2 and Alternative 3 would be expected to result in the same number of days with hunt-related trips, the potential effects on tourist-related business activity under Alternative 3 would likely be the same as those under Alternative 2.

4.6.3.3.1 Tourism
